

Micropower Sampling 8-Bit Serial I/O A/D Converters

FEATURES

- 80 μ A Maximum Supply Current
- 1nA Typical Supply Current in Shutdown
- 8-Pin SOIC Plastic Package
- Single Supply 3V to 9V Operation
- 2.7V and 5V Specified
- Sample-and-Hold
- 16 μ s Conversion Time
- 33kHz Sample Rate
- $\pm 1/2$ LSB Total Unadjusted Error Over Temp
- Direct 3-Wire Interface to Most MPU Serial Ports and All MPU Parallel I/O Ports

APPLICATIONS

- Battery-Operated Systems
- Remote Data Acquisition
- Battery Monitoring
- Battery Gas Gauges
- Temperature Measurement
- Isolated Data Acquisition

DESCRIPTION

The LTC1096/LTC1098 are micropower, 8-bit A/D converters which draw only 80 μ A of supply current when converting. They automatically power down to 1nA typical supply current whenever they are not performing conversions. They are packaged in 8-pin SO packages and operate on 3V to 9V supplies. These 8-bit, switched-capacitor, successive approximation ADCs include sample-and-hold. The LTC1096 has a single differential analog input. The LTC1098 offers a software selectable 2-channel MUX.

On-chip serial ports allow efficient data transfer to a wide range of microprocessors and microcontrollers over three wires. This, coupled with micropower consumption, makes remote location possible and facilitates transmitting data through isolation barriers.

These circuits can be used in ratiometric applications or with an external reference. The high impedance analog inputs and the ability to operate with reduced spans (below 1V full scale) allow direct connection to sensors and transducers in many applications, eliminating the need for gain stages.

All grades are specified with offset and linearity errors of ± 0.5 LSB maximum over temperature. The A grade devices are specified with total unadjusted error of ± 0.5 LSB maximum over temperature.

TYPICAL APPLICATION

10 μ W, S-8 Package, 8-Bit A/D
 Samples at 200Hz and Runs Off a 3V Battery

The ● denotes specifications which apply over the operating temperature range.

Note 1: Absolute maximum ratings are those values beyond which the life of a device may be impaired.

Note 2: All voltage values are with respect to GND.

Note 3: For the 8-lead plastic DIP, consult the factory.

Note 4: Linearity error is specified between the actual and points of the A/D transfer curve.

Note 5: Total unadjusted error includes offset, full scale, linearity, multiplexer and hold step errors.

Note 6: Two on-chip diodes are tied to each reference and analog input which will conduct for reference or analog input voltages one diode drop below GND or one diode drop above V_{CC} . This spec allows 50mV forward

bias of either diode for $2.7V \leq V_{CC} \leq 5.5V$. This means that as long as the reference or analog input does not exceed the supply voltage by more than 50mV, the output code will be correct. To achieve an absolute 0V to 5V input voltage range will therefore require a minimum supply voltage of 4.950V over initial tolerance, temperature variations and loading. For $5.5V < V_{CC} \leq 9V$, reference and analog input range cannot exceed 5.55V. If reference and analog input range are greater than 5.55V, the output code will not be guaranteed to be correct.

Note 7: The supply voltage range for the LTC1096 is from 2.7V to 9V, but the supply voltage range for the LTC1098 is only from 2.7V to 6V.

Note 8: Channel leakage current is measured after the channel selection.

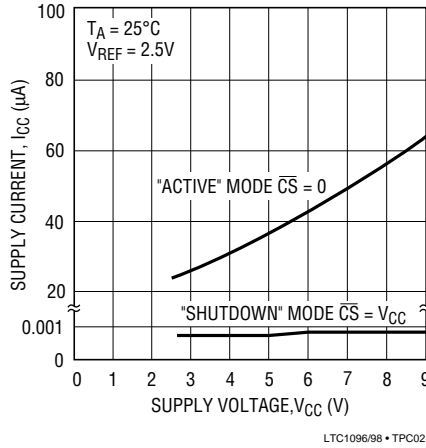

Note 9: These specifications are either correlated from 5V specifications or guaranteed by design.

APPLICATIONS INFORMATION

OVERVIEW

The LTC1096 and LTC1098 are 8-bit micropower, switched-capacitor A/D converters. These sampling ADCs typically draw 100µA of supply current when sampling at 33kHz. Supply current drops linearly as the sample rate is reduced (see Supply Current vs Sample Rate on page 1). The ADCs automatically power down when not performing conversion, drawing only leakage current. They are packaged in 8-pin SO packages. The LTC1096 operates on a single supply ranging from 2.7V to 9V while the LTC1098 operates from 2.7V to 6V supplies.

Both the LTC1096 and the LTC1098 comprise an 8-bit, switched-capacitor ADC, a sample-and-hold, and a serial port (see Block Diagram). Although they share the same

basic design, the LTC1096 and LTC1098 differ in some respects. The LTC1096 has a differential input and has an external reference input pin. It can measure signals floating on a DC common mode voltage and can operate with reduced spans down to 250mV. Reducing the span allows it to achieve 1mV resolution. The LTC1098 has a 2-channel input multiplexer and can convert either channel with respect to ground or the difference between the two.

SERIAL INTERFACE

The LTC1098 communicates with microprocessors and other external circuitry via a synchronous, half duplex, 4-wire serial interface while the LTC1096 uses a 3-wire interface (see Operating Sequence in Figure 1 and 2).

APPLICATIONS INFORMATION

Power Down and Wake-Up Time

The LTC1096/LTC1098 draw power when the \overline{CS} pin is low and shut themselves down when that pin is high. In order to have a correct conversion result, a $10\mu\text{s}$ wake-up time must be provided from \overline{CS} falling to the first falling clock (CLK) after the first rising CLK for the LTC1096 and from \overline{CS} falling to the MSBF bit CLK falling for the LTC1098 (see Operating Sequence). If the LTC1096/LTC1098 are running with clock frequency less than or equal to 100kHz , the wake-up time is inherently provided.

