Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
5. Renesas Electronics products are classified according to the following two quality grades: “Standard” and “High Quality”. The intended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below.
   “Standard”: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.
   “High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.
   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.
6. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note 2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

(Rev.4.0-1 November 2017)

General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Handling of Unused Pins

   Handle unused pins in accordance with the directions given under Handling of Unused Pins in the manual.

   ¾ The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

2. Processing at Power-on

   The state of the product is undefined at the moment when power is supplied.

   ¾ The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.
   In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.
   In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

3. Prohibition of Access to Reserved Addresses

   Access to reserved addresses is prohibited.

   ¾ The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

4. Clock Signals

   After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

   ¾ When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

5. Differences between Products

   Before changing from one product to another, i.e. to a product with a different part number, confirm that the change will not lead to problems.

   ¾ The characteristics of Microprocessing unit or Microcontroller unit products in the same group but having a different part number may differ in terms of the internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

11.3.6 Free-Running Comparison Mode 11-13
12. Watchdog Timer 12-1
12.1 Features 12-1
12.2 Input/Output Pin 12-2
12.3 Register Descriptions 12-2
12.3.1 Watchdog Timer Counter (WTCNT) 12-3
12.3.2 Watchdog Timer Control/Status Register (WTCSR) 12-3
12.3.3 Watchdog Reset Control/Status Register (WRCSR) 12-5
12.3.4 Notes on Register Access 12-6
12.4 Usage 12-8
12.4.1 Canceling Software Standby Mode 12-8
12.4.2 Using Watchdog Timer Mode 12-8
12.4.3 Using Interval Timer Mode 12-9
12.5 Usage Notes 12-10
12.5.1 Timer Variation 12-10
12.5.2 Prohibition against Setting H'FF to WTCNT 12-10
12.5.3 Interval Timer Overflow Flag 12-10
12.5.4 System Reset by $\overline{\text{WDTOVF}}$ Signal 12-10
12.5.5 Internal Reset in Watchdog Timer Mode 12-10

13. Realtime Clock 13-1
13.1 Features 13-1
13.2 Input/Output Pin 13-3
13.3 Register Descriptions 13-3
13.3.1 64-Hz Counter (R64CNT) 13-4
13.3.2 Second Counter (RSECCNT) 13-5
13.3.3 Minute Counter (RMINCNT) 13-5
13.3.4 Hour Counter (RHRCNT) 13-6
13.3.5 Day of Week Counter (RWKCNT) 13-6
13.3.6 Day Counter (RDAYCNT) 13-7
13.3.7 Month Counter (RMONCNT) 13-7
13.3.8 Year Counter (RYRCNT) 13-8
13.3.9 Second Alarm Register (RSECAR) 13-8
13.3.10 Minute Alarm Register (RMINAR) 13-9
13.3.11 Hour Alarm Register (RHRAR) 13-9
13.3.12 Day of Week Alarm Register (RWKAR) 13-10
13.3.13 Day Alarm Register (RDAYAR) 13-10
13.3.14 Month Alarm Register (RMONAR) 13-11
13.3.15 Year Alarm Register (RYRAR) 13-11
13.3.16 Control Register 1 (RCR1) 13-12
13.3.17 Control Register 2 (RCR2) 13-13
13.3.18 Control Register 3 (RCR3) 13-14
13.3.19 Control Register 5 (RCR5) 13-14
13.3.20 Frequency Register H/L (RFRH/L) 13-15
13.4 Operation 13-16
13.4.1 Initial Settings of Registers after Power-On and Oscillation Stabilization Time 13-16
13.4.2 Setting Time 13-16
13.4.3 Reading Time 13-17
13.4.4 Alarm Function 13-18
13.5 Usage Notes 13-19
13.5.1 Register Writing during Count Operation 13-19
13.5.2 Use of Realtime Clock Periodic Interrupts 13-19
13.5.3 Transition to Standby Mode after Setting Register 13-19
13.5.4 Usage Notes when Writing to and Reading the Register 13-19
14. Serial Communication Interface with FIFO 14-1
14.1 Features 14-1
14.2 Input/Output Pins 14-3
14.3 Register Descriptions 14-4
14.3.1 Receive Shift Register (SCRSR) 14-5
14.3.2 Receive FIFO Data Register (SCFRDR) 14-5
14.3.3 Transmit Shift Register (SCTSR) 14-6

14.3.4 Transmit FIFO Data Register (SCFTDR) 14-6
14.3.5 Serial Mode Register (SCSMR) 14-7
14.3.6 Serial Control Register (SCSCR) 14-9
14.3.7 Serial Status Register (SCFSR) 14-11
14.3.8 Bit Rate Register (SCBRR) 14-15
14.3.9 FIFO Control Register (SCFCR) 14-19
14.3.10 FIFO Data Count Set Register (SCFDR) 14-21
14.3.11 Serial Port Register (SCSPTR) 14-22
14.3.12 Line Status Register (SCLSR) 14-24
14.3.13 Serial Extension Mode Register (SCEMR) 14-25
14.4 Operation 14-26
14.4.1 Overview 14-26
14.4.2 Operation in Asynchronous Mode 14-28
14.4.3 Operation in Clock Synchronous Mode 14-39
14.5 Interrupts 14-47
14.6 Usage Notes 14-48
14.6.1 SCFTDR Writing and TDFE Flag 14-48
14.6.2 SCFRDR Reading and RDF Flag 14-48
14.6.3 Restriction on Direct Memory Controller Usage 14-48
14.6.4 Break Detection and Processing 14-48
14.6.5 Sending a Break Signal 14-49
14.6.6 Receive Data Sampling Timing and Receive Margin (Asynchronous Mode) 14-49
14.6.7 Selection of Base Clock in Asynchronous Mode 14-50
15. Serial Communications Interface 15-1
15.1 Overview 15-1
15.2 Register Descriptions 15-3
15.2.1 Receive Shift Register (RSR) 15-4
15.2.2 Receive Data Register (RDR) 15-4
15.2.3 Transmit Data Register (TDR) 15-4
15.2.4 Transmit Shift Register (TSR) 15-4
15.2.5 Serial Mode Register (SMR) 15-5
15.2.6 Serial Control Register (SCR) 15-8
15.2.7 Serial Status Register (SSR) 15-12
15.2.8 Smart Card Mode Register (SCMR) 15-16
15.2.9 Bit Rate Register (BRR) 15-17
15.2.10 Serial Extended Mode Register (SEMR) 15-21
15.2.11 Noise Filter Setting Register (SNFR) 15-21
15.2.12 Extended Function Control Register (SECR) 15-22
15.3 Operation in Asynchronous Mode 15-23
15.3.1 Serial Data Transfer Format 15-23
15.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode 15-25

15.3.3 Clock 15-26
15.3.4 CTS and RTS Functions 15-26
15.3.5 SCI Initialization (Asynchronous Mode) 15-27
15.3.6 Serial Data Transmission (Asynchronous Mode) 15-28
15.3.7 Serial Data Reception (Asynchronous Mode) 15-30
15.4 Multi-Processor Communications Function 15-34
15.4.1 Multi-Processor Serial Data Transmission 15-35
15.4.2 Multi-Processor Serial Data Reception 15-36
15.5 Operation in Clock Synchronous Mode 15-39
15.5.1 Clock 15-39
15.5.2 CTS and RTS Functions 15-39
15.5.3 Initialization (Clock Synchronous Mode) 15-40
15.5.4 Serial Data Transmission (Clock Synchronous Mode) 15-41
15.5.5 Serial Data Reception (Clock Synchronous Mode) 15-43
15.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode) 15-46
15.6 Operation in Smart Card Interface Mode 15-47
15.6.1 Sample Connection 15-47
15.6.2 Data Format (Except in Block Transfer Mode) 15-48
15.6.3 Block Transfer Mode 15-50
15.6.4 Receive Data Sampling Timing and Reception Margin 15-50
15.6.5 Initialization (Smart Card Interface Mode) 15-51
15.6.6 Serial Data Transmission (Except in Block Transfer Mode) 15-52
15.6.7 Serial Data Reception (Except in Block Transfer Mode) 15-55
15.6.8 Clock Output Control 15-56
15.7 Noise Cancellation Function 15-58
15.8 Interrupt Sources 15-59
15.8.1 Interrupts in Serial Communications Interface Mode 15-59
15.8.2 Interrupts in Smart Card Interface Mode 15-60
15.9 Usage Notes 15-61
15.9.1 Setting the Module Standby Function 15-61
15.9.2 Break Detection and Processing 15-61
15.9.3 The Mark State and Production of Breaks 15-61
15.9.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode Only) 15-61
15.9.5 Writing Data to TDR 15-61
15.9.6 Restrictions on Clock Synchronous Transmission 15-61
15.9.7 Restrictions on Using DMAC 15-61
15.9.8 Points to Note on Starting Transfer 15-61
15.9.9 SCI Operations during Low Power Consumption State 15-62
15.9.10 External Clock Input in Clock Synchronous Mode 15-64
15.10 IrDA Communications 15-65

15.11 IrDA Register Description 15-66
15.11.1 IrDA Control Register (IRCR) 15-66
15.12 IrDA Operation 15-67
15.12.1 Flow of IrDA Setting 15-67
15.12.2 Transmission 15-67
15.12.3 Reception 15-68
15.12.4 Selection of High-Level Pulse Width 15-68
15.13 Notes on Using the IrDA Module 15-69
15.13.1 Shortest Pulse Width in Reception 15-69
15.13.2 Asynchronous Basic Clock for Serial Communication Interface 15-69
16. Renesas Serial Peripheral Interface 16-1
16.1 Features 16-1
16.2 Input/Output Pins 16-3
16.3 Register Descriptions 16-4
16.3.1 Control Register (SPCR) 16-6
16.3.2 Slave Select Polarity Register (SSLP) 16-7
16.3.3 Pin Control Register (SPPCR) 16-7
16.3.4 Status Register (SPSR) 16-8
16.3.5 Data Register (SPDR) 16-10
16.3.6 Sequence Control Register (SPSCR) 16-10
16.3.7 Sequence Status Register (SPSSR) 16-11
16.3.8 Bit Rate Register (SPBR) 16-11
16.3.9 Data Control Register (SPDCR) 16-12
16.3.10 Clock Delay Register (SPCKD) 16-13
16.3.11 Slave Select Negation Delay Register (SSLND) 16-14
16.3.12 Next-Access Delay Register (SPND) 16-15
16.3.13 Command Register (SPCMD) 16-16
16.3.14 Buffer Control Register (SPBFCR) 16-18
16.3.15 Buffer Data Count Setting Register (SPBFDR) 16-19
16.4 Operation 16-20
16.4.1 Overview of Operations 16-20
16.4.2 Pin Control 16-21
16.4.3 System Configuration Example 16-21
16.4.4 Transfer Format 16-24
16.4.5 Data Format 16-26
16.4.6 Error Detection 16-32
16.4.7 Initialization 16-34
16.4.8 SPI Operation 16-35
16.4.9 Error Handling 16-45
16.4.10 Loopback Mode 16-46
16.4.11 Interrupt Sources 16-46