Example

Two cases are shown at right to illustrate the relationship among wake-up time, setup time and CLK frequency for the LTC1096.

In Case 1 the clock frequency is 100kHz . One clock cycle is $10\mu\text{s}$ which can be the wake-up time, while half of that can be the setup time. In Case 2 the clock frequency is 50kHz , half of the clock cycle plus the setup time ($=1\mu\text{s}$) can be the wake-up time. If the CLK frequency is higher than 100kHz , Figure 1 shows the relationship between the wakeup time and setup time.

CASE 1. Timing Diagram

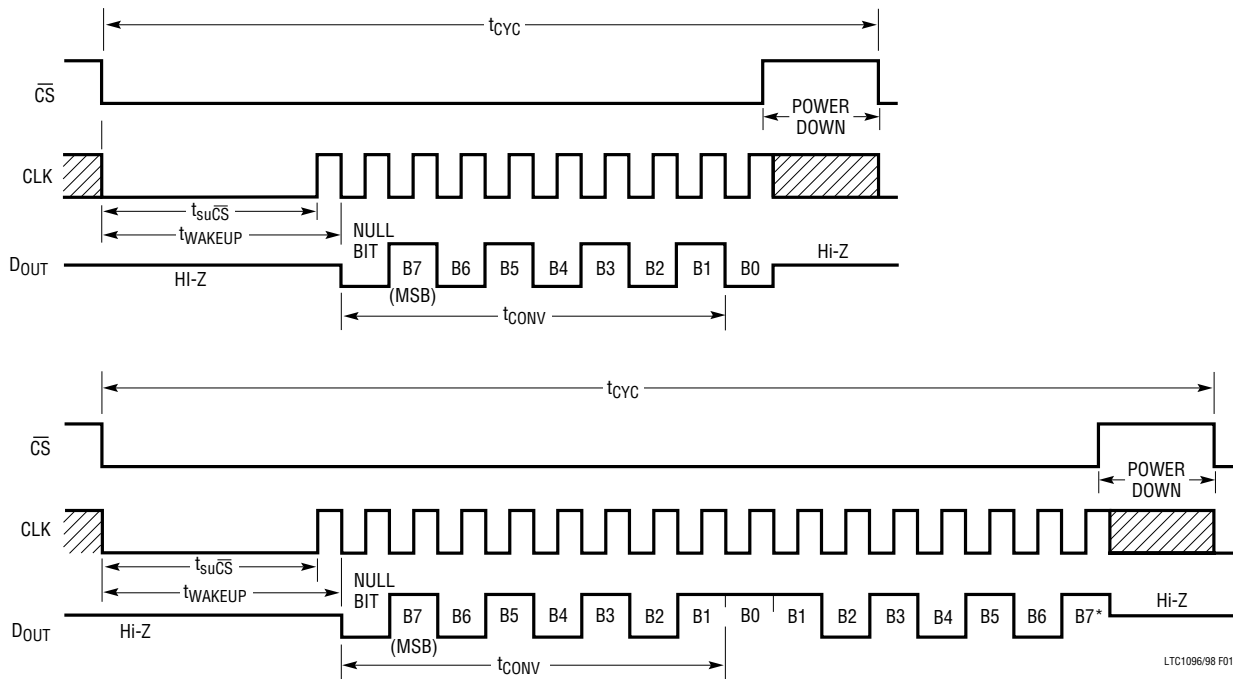

CASE 2. Timing Diagram

LTC1096/98 • AI Ex.

The wakeup time is inherently provided for the LTC1098 with setup time = $1\mu\text{s}$ (see Figure 2).

Data Transfer

The CLK synchronizes the data transfer with each bit being transmitted on the falling CLK edge and captured on the rising CLK edge in both transmitting and receiving systems.

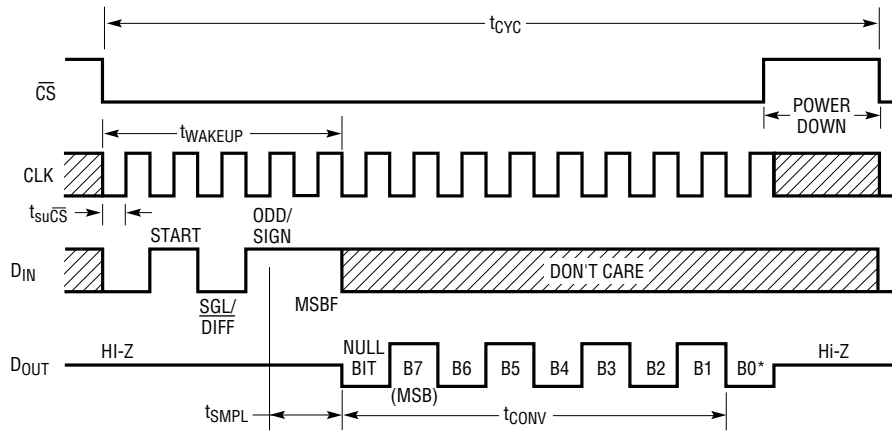

LTC1096/98 F01

*AFTER COMPLETING THE DATA TRANSFER, IF FURTHER CLOCKS ARE APPLIED WITH \overline{CS} LOW, THE ADC WILL OUTPUT ZEROS INDEFINITELY.

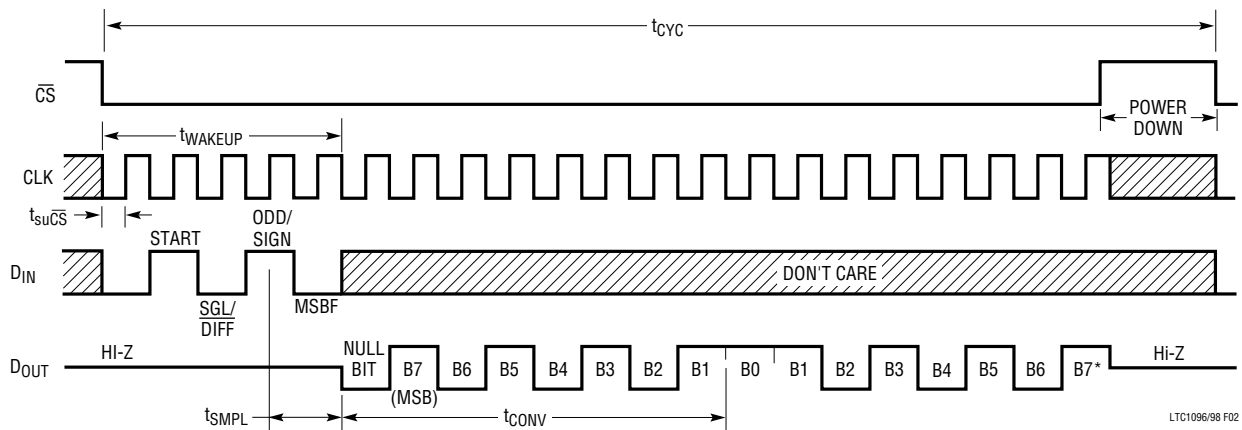

Figure 1. LTC1096 Operating Sequence

APPLICATIONS INFORMATION

MSB-FIRST DATA (MSBF = 1)

MSB-FIRST DATA (MSBF = 0)

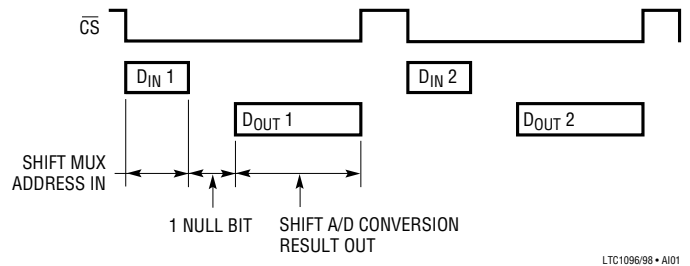

*AFTER COMPLETING THE DATA TRANSFER, IF FURTHER CLOCKS ARE APPLIED WITH \overline{CS} LOW, THE ADC WILL OUTPUT ZEROS INDEFINITELY.

Figure 2. LTC1098 Operating Sequence Example: Differential Inputs (CH^+ , CH^-)

tems. The LTC1098 first receives input data and then transmits back the A/D conversion result (half duplex). Because of the half duplex operation, D_{IN} and D_{OUT} may be tied together allowing transmission over just 3 wires: \overline{CS} , CLK and DATA (D_{IN}/D_{OUT}).

Data transfer is initiated by a falling chip select (\overline{CS}) signal. After \overline{CS} falls the LTC1098 looks for a start bit. After the start bit is received, the 3-bit input word is shifted into the D_{IN} input which configures the LTC1098 and starts the conversion. After one null bit, the result of the conversion is output on the D_{OUT} line. At the end of the data exchange \overline{CS} should be brought high. This resets the LTC1098 in preparation for the next data exchange.

The LTC1096 does not require a configuration input word and has no D_{IN} pin. A falling \overline{CS} initiates data transfer as shown in the LTC1096 operating sequence. After \overline{CS} falls, the first CLK pulse enables D_{OUT} . After one null bit, the A/D conversion result is output on the D_{OUT} line. Bringing \overline{CS} high resets the LTC1096 for the next data exchange.

APPLICATIONS INFORMATION

Input Data Word

The LTC1096 requires no D_{IN} word. It is permanently configured to have a single differential input. The conversion result, in which output on the D_{OUT} line is MSB first sequence, followed by LSB sequence providing easy interface to MSB or LSB first serial ports.

The LTC1098 clocks data into the D_{IN} input on the rising edge of the clock. The input data words are defined as follows:

Start Bit

The first “logical one” clocked into the D_{IN} input after \overline{CS} goes low is the start bit. The start bit initiates the data transfer. The LTC1098 will ignore all leading zeros which precede this logical one. After the start bit is received, the remaining bits of the input word will be clocked in. Further inputs on the D_{IN} pin are then ignored until the next \overline{CS} cycle.

Multiplexer (MUX) Address

The bits of the input word following the START bit assign the MUX configuration for the requested conversion. For a given channel selection, the converter will measure the voltage between the two channels indicated by the + and – signs in the selected row of the following tables. In single-ended mode, all input channels are measured with respect to GND.

LTC1098 Channel Selection

	MUX ADDRESS		CHANNEL #		GND
	SGL/DIFF	ODD/SIGN	0	1	
Single-ended MUX mode	1	0	+	–	
	1	1	–	+	
Differential MUX mode	0	0	+	–	
	0	1	–	+	

LTC1096/8 • AI03

MSB First/LSB First (MSBF)

The output data of the LTC1098 is programmed for MSB first or LSB first sequence using the MSBF bit. When the MSBF bit is a logical one, data will appear on the D_{OUT} line in MSB first format. Logical zeros will be filled in indefinitely following the last data bit. When the

MSBF bit is a logical zero, LSB first data will follow the normal MSB first data on the D_{OUT} line. (see Operating Sequence)

Unipolar Transfer Curve

The LTC1096/LTC1098 are permanently configured for unipolar only. The input span and code assignment for this conversion type are shown in the following figures.