17. SPI Multi I/O Bus Controller 17-1
17.1 Features 17-1
17.2 Block Diagram 17-2
17.3 Input/Output Pins 17-3
17.4 Register Descriptions 17-4
17.4.1 Common Control Register (CMNCR) 17-5
17.4.2 SSL Delay Register (SSLDR) 17-8
17.4.3 Bit Rate Register (SPBCR) 17-9
17.4.4 Data Read Control Register (DRCR) 17-11
17.4.5 Data Read Command Setting Register (DRCMR) 17-12
17.4.6 Data Read Extended Address Setting Register (DREAR) 17-13
17.4.7 Data Read Option Setting Register (DROPR) 17-14
17.4.8 Data Read Enable Setting Register (DRENR) 17-15
17.4.9 SPI Mode Control Register (SMCR) 17-17
17.4.10 SPI Mode Command Setting Register (SMCMR) 17-18
17.4.11 SPI Mode Address Setting Register (SMADR) 17-18
17.4.12 SPI Mode Option Setting Register (SMOPR) 17-19
17.4.13 SPI Mode Enable Setting Register (SMENR) 17-20
17.4.14 SPI Mode Read Data Register 0 (SMRDR0) 17-22
17.4.15 SPI Mode Read Data Register 1 (SMRDR1) 17-22
17.4.16 SPI Mode Write Data Register 0 (SMWDR0) 17-23
17.4.17 SPI Mode Write Data Register 1 (SMWDR1) 17-23
17.4.18 Common Status Register (CMNSR) 17-24
17.4.19 SPI AC Input Characteristics Adjustment Register (CKDLY) (RZ/A1LU only) 17-25
17.4.20 Data Read Dummy Cycle Setting Register (DRDMCR) 17-26
17.4.21 Data Read DDR Enable Register (DRDRENR) (RZ/A1LU only) 17-27
17.4.22 SPI Mode Dummy Cycle Setting Register (SMDMCR) 17-28
17.4.23 SPI Mode DDR Enable Register (SMDRENR) (RZ/A1LU only) 17-29
17.4.24 SPI AC Output Characteristics Adjustment Register (SPODLY) (RZ/A1LU only) 17-30
17.5 Operation 17-31
17.5.1 System Configuration 17-31
17.5.2 Address Map 17-32
17.5.3 32-bit Serial Flash Addresses 17-32
17.5.4 Data Alignment 17-33
17.5.5 Operating Modes 17-34
17.5.6 External Address Space Read Mode 17-34
17.5.7 Read Cache 17-39
17.5.8 SPI Operating Mode 17-40
17.5.9 Transfer Format 17-43
17.5.10 Data Format 17-45
17.5.11 Data Pin Control 17-50

17.5.12 SPBSSL Pin Control....17-52
17.5.13 Flags....17-52
17.6 Usage Notes....17-53
17.6.1 Notes on Transfer to Read Data in SPI Operating Mode....17-53
17.6.2 Notes on Starting Transfer from the SPBSSL Retained State in SPI Operating Mode....17-53
18. I2C Bus Interface....18-1
18.1 Features....18-1
18.1.1 Channels....18-1
18.1.2 Register Base Addresses....18-1
18.1.3 External I/O Signals....18-2
18.2 Overview....18-3
18.2.1 Functional Overview....18-3
18.2.2 Block Diagram....18-5
18.3 Registers....18-7
18.3.1 RIICnCR1 — I2C Bus Control Register 1....18-7
18.3.2 RIICnCR2 — I2C Bus Control Register 2....18-10
18.3.3 RIICnMR1 — I2C Bus Mode Register 1....18-14
18.3.4 RIICnMR2 — I2C Bus Mode Register 2....18-16
18.3.5 RIICnMR3 — I2C Bus Mode Register 3....18-18
18.3.6 RIICnFER — I2C Bus Function Enable Register....18-21
18.3.7 RIICnSER — I2C Bus Status Enable Register....18-23
18.3.8 RIICnIER — I2C Bus Interrupt Enable Register....18-25
18.3.9 RIICnSR1 — I2C Bus Status Register 1....18-27
18.3.10 RIICnSR2 — I2C Bus Status Register 2....18-30
18.3.11 RIICnSARy — I2C Slave Address Register y (y = 0 to 2)....18-35
18.3.12 RIICnBRL — I2C Bus Bit Rate Low-Level Register....18-37
18.3.13 RIICnBRH — I2C Bus Bit Rate High-Level Register....18-38
18.3.14 RIICnDRT — I2C Bus Transmit Data Register....18-41
18.3.15 RIICnDRR — I2C Bus Receive Data Register....18-42
18.3.16 RIICnDRS — I2C Bus Shift Register....18-43
18.4 Interrupt Sources....18-44
18.5 Operation....18-45
18.5.1 Communication Data Format....18-45
18.5.2 Initial Settings....18-46
18.5.3 Master Transmit Operation....18-47
18.5.4 Master Receive Operation....18-52
18.5.5 Slave Transmit Operation....18-58
18.5.6 Slave Receive Operation....18-61
18.6 SCL Synchronization Circuit....18-64
18.7 Facility for Delaying SDA Output....18-65
18.8 Digital Noise-Filter Circuits....18-66

18.9 Address Match Detection 18-67
18.9.1 Slave-Address Match Detection 18-67
18.9.2 Detection of the General Call Address 18-69
18.9.3 Device-ID Address Detection 18-70
18.9.4 Host Address Detection 18-72
18.10 Automatically Low-Hold Function for SCL 18-73
18.10.1 Function to Prevent Wrong Transmission of Transmit Data 18-73
18.10.2 NACK Reception Transfer Suspension Function 18-74
18.10.3 Function to Prevent Failure to Receive Data 18-75
18.11 Arbitration-Lost Detection Functions 18-77
18.11.1 Master Arbitration-Lost Detection (MALE Bit) 18-77
18.11.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit) 18-79
18.11.3 Slave Arbitration-Lost Detection (SALE Bit) 18-80
18.12 Start Condition/Restart Condition/Stop Condition Issuing Function 18-81
18.12.1 Issuing a Start Condition 18-81
18.12.2 Issuing a Restart Condition 18-81
18.12.3 Issuing a Stop Condition 18-83
18.13 Bus Hanging 18-84
18.13.1 Timeout Function 18-84
18.13.2 Extra SCL Clock Cycle Output Function 18-86
18.13.3 RIIC Reset and Internal Reset 18-87
18.14 SMBus Operation 18-88
18.14.1 SMBus Timeout Measurement 18-88
18.14.2 SMBus Host Notification Protocol/Notify ARP Master 18-89
18.15 Reset Function of RIIC 18-90
19. Serial Sound Interface 19-1
19.1 Features 19-1
19.2 Input/Output Pins 19-3
19.3 Register Description 19-4
19.3.1 Control Register (SSICR) 19-6
19.3.2 Status Register (SSISR) 19-10
19.3.3 Transmit Data Register (SSITDR) 19-12
19.3.4 Receive Data Register (SSIRDR) 19-12
19.3.5 FIFO Control Register (SSIFCR) 19-13
19.3.6 FIFO Status Register (SSIFSR) 19-15
19.3.7 Transmit FIFO Data Register (SSIFTDR) 19-17
19.3.8 Receive FIFO Data Register (SSIFRDR) 19-17
19.3.9 TDM Mode Register (SSITDMR) 19-18
19.3.10 FC Control Register (SSIFCCR) 19-19
19.3.11 FC Mode Register (SSIFCMR) 19-20
19.3.12 FC Status Register (SSIFCSR) 19-21

19.4 Operation Description 19-22
19.4.1 Bus Format 19-22
19.4.2 Non-Compressed Modes 19-23
19.4.3 TDM Mode 19-31
19.4.4 WS Continue Mode 19-32
19.4.5 Operation Modes 19-32
19.4.6 Transmit Operation 19-33
19.4.7 Receive Operation 19-36
19.4.8 Serial Bit Clock Control 19-38
19.5 Usage Notes 19-39
19.5.1 Limitations from Underflow or Overflow during DMA Operation 19-39
19.5.2 Note on Changing Mode from Master Transceiver to Master Receiver 19-39
19.5.3 Limits on TDM mode and WS Continue Mode 19-39
20. Media Local Bus 20-1
20.1 Features 20-1
20.2 Input/Output Pins 20-2
20.3 Register Description 20-2
21. CAN Interface 21-1
21.1 Overview 21-1
21.1.1 Units 21-1
21.1.2 Register addresses 21-2
21.1.3 Clock supply 21-2
21.1.4 Interrupts 21-3
21.1.5 I/O signals 21-3
21.2 Function 21-4
21.2.1 Block Diagram 21-6
21.3 Registers 21-7
21.3.1 RSCAN0CmCFG — Channel Configuration Register (m = 0 or 1) 21-20
21.3.2 RSCAN0CmCTR — Channel Control Register (m = 0 or 1) 21-22
21.3.3 RSCAN0CmSTS — Channel Status Register (m = 0 or 1) 21-26
21.3.4 RSCAN0CmERFL — Channel Error Flag Register (m = 0 or 1) 21-28
21.3.5 RSCAN0GCFG — Global Configuration Register 21-32
21.3.6 RSCAN0GCTR — Global Control Register 21-35
21.3.7 RSCAN0GSTS — Global Status Register 21-37
21.3.8 RSCAN0GERFL — Global Error Flag Register 21-39
21.3.9 RSCAN0GTINTSTS0 — Global TX Interrupt Status Register 0 21-40
21.3.10 RSCAN0GTSC — Global Timestamp Counter Register 21-42
21.3.11 RSCAN0GAFLECTR — Receive Rule Entry Control Register 21-43
21.3.12 RSCAN0GAFLCFG0 — Receive Rule Configuration Register 0 21-44
21.3.13 RSCAN0GAFLIDj — Receive Rule ID Register (j = 0 to 15) 21-45
21.3.14 RSCAN0GAFLMj — Receive Rule Mask Register (j = 0 to 15) 21-47