Operation with D_{IN} and D_{OUT} Tied Together

The LTC1098 can be operated with D_{IN} and D_{OUT} tied together. This eliminates one of the lines required to communicate to the microprocessor (MPU). Data is transmitted in both directions on a single wire. The processor pin connected to this data line should be configurable as either an input or an output. The LTC1098 will take control of the data line and drive it low on the 4th falling CLK edge after the start bit is received (see Figure 3). Therefore the processor port line must be switched to an input before this happens, to avoid a conflict.

In the Typical Applications section, there is an example of interfacing the LTC1098 with D_{IN} and D_{OUT} tied together to the Intel 8051 MPU.

APPLICATIONS INFORMATION

Figure 3. LTC1098 Operation with D_{IN} and D_{OUT} Tied Together

ACHIEVING MICROPOWER PERFORMANCE

With typical operating currents of $40\mu A$ and automatic shutdown between conversions, the LTC1096/LTC1098 achieves extremely low power consumption over a wide range of sample rates (see Figure 4). In systems that convert continuously, the LTC1096/LTC1098 will draw its normal operating power continuously. Figure 5 shows that the typical current varies from $40\mu A$ at clock rates below $50kHz$ to $100\mu A$ at $500kHz$. Several things must be taken into account to achieve such a low power consumption.

Figure 4. Automatic Power Shutdown Between Conversions Allows Power Consumption to Drop with Sample Rate.

Shutdown

Figures 1 and 2 show the operating sequence of the LTC1096/LTC1098. The converter draws power when the

Figure 5. After a conversion, when the microprocessor drives \overline{CS} high, the ADC automatically shuts down until the next conversion. The supply current, which is very low during conversions, drops to zero in shutdown.

\overline{CS} pin is low and powers itself down when that pin is high. If the \overline{CS} pin is not taken to ground when it is low and not taken to supply voltage when it is high, the input buffers of the converter will draw current. This current may be larger than the typical supply current. It is worthwhile to bring the \overline{CS} pin all the way to ground when it is low and all the way to supply voltage when it is high to obtain the lowest supply current.

When the \overline{CS} pin is high (= supply voltage), the converter is in shutdown mode and draws only leakage current. The status of the D_{IN} and CLK input have no effect on supply

APPLICATIONS INFORMATION

current during this time. There is no need to stop D_{IN} and CLK with $\overline{CS} = \text{high}$, except the MPU may benefit.

Minimize \overline{CS} Low Time

In systems that have significant time between conversions, lowest power drain will occur with the minimum \overline{CS} low time. Bringing \overline{CS} low, waiting $10\mu\text{s}$ for the wake up time, transferring data as quickly as possible, and then bringing it back high will result in the lowest current drain. This minimizes the amount of time the device draws power. Even though the device draws more power at high clock rates, the net power is less because the device is on for a shorter time.

D_{OUT} Loading

Capacitive loading on the digital output can increase power consumption. A 100pF capacitor on the D_{OUT} pin can more than double the $100\mu\text{A}$ supply current drain at a 500kHz clock frequency. An extra $100\mu\text{A}$ or so of current goes into charging and discharging the load capacitor. The same goes for digital lines driven at a high frequency by any logic. The C_{xVxf} currents must be evaluated and the troublesome ones minimized.

Lower Supply Voltage

Another way to lower the power consumption is to operate these two ADCs on a single 2.7V supply. The supply current is reduced by 30% compared to that on a 5V supply and the power consumption is 60% lower than that on a 5V supply (see typical curve of Supply Current vs Supply Voltage).

OPERATING ON OTHER THAN 5V SUPPLIES

The LTC1096 operates from 2.7V to 9V supplies and the LTC1098 operates from 2.7V to 6V supplies. To operate the LTC1096/LTC1098 on other than 5V supplies, a few things must be kept in mind.

Wake Up Time

A $10\mu\text{s}$ wake up time must be provided for the ADCs to convert correctly on a 5V supply. The wake up time is typically less than $3\mu\text{s}$ over the supply voltage range (see typical curve of Wake Up Time vs Supply Voltage). With

$10\mu\text{s}$ wake up time provided over the supply range, the ADCs will have adequate time to wake up and acquire input signals.

Input Logic Levels

The input logic levels of \overline{CS} , CLK and D_{IN} are made to meet TTL on 5V supply. When the supply voltage varies, the input logic levels also change. For these two ADCs to sample and convert correctly, the digital inputs have to meet logic low and high levels relative to the operating supply voltage (see typical curve of Digital Input Logic Threshold vs Supply Voltage). If achieving micropower consumption is desirable, the digital inputs must go rail-to-rail between supply voltage and ground (see ACHIEVING MICROPOWER PERFORMANCE section).

Clock Frequency

The maximum recommended clock frequency is 500kHz for the LTC1096/LTC1098 running off a 5V supply. With the supply voltage changing, the maximum clock frequency for the devices also changes (see the typical curve of Maximum Clock Rate vs Supply Voltage). If the maximum clock frequency is used, care must be taken to ensure that the device converts correctly.

Mixed Supplies

It is possible to have a microprocessor running off a 5V supply and communicate with the LTC1096/LTC1098 operating on 3V or 9V supplies. The requirement to achieve this is that the outputs of \overline{CS} , CLK and D_{IN} from the MPU have to be able to trip the equivalent inputs of the ADCs and the output of D_{OUT} from the ADCs must be able to toggle the equivalent input of the MPU (see typical curve of Digital Input Logic Threshold vs Supply Voltage). With the LTC1096 operating on a 9V supply, the output of D_{OUT} may go between 0V and 9V . The 9V output may damage the MPU running off a 5V supply. The way to get around this possibility is to have a resistor divider on D_{OUT} (Figure 6) and connect the center point to the MPU input. It should be noted that to get full shutdown, the \overline{CS} input of the LTC1096/LTC1098 must be driven to the V_{CC} voltage. This would require adding a level shift circuit to the \overline{CS} signal in Figure 6.

APPLICATIONS INFORMATION

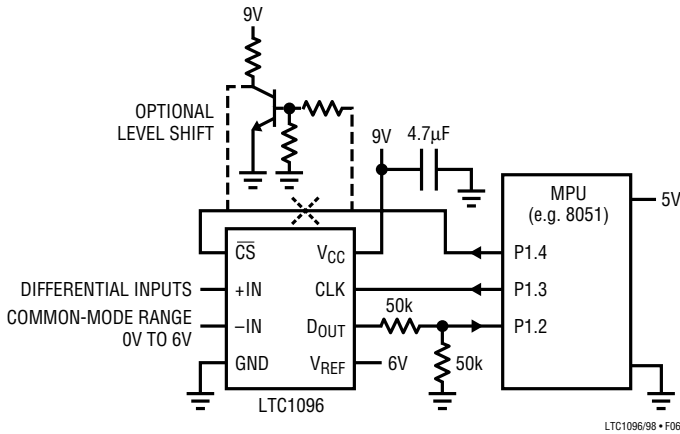

Figure 6. Interfacing a 9V Powered LTC1096 to a 5V System

BOARD LAYOUT CONSIDERATIONS

Grounding and Bypassing

The LTC1096/LTC1098 should be used with an analog ground plane and single point grounding techniques. The GND pin should be tied directly to the ground plane.

The V_{CC} pin should be bypassed to the ground plane with a 1µF tantalum with leads as short as possible. If power supply is clean, the LTC1096/LTC1098 can also operate

with smaller 0.1µF surface mount or ceramic bypass capacitors. All analog inputs should be referenced directly to the single point ground. Digital inputs and outputs should be shielded from and/or routed away from the reference and analog circuitry.

SAMPLE-AND-HOLD

Both the LTC1096 and the LTC1098 provide a built-in sample-and-hold (S&H) function to acquire signals. The S&H of the LTC1096 acquires input signals from “+” input relative to “-” input during the t_{WAKEUP} time (see Figure 1). However, the S&H of the LTC1098 can sample input signals in the single-ended mode or in the differential inputs during the t_{SAMPL} time (see Figure 7).

Single-Ended Inputs

The sample-and-hold of the LTC1098 allows conversion of rapidly varying signals. The input voltage is sampled during the t_{SAMPL} time as shown in Figure 7. The sampling interval begins as the bit preceding the MSBF bit is shifted in and continues until the falling CLK edge after the MSBF bit is received. On this falling edge, the S&H goes into hold mode and the conversion begins.

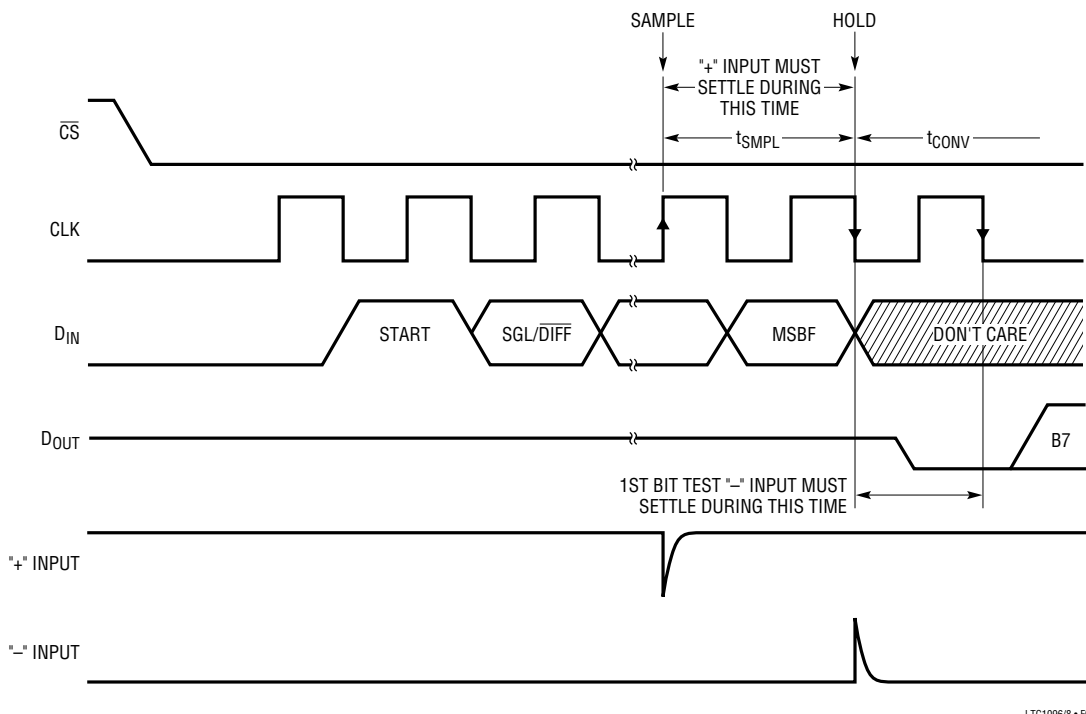

Figure 7. LTC1098 “+” and “-” Input Settling Windows

APPLICATIONS INFORMATION

Differential Inputs

With differential inputs, the ADC no longer converts just a single voltage but rather the difference between two voltages. In this case, the voltage on the selected “+” input is still sampled and held and therefore may be rapidly time varying just as in single-ended mode. However, the voltage on the selected “-” input must remain constant and be free of noise and ripple throughout the conversion time. Otherwise, the differencing operation may not be performed accurately. The conversion time is 8 CLK cycles. Therefore, a change in the “-” input voltage during this interval can cause conversion errors. For a sinusoidal voltage on the “-” input this error would be:

$$V_{\text{ERROR (MAX)}} = V_{\text{PEAK}} \times 2 \times \pi \times f(\text{“-”}) \times 8/f_{\text{CLK}}$$

Where $f(\text{“-”})$ is the frequency of the “-” input voltage, V_{PEAK} is its peak amplitude and f_{CLK} is the frequency of the CLK. In most cases V_{ERROR} will not be significant. For a 60Hz signal on the “-” input to generate a 1/4LSB error (5mV) with the converter running at CLK = 500kHz, its peak value would have to be 750mV.