21.3.15 RSCAN0GAFLP0j — Receive Rule Pointer 0 Register (j = 0 to 15) 21-48
21.3.16 RSCAN0GAFLP1j — Receive Rule Pointer 1 Register (j = 0 to 15) 21-50
21.3.17 RSCAN0RMNB — Receive Buffer Number Register 21-51
21.3.18 RSCAN0RMNDy — Receive Buffer New Data Register y (y = 0) 21-52
21.3.19 RSCAN0RMIDq — Receive Buffer ID Register (q = 0 to 31) 21-53
21.3.20 RSCAN0RMPTRq — Receive Buffer Pointer Register (q = 0 to 31) 21-54
21.3.21 RSCAN0RMDF0q — Receive Buffer Data Field 0 Register (q = 0 to 31) 21-55
21.3.22 RSCAN0RMDF1q — Receive Buffer Data Field 1 Register (q = 0 to 31) 21-56
21.3.23 RSCAN0RFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7) 21-57
21.3.24 RSCAN0RFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7) 21-59
21.3.25 RSCAN0RFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7) 21-61
21.3.26 RSCAN0RFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7) 21-62
21.3.27 RSCAN0RFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7) 21-63
21.3.28 RSCAN0RFDF0x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7) 21-64
21.3.29 RSCAN0RFDF1x — Receive FIFO Buffer Access Data Field 1 Register (x = 0 to 7) 21-65
21.3.30 RSCAN0CFCCk — Transmit/receive FIFO buffer Configuration and Control Register k (k = 0 to 5) 21-66
21.3.31 RSCAN0CFSTSk — Transmit/receive FIFO buffer Status Register (k = 0 to 5) 21-70
21.3.32 RSCAN0CFPCTRk — Transmit/receive FIFO buffer Pointer Control Register (k = 0 to 5) 21-73
21.3.33 RSCAN0CFIDk — Transmit/receive FIFO buffer Access ID Register (k = 0 to 5) 21-75
21.3.34 RSCAN0CFPTRk — Transmit/receive FIFO buffer Access Pointer Register (k = 0 to 5) 21-77
21.3.35 RSCAN0CFDF0k — Transmit/receive FIFO buffer Access Data Field 0 Register (k = 0 to 5) 21-79
21.3.36 RSCAN0CFDF1k — Transmit/receive FIFO buffer Access Data Field 1 Register (k = 0 to 5) 21-80
21.3.37 RSCAN0FESTS — FIFO Empty Status Register 21-81
21.3.38 RSCAN0FFSTS — FIFO Full Status Register 21-82
21.3.39 RSCAN0FMSTS — FIFO Message Lost Status Register 21-83
21.3.40 RSCAN0RFISTS — Receive FIFO Buffer Interrupt Flag Status Register 21-84
21.3.41 RSCAN0CFRISTS — Transmit/receive FIFO buffer Receive Interrupt Flag Status Register 21-85
21.3.42 RSCAN0CFTISTS — Transmit/receive FIFO buffer Transmit Interrupt Flag Status Register 21-86
21.3.43 RSCAN0TMCp — Transmit Buffer Control Register (p = 0 to 31) 21-87
21.3.44 RSCAN0TMSTSp — Transmit Buffer Status Register (p = 0 to 31) 21-89
21.3.45 RSCAN0TMTRSTSy — Transmit Buffer Transmit Request Status Register y (y = 0) 21-91

21.3.46 RSCAN0TMTARSTSy — Transmit Buffer Transmit Abort Request Status Register y (y = 0) 21-92
21.3.47 RSCAN0TMTCSTSy — Transmit Buffer Transmit Complete Status Register y (y = 0) 21-93
21.3.48 RSCAN0TMTASTSy — Transmit Buffer Transmit Abort Status Register y (y = 0) 21-94
21.3.49 RSCAN0TMIECy — Transmit Buffer Interrupt Enable Configuration Register y (y = 0) 21-95
21.3.50 RSCAN0TMIDp — Transmit Buffer ID Register (p = 0 to 31) 21-96
21.3.51 RSCAN0TMPTRp — Transmit Buffer Pointer Register (p= 0 to 31) 21-97
21.3.52 RSCAN0TMDF0p — Transmit Buffer Data Field 0 Register (p = 0 to 31) 21-98
21.3.53 RSCAN0TMDF1p — Transmit Buffer Data Field 1 Register (p = 0 to 31) 21-99
21.3.54 RSCAN0TXQCCm — Transmit Queue Configuration and Control Register (m = 0 or 1) 21-100
21.3.55 RSCAN0TXQSTSm — Transmit Queue Status Register (m = 0 or 1) 21-102
21.3.56 RSCAN0TXQPCTRm — Transmit Queue Pointer Control Register (m = 0 or 1) 21-104
21.3.57 RSCAN0THLCCm — Transmit History Configuration and Control Register (m = 0 or 1) 21-105
21.3.58 RSCAN0THLSTSm — Transmit History Status Register (m = 0 or 1) 21-107
21.3.59 RSCAN0THLACCm — Transmit History Access Register (m = 0 or 1) 21-109
21.3.60 RSCAN0THLPCTRm — Transmit History Pointer Control Register (m = 0 or 1) 21-110
21.3.61 RSCAN0GTSTCFG — Global Test Configuration Register 21-111
21.3.62 RSCAN0GTSTCTR — Global Test Control Register 21-112
21.3.63 RSCAN0GLOCKK — Global Lock Key Register 21-113
21.4 Interrupt Sources 21-114
21.5 RSCAN Modes 21-118
21.5.1 Global Modes 21-118
21.5.2 Channel Modes 21-121
21.6 Reception Function 21-126
21.6.1 Data Processing Using the Receive Rule Table 21-126
21.7 Transmission Functions 21-130
21.7.1 Transmit Priority Determination 21-131
21.7.2 Transmission Using Transmit Buffers 21-131
21.7.3 Transmission Using FIFO Buffers 21-132
21.7.4 Transmission Using Transmit Queues 21-135
21.7.5 Transmit History Function 21-135
21.8 Gateway Function 21-137
21.9 Test Function 21-138
21.9.1 Standard Test Mode 21-138
21.9.2 Listen-Only Mode 21-138
21.9.3 Self-Test Mode (Loopback Mode) 21-139
21.9.4 Inter-Channel Communication Test 21-141

21.10 RS-CAN Setting Procedure 21-142
21.10.1 Initial Settings 21-142
21.10.2 Reception Procedure 21-148
21.10.3 Transmission Procedure 21-153
21.10.4 Test Settings 21-162

23.7.1 Control Register (CTRL) 23-6
23.7.2 Status Register (STAT) 23-9
23.7.3 Transmitter Channel 1 Audio Register (TLCA) 23-11
23.7.4 Transmitter Channel 2 Audio Register (TRCA) 23-12
23.7.5 Transmitter DMA Audio Data Register (TDAD) 23-12
23.7.6 Transmitter User Data Register (TUI) 23-13
23.7.7 Transmitter Channel 1 Status Register (TLCS) 23-14
23.7.8 Transmitter Channel 2 Status Register (TRCS) 23-15
23.7.9 Receiver Channel 1 Audio Register (RLCA) 23-16
23.7.10 Receiver Channel 2 Audio Register (RRCA) 23-16
23.7.11 Receiver DMA Audio Data (RDAD) 23-17
23.7.12 Receiver User Data Register (RUI) 23-18
23.7.13 Receiver Channel 1 Status Register (RLCS) 23-19
23.7.14 Receiver Channel 2 Status Register (RRCS) 23-20
23.8 Functional Description—Transmitter 23-21
23.8.1 Transmitter Module 23-21
23.8.2 Transmitter Module Initialization 23-21
23.8.3 Initial Settings for Transmitter Module 23-22
23.8.4 Transmitter Module Data Transfer 23-22
23.9 Functional Description—Receiver 23-24
23.9.1 Receiver Module 23-24
23.9.2 Receiver Module Initialization 23-24
23.9.3 Receiver Module Data Transfer 23-25
23.10 Disabling the Module 23-27
23.10.1 Transmitter and Receiver Idle 23-27
23.11 Compressed Mode Data 23-27
23.12 References 23-27
23.13 Usage Notes 23-28

23.13.1 Clearing TUIR 23-28
23.13.2 Frequency of Clock Input for Audio 23-28
24. CD-ROM Decoder 24-1
24.1 Features 24-1
24.1.1 Formats Supported by CD-ROM Decoder 24-2
24.2 Block Diagrams 24-2
24.3 Register Descriptions 24-5
24.3.1 Enable Control Register (CROMEN) 24-7
24.3.2 Sync Code-Based Synchronization Control Register (CROMSY0) 24-8
24.3.3 Decoding Mode Control Register (CROMCTL0) 24-9
24.3.4 EDC/ECC Check Control Register (CROMCTL1) 24-10
24.3.5 Automatic Decoding Stop Control Register (CROMCTL3) 24-11
24.3.6 Decoding Option Setting Control Register (CROMCTL4) 24-12
24.3.7 HEAD20 to HEAD22 Representation Control Register (CROMCTL5) 24-13
24.3.8 Sync Code Status Register (CROMST0) 24-13
24.3.9 Post-ECC Header Error Status Register (CROMST1) 24-14
24.3.10 Post-ECC Subheader Error Status Register (CROMST3) 24-14
24.3.11 Header/Subheader Validity Check Status Register (CROMST4) 24-15
24.3.12 Mode Determination and Link Sector Detection Status Register (CROMST5) 24-16
24.3.13 ECC/EDC Error Status Register (CROMST6) 24-17
24.3.14 Buffer Status Register (CBUFST0) 24-17
24.3.15 Decoding Stoppage Source Status Register (CBUFST1) 24-18
24.3.16 Buffer Overflow Status Register (CBUFST2) 24-18
24.3.17 Pre-ECC Correction Header: Minutes Data Register (HEAD00) 24-19
24.3.18 Pre-ECC Correction Header: Seconds Data Register (HEAD01) 24-19
24.3.19 Pre-ECC Correction Header: Frames (1/75 Second) Data Register (HEAD02) 24-19
24.3.20 Pre-ECC Correction Header: Mode Data Register (HEAD03) 24-19
24.3.21 Pre-ECC Correction Subheader: File Number (Byte 16) Data Register (SHEAD00) 24-20
24.3.22 Pre-ECC Correction Subheader: Channel Number (Byte 17) Data Register (SHEAD01) 24-20
24.3.23 Pre-ECC Correction Subheader: Sub-Mode (Byte 18) Data Register (SHEAD02) 24-20
24.3.24 Pre-ECC Correction Subheader: Data Type (Byte 19) Data Register (SHEAD03) 24-21
24.3.25 Pre-ECC Correction Subheader: File Number (Byte 20) Data Register (SHEAD04) 24-21
24.3.26 Pre-ECC Correction Subheader: Channel Number (Byte 21) Data Register (SHEAD05) 24-21
24.3.27 Pre-ECC Correction Subheader: Sub-Mode (Byte 22) Data Register (SHEAD06) 24-22
24.3.28 Pre-ECC Correction Subheader: Data Type (Byte 23) Data Register (SHEAD07) 24-22
24.3.29 Post-ECC Correction Header: Minutes Data Register (HEAD20) 24-22
24.3.30 Post-ECC Correction Header: Seconds Data Register (HEAD21) 24-23
24.3.31 Post-ECC Correction Header: Frames (1/75 Second) Data Register (HEAD22) 24-23
24.3.32 Post-ECC Correction Header: Mode Data Register (HEAD23) 24-23
24.3.33 Post-ECC Correction Subheader: File Number (Byte 16) Data Register (SHEAD20) 24-24
24.3.34 Post-ECC Correction Subheader: Channel Number (Byte 17) Data Register (SHEAD21) 24-24