ANALOG INPUTS

Because of the capacitive redistribution A/D conversion techniques used, the analog inputs of the LTC1096/LTC1098 have capacitive switching input current spikes. These current spikes settle quickly and do not cause a problem. However, if large source resistances are used or if slow settling op amps drive the inputs, care must be taken to insure that the transients caused by the current spikes settle completely before the conversion begins.

“+” Input Settling

The input capacitor of the LTC1096 is switched onto “+” input during the wake up time (see Figure 1) and samples the input signal within that time. However, the input capacitor of the LTC1098 is switched onto “+” input during the sample phase (t_{SMPL} , see Figure 7). The sample phase is 1 1/2 CLK cycles before conversion starts. The voltage on the “+” input must settle completely within t_{WAKEUP} or t_{SMPL} for the LTC1096 or the LTC1098 respectively. Minimizing R_{SOURCE^+} and C1 will improve the input settling time. If a large “+” input source resistance must be

used, the sample time can be increased by using a slower CLK frequency.

“-” Input Settling

At the end of the t_{WAKEUP} or t_{SMPL} , the input capacitor switches to the “-” input and conversion starts (see Figures 1 and 7). During the conversion, the “+” input voltage is effectively “held” by the sample-and-hold and will not affect the conversion result. However, it is critical that the “-” input voltage settles completely during the first CLK cycle of the conversion time and be free of noise. Minimizing R_{SOURCE^-} and C2 will improve settling time. If a large “-” input source resistance must be used, the time allowed for settling can be extended by using a slower CLK frequency.

Input Op Amps

When driving the analog inputs with an op amp it is important that the op amp settle within the allowed time (see Figure 7). Again, the “+” and “-” input sampling times can be extended as described above to accommodate slower op amps. Most op amps, including the LT1006 and LT1413 single supply op amps, can be made to settle well even with the minimum settling windows of 3 μ s (“+” input) which occur at the maximum clock rate of 500kHz.

Source Resistance

The analog inputs of the LTC1096/LTC1098 look like a 25pF capacitor (C_{IN}) in series with a 500 Ω resistor (R_{ON}) as shown in Figure 8. C_{IN} gets switched between the selected “+” and “-” inputs once during each conversion cycle. Large external source resistors and capacitances will slow the settling of the inputs. It is important that the

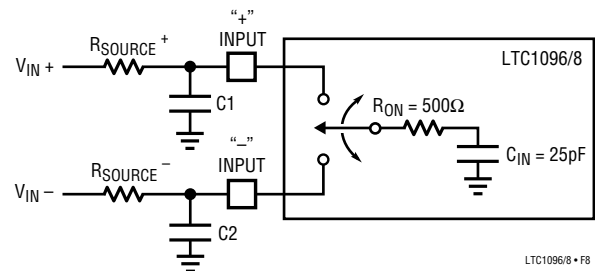

Figure 8. Analog Input Equivalent Circuit

APPLICATIONS INFORMATION

overall RC time constants be short enough to allow the analog inputs to completely settle within the allowed time.

RC Input Filtering

It is possible to filter the inputs with an RC network as shown in Figure 9. For large values of C_F (e.g., $1\mu\text{F}$), the capacitive input switching currents are averaged into a net DC current. Therefore, a filter should be chosen with a small resistor and large capacitor to prevent DC drops across the resistor. The magnitude of the DC current is approximately $I_{DC} = 25\text{pF} \times V_{IN}/t_{CYC}$ and is roughly proportional to V_{IN} . When running at the minimum cycle time of $29\mu\text{s}$, the input current equals $4.3\mu\text{A}$ at $V_{IN} = 5\text{V}$. In this case, a filter resistor of 390Ω will cause 0.1LSB of full-scale error. If a larger filter resistor must be used, errors can be eliminated by increasing the cycle time.

Figure 9. RC Input Filtering

Input Leakage Current

Input leakage currents can also create errors if the source resistance gets too large. For instance, the maximum input leakage specification of $1\mu\text{A}$ (at 125°C) flowing through a source resistance of 3.9k will cause a voltage drop of 3.9mV or 0.2LSB . This error will be much reduced at lower temperatures because leakage drops rapidly (see typical curve of Input Channel Leakage Current vs Temperature).

REFERENCE INPUTS

The voltage on the reference input of the LTC1096 defines the voltage span of the A/D converter. The reference input transient capacitive switching currents due to the switched-capacitor conversion technique (see Figure 10). During each bit test of the conversion (every CLK cycle), a capacitive current spike will be generated on the reference pin by the ADC. These current spikes settle quickly and do not cause a problem.

Using a slower CLK will allow more time for the reference to settle. Even at the maximum CLK rate of 500kHz most references and op amps can be made to settle within the $2\mu\text{s}$ bit time.

Figure 10. Reference Input Equivalent Circuit

Reduced Reference Operation

The minimum reference voltage of the LTC1098 is limited to 2.7V because the V_{CC} supply and reference are internally tied together. However, the LTC1096 can operate with reference voltages below 1V .

The effective resolution of the LTC1096 can be increased by reducing the input span of the converter. The LTC1096 exhibits good linearity and gain over a wide range of reference voltages (see typical curves of Linearity and Full Scale Error vs Reference Voltage). However, care must be taken when operating at low values of V_{REF} because of the reduced LSB step size and the resulting higher accuracy requirement placed on the converter. The following factors must be considered when operating at low V_{REF} values.

1. Offset
2. Noise
3. Conversion speed (CLK frequency)

Offset with Reduced V_{REF}

The offset of the LTC1096 has a larger effect on the output code when the ADC is operated with reduced reference voltage. The offset (which is typically a fixed voltage) becomes a larger fraction of an LSB as the size of the LSB is reduced. The typical curve of Unadjusted Offset Error vs Reference Voltage shows how offset in LSBs is related to reference voltage for a typical value of V_{OS} . For example, a V_{OS} of 2mV which is 0.1LSB with a 5V reference becomes 0.5LSB with a 1V reference and 2.5LSBs with a

APPLICATIONS INFORMATION

0.2V reference. If this offset is unacceptable, it can be corrected digitally by the receiving system or by offsetting the “–” input of the LTC1096.

Noise with Reduced V_{REF}

The total input referred noise of the LTC1096 can be reduced to approximately 1mV peak-to-peak using a ground plane, good bypassing, good layout techniques and minimizing noise on the reference inputs. This noise is insignificant with a 5V reference but will become a larger fraction of an LSB as the size of the LSB is reduced.

For operation with a 5V reference, the 1mV noise is only 0.05LSB peak-to-peak. In this case, the LTC1096 noise will contribute virtually no uncertainty to the output code. However, for reduced references, the noise may become a significant fraction of an LSB and cause undesirable jitter in the output code. For example, with a 1V reference, this same 1mV noise is 0.25LSB peak-to-peak. This will reduce the range of input voltages over which a stable output code can be achieved by 1LSB. If the reference is further reduced to 200mV, the 1mV noise becomes equal to 1.25LSBs and a stable code may be difficult to achieve. In this case averaging readings may be necessary.

This noise data was taken in a very clean setup. Any setup induced noise (noise or ripple on V_{CC} , V_{REF} or V_{IN}) will add to the internal noise. The lower the reference voltage to be used, the more critical it becomes to have a clean, noise free setup.

Conversion Speed with Reduced V_{REF}

With reduced reference voltages, the LSB step size is reduced and the LTC1096 internal comparator overdrive is reduced. Therefore, it may be necessary to reduce the maximum CLK frequency when low values of V_{REF} are used.

Input Divider

It is OK to use an input divider on the reference input of the LTC1096 as long as the reference input can be made to settle within the bit time at which the clock is running. When using a larger value resistor divider on the reference

input the “–” input should be matched with an equivalent resistance.

Bypassing Reference Input with Divider

Bypassing the reference input with a divider is also possible. However care must be taken to make sure that the DC voltage on the reference input will not drop too much below the intended reference voltage.

AC PERFORMANCE

Two commonly used figures of merit for specifying the dynamic performance of the ADCs in digital signal processing applications are the Signal-to-Noise Ratio (SNR) and the “effective number of bits (ENOB).

Signal-to-Noise Ratio

The Signal-to-Noise Ratio (SNR) is the ratio between the RMS amplitude of the fundamental input frequency to the RMS amplitude of all other frequency components at the A/D output. This includes distortion as well as noise products and for this reason it is sometimes referred to as Signal-to-Noise + Distortion [S/(N + D)]. The output is band limited to frequencies from DC to one half the sampling frequency. Figure 11 shows spectral content from DC to 15.625kHz which is 1/2 the 31.25kHz sampling rate.

Figure 11. This clean FFT of an 11.8kHz input shows remarkable performance for an ADC that draws only 100 μ A when sampling at the 31.25kHz rate.

APPLICATIONS INFORMATION

Effective Number of Bits

The effective number of bits (ENOBs) is a measurement of the resolution of an A/D and is directly related to the $S/(N + D)$ by the equation:

$$ENOB = [S/(N + D) - 1.76]/6.02$$

where $S/(N + D)$ is expressed in dB. At the maximum sampling rate of 33kHz the LTC1096 maintains 7.5 ENOBs or better to 40kHz. Above 40kHz the ENOBs gradually decline, as shown in Figure 12, due to increasing second harmonic distortion. The noise floor remains approximately 70dB.

Figure 12. Dynamic Accuracy is Maintained Up to an Input Frequency of 40kHz

TYPICAL APPLICATIONS

MICROPROCESSOR INTERFACES

The LTC1096/LTC1098 can interface directly (without external hardware to most popular microprocessor (MPU) synchronous serial formats (see Table 1). If an MPU without a dedicated serial port is used, then 3 or 4 of the MPU's parallel port lines can be programmed to form the serial link to the LTC1096/LTC1098. Included here is one serial interface example and one example showing a parallel port programmed to form the serial interface.

Motorola SPI (MC68HC05C4, CM68HC11)

The MC68HC05C4 has been chosen as an example of an MPU with a dedicated serial port. This MPU transfer data MSB first and in 8-bit increments. With two 8-bit transfers, the A/D result is read into the MPU. The first 8-bit transfer sends the D_{IN} word to the LTC1098 and clocks into the processor. The second 8-bit transfer clocks the A/D conversion result, B7 through B0, into the MPU.

ANDing the first MUP received byte with 00Hex clears the first byte. Notice how the position of the start bit in the first MPU transmit word is used to position the A/D result right justified in two memory locations.