24.3.35 Post-ECC Correction Subheader: Sub-Mode (Byte 18) Data Register (SHEAD22) 24-24
24.3.36 Post-ECC Correction Subheader: Data Type (Byte 19) Data Register (SHEAD23) 24-25
24.3.37 Post-ECC Correction Subheader: File Number (Byte 20) Data Register (SHEAD24) 24-25
24.3.38 Post-ECC Correction Subheader: Channel Number (Byte 21) Data Register (SHEAD25) ... 24-25
24.3.39 Post-ECC Correction Subheader: Sub-Mode (Byte 22) Data Register (SHEAD26) 24-26
24.3.40 Post-ECC Correction Subheader: Data Type (Byte 23) Data Register (SHEAD27) 24-26
24.3.41 Automatic Buffering Setting Control Register (CBUFCTL0) 24-27
24.3.42 Automatic Buffering Start Sector Setting: Minutes Control Register (CBUFCTL1) 24-28
24.3.43 Automatic Buffering Start Sector Setting: Seconds Control Register (CBUFCTL2) 24-28
24.3.44 Automatic Buffering Start Sector Setting: Frames Control Register (CBUFCTL3) 24-28
24.3.45 ISY Interrupt Source Mask Control Register (CROMST0M) 24-29
24.3.46 CD-ROM Decoder Reset Control Register (ROMDECRST) 24-29
24.3.47 CD-ROM Decoder Reset Status Register (RSTSTAT) 24-30
24.3.48 Serial Sound Interface Data Control Register (SSI) 24-31
24.3.49 Interrupt Flag Register (INTHOLD) 24-32
24.3.50 Interrupt Source Mask Control Register (INHINT) 24-33
24.3.51 CD-ROM Decoder Stream Data Input Register (STRMDIN0) 24-33
24.3.52 CD-ROM Decoder Stream Data Input Register (STRMDIN2) 24-34
24.3.53 CD-ROM Decoder Stream Data Output Register (STRMDOUT0) 24-34
24.4 Operation 24-35
24.4.1 Endian Conversion for Data in the Input Stream 24-35
24.4.2 Sync Code Maintenance Function 24-36
24.4.3 Error Correction 24-38
24.4.4 Automatic Decoding Stop Function 24-39
24.4.5 Buffering Format 24-40
24.4.6 Target-Sector Buffering Function 24-41
24.5 Interrupt Sources 24-43
24.5.1 Interrupt and DMA Transfer Request Signals 24-43
24.5.2 Timing of Status Registers Updates 24-44
24.6 Usage Notes 24-45
24.6.1 Stopping and Resuming Buffering Alone during Decoding 24-45
24.6.2 Setting Sync Code Status Register (CROMST0) 24-45
24.6.3 Link Blocks 24-45
24.6.4 Stopping and Resuming CD-DSP Operation 24-45
24.6.5 Note on Clearing the IREADY Flag 24-46
24.6.6 Note on Stream Data Transfer (1) 24-46
24.6.7 Note on Stream Data Transfer (2) 24-46
24.6.8 Note on Software Reset 24-46

27.7.6 Influences on Absolute Precision 27-25
27.7.7 Usage Note on Port Pins 27-25
28. USB2.0 Host/Function Module 28-1
28.1 Features 28-1
28.2 Input/Output Pins 28-3
28.3 Register Descriptions 28-4
28.3.1 System Configuration Control Register (SYSCFG0) 28-10
28.3.2 CPU Bus Wait Setting Register (BUSWAIT) 28-12
28.3.3 System Configuration Status Register (SYSSTS0) 28-13
28.3.4 Device State Control Register 0 (DVSTCTR0) 28-14
28.3.5 Test Mode Register (TESTMODE) 28-17
28.3.6 DMAn-FIFO Bus Configuration Registers (D0FBCFG, D1FBCFG) 28-18
28.3.7 FIFO Port Registers (CFIFO, D0FIFO, D1FIFO) 28-20
28.3.8 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL) 28-22
28.3.9 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR) 28-26
28.3.10 Interrupt Enable Register 0 (INTENB0) 28-28
28.3.11 Interrupt Enable Register 1 (INTENB1) 28-29
28.3.12 BRDY Interrupt Enable Register (BRDYENB) 28-30
28.3.13 NRDY Interrupt Enable Register (NRDYENB) 28-31
28.3.14 BEMP Interrupt Enable Register (BEMPENB) 28-31
28.3.15 SOF Output Configuration Register (SOFCFG) 28-32
28.3.16 Interrupt Status Register 0 (INTSTS0) 28-33
28.3.17 Interrupt Status Register 1 (INTSTS1) 28-36
28.3.18 BRDY Interrupt Status Register (BRDYSTS) 28-38
28.3.19 NRDY Interrupt Status Register (NRDYSTS) 28-39
28.3.20 BEMP Interrupt Status Register (BEMPSTS) 28-39
28.3.21 Frame Number Register (FRMNUM) 28-40
28.3.22 μFrame Number Register (UFRMNUM) 28-41
28.3.23 USB Address Register (USBADDR) 28-41
28.3.24 USB Request Type Register (USBREQ) 28-42
28.3.25 USB Request Value Register (USBVAL) 28-43

28.3.26 USB Request Index Register (USBINDX) 28-43
28.3.27 USB Request Length Register (USBLENG) 28-44
28.3.28 DCP Configuration Register (DCPCFG) 28-44
28.3.29 DCP Maximum Packet Size Register (DCPMAXP) 28-47
28.3.30 DCP Control Register (DCPCTR) 28-48
28.3.31 Pipe Window Select Register (PIPESEL) 28-52
28.3.32 Pipe Configuration Register (PIPECFG) 28-53
28.3.33 Pipe Buffer Setting Register (PIPEBUF) 28-57
28.3.34 Pipe Maximum Packet Size Register (PIPEMAXP) 28-59
28.3.35 Pipe Timing Control Register (PIPEPERI) 28-60
28.3.36 PIPEn Control Registers (PIPEnCTR) (n = 1 to F) 28-61
28.3.37 PIPEn Transaction Counter Enable Registers (PIPEnTRE) (n = 1 to 5, 9, and A to F) 28-70
28.3.38 PIPEn Transaction Counter Registers (PIPEnTRN) (n = 1 to 5, 9, and A to F) 28-71
28.3.39 Device Address n Configuration Registers (DEVADDn) (n = 0 to 9, and A) 28-72
28.3.40 UTMI Suspend Mode Register (SUSPMODE) 28-73
28.3.41 D0FIFO Continuous Transfer Port Register n (D0FIFOBn)
D1FIFO Continuous Transfer Port Register n (D1FIFOBn) (n = 0 to 7) 28-74
28.4 Operation 28-75
28.4.1 System Control and Oscillation Control 28-75
28.4.2 Interrupt Functions 28-77
28.4.3 Pipe Control 28-89
28.4.4 FIFO Buffer Memory 28-95
28.4.5 FIFO Port Functions 28-97
28.4.6 Control Transfers (DCP) 28-100
28.4.7 Bulk Transfers (PIPE1 to PIPE5, PIPE9 to PIPE15) 28-102
28.4.8 Interrupt Transfers (PIPE6 to PIPE9, PIPE10) 28-104
28.4.9 Isochronous Transfers (PIPE1 and PIPE2) 28-105
28.4.10 SOF Interpolation Function 28-113
29. Video Display Controller 5 (1): Overview 29-1
29.1 Features 29-1
29.2 Block Diagram 29-3
29.3 Input/Output Pins 29-4
29.4 Clocks 29-4
29.5 Hsync and Vsync Signals 29-5
29.5.1 External Input Vsync 29-5
29.5.2 Free-Running Vsync 29-6
29.5.3 Usage Note on Changing Vsync Signal Selections 29-8
30. Video Display Controller 5 (2): Input Controller 30-1
30.1 Input Controller Functions 30-1
30.1.1 Overview of Functions 30-1
30.1.2 Updating Registers of External Signal Input Block and Sync Signal Adjustment Block 30-2