Interfacing to the Parallel Port of the INTEL 8051 Family

The Intel 8051 has been chosen to demonstrate the interface between the LTC1098 and parallel port microprocessors. Normally the \overline{CS} , CLK and D_{IN} signals would be generated on 3 port lines and the D_{OUT} signal read on a 4th port line. This works very well. However, we will

demonstrate here an interface with the D_{IN} and D_{OUT} of the LTC1098 tied together as described in the SERIAL INTERFACE section. This saves one wire.

The 8051 first sends the start bit and MUX address to the LTC1098 over the data line connected to P1.2. Then P1.2 is reconfigured as an input (by writing to it a one) and the 8051 reads back the 8-bit A/D result over the same data line.

A “Quick Look” Circuit for the LTC1096

Users can get a quick look at the function and timing of the LTC1096 by using the following simple circuit (Figure 13). V_{REF} is tied to V_{CC} . V_{IN} is applied to the +IN input and the -IN input is tied to the ground. \overline{CS} is driven at 1/16 the clock rate by the 74C161 and D_{OUT} outputs the data. The output data from the D_{OUT} pin can be viewed on an oscilloscope that is set up to trigger on the falling edge of \overline{CS} (Figure 14). Note the LSB data is partially clocked out before \overline{CS} goes high.

Figure 15 shows a temperature measurement system. The LTC1096 is connected directly to the low cost silicon temperature sensor. The voltage applied to the V_{REF} pin adjusts the full scale of the A/D to the output range of the

sensor. The zero point of the converter is matched to the zero output voltage of the sensor by the voltage on the LTC1096’s negative input.

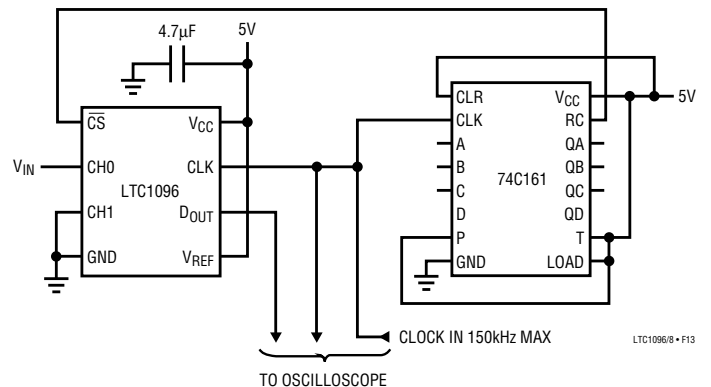

Figure 13. “Quick Look” Circuit for the LTC1096

TYPICAL APPLICATIONS

Figure 14. Scope Trace the LTC1096 “Quick Look” Circuit Showing A/D Output 10101010 (AA_{HEX})

Figure 15. The LTC1096’s high impedance input connects directly to this temperature sensor, eliminating signal conditioning circuitry in this 0°C to 70°C thermometer.

Remote or Isolated Systems

Figure 16 shows a floating system that sends data to a grounded host system. The floating circuitry is isolated by two opto-isolators and powered by a simple capacitor diode charge pump. The system has very low power requirements because the LTC1096 shuts down between conversions and the opto-isolators draw power only when data is being transferred. The system consumes only 50μA at a sample rate of 10Hz (1ms on-time and 99ms off-time). This is easily within the current supplied by the charge pump running at 5MHz. If a truly isolated system is required, the system’s low power simplifies generating an isolated supply or powering the system from a battery.

A/D Conversion for 3V Systems

The LTC1096/LTC1098 are ideal for 3V systems. Figure 17 shows a 3V to 6V battery current monitor which draws only 70μA from the battery it monitors. The battery current is sensed with the 0.02Ω resistor and amplified by the LT1178. The LTC1096 digitizes the amplifier output and sends it to the microprocessor in serial format. The LT1004 provides the full scale reference for the A/D. The other half of the LTC1178 is used to provide low battery detection. The circuit’s 70μA supply current is dominated by the op amps and the reference. The circuit can be located near the battery and data transmitted serially to the microprocessor.

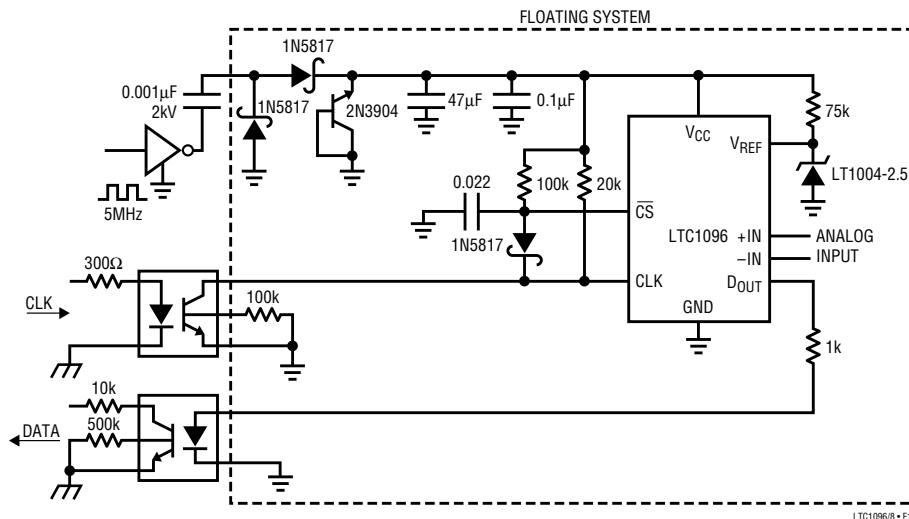

Figure 16. Power for this floating A/D system is provided by a simple capacitor diode charge pump. The two opto-isolators draw no current between samples, turning on only to send the clock and receive data.