30.1.3 Controlling Input 30-2
30.1.4 Controlling Externally Input Video Signals 30-3
30.1.5 Selecting Clock Edge for Externally Input Signals 30-4
30.1.6 Externally Input Sync Signal Inversion Control 30-4
30.1.7 Bit Allocation of Externally Input Video Image Signals 30-5
30.1.8 Typical Signal Timing of BT601 Format 30-9
30.1.9 Typical Signal Timing of BT656 Format 30-12
30.1.10 SAV/EAV Code in BT656 Format 30-14
30.1.11 BT656 Progressive Format 30-17
30.1.12 BT656/BT601/YCbCr422 Format Setting 30-21
30.1.13 YCbCr444/RBG888/666/565 Input Timing 30-24
30.1.14 Field Differentiation and Vsync Signal Phase Adjustment 30-26
30.1.15 Vsync Signal Delay Adjustment in Line Units 30-27
30.1.16 Sync Signal Delay Adjustment 30-27
30.1.17 Horizontal Noise Reduction 30-28
30.1.18 Color Matrix 30-30
30.2 Register Descriptions 30-33
30.2.1 External Input Block Register Update Control Register (INP_UPDATE) 30-34
30.2.2 Input Select Control Register (INP_SEL_CNT) 30-35
30.2.3 External Input Sync Signal Control Register (INP_EXT_SYNC_CNT) 30-36
30.2.4 Vsync Signal Phase Adjustment Register (INP_VSYNC_PH_ADJ) 30-37
30.2.5 Sync Signal Delay Adjustment Register (INP_DLY_ADJ) 30-37
30.2.6 Image Quality Adjustment Block Register Update Control Register (IMGCNT_UPDATE) 30-38
30.2.7 NR Control Register 0 (IMGCNT_NR_CNT0) 30-39
30.2.8 NR Control Register 1 (IMGCNT_NR_CNT1) 30-40
30.2.9 Image Quality Adjustment Block Matrix Mode Register (IMGCNT_MTX_MODE) 30-41
30.2.10 Image Quality Adjustment Block Matrix YG Adjustment Register 0 (IMGCNT_MTX_YG_ADJ0) 30-41
30.2.11 Image Quality Adjustment Block Matrix YG Adjustment Register 1 (IMGCNT_MTX_YG_ADJ1) 30-42
30.2.12 Image Quality Adjustment Block Matrix CBB Adjustment Register 0 (IMGCNT_MTX_CBB_ADJ0) 30-42
30.2.13 Image Quality Adjustment Block Matrix CBB Adjustment Register 1 (IMGCNT_MTX_CBB_ADJ1) 30-43
30.2.14 Image Quality Adjustment Block Matrix CRR Adjustment Register 0 (IMGCNT_MTX_CRR_ADJ0) 30-44
30.2.15 Image Quality Adjustment Block Matrix CRR Adjustment Register 1 (IMGCNT_MTX_CRR_ADJ1) 30-45
30.3 Usage Methods 30-46
30.3.1 Input Format Adjustment Method 30-46
30.3.2 Usage Method of Conversion Color Matrix 30-48

31. Video Display Controller 5 (3): Scaler 31-1
31.1 Scaler 31-1
31.1.1 Overview of Functions 31-1
31.1.2 Register Control 31-2
31.1.3 Synchronization Control 31-3
31.1.4 Setting Angle of View 31-8
31.1.5 Scaling Settings 31-12
31.1.6 Horizontal Prefilter 31-14
31.1.7 Horizontal Scale-Down 31-14
31.1.8 Vertical Scale-Down 31-16
31.1.9 Horizontal Scale Up 31-18
31.1.10 Vertical Scale-Up 31-19
31.1.11 IP Conversion 31-21
31.1.12 Control of Interrupt on Specified Image Line before Scaling-down, and Reading of Current Image Line before Scaling-down 31-23
31.1.13 Trimming 31-24
31.1.14 Screen Synthesis 31-25
31.1.15 Selecting Format for Writing Video Image Signals to Frame Buffer 31-26
31.1.16 Horizontal Mirroring and Rotation 31-27
31.1.17 Writing to Frame Buffer 31-27
31.1.18 Selecting a Scaling-up Process or Graphics 0 Process 31-33
31.1.19 Selecting Field for Frame Buffer Reading 31-34
31.1.20 Pointer Buffer and Frame Buffer Reading Processing 31-35
31.2 Register Descriptions 31-37
31.2.1 SCL0 Register Update Control Register (SC0_SCL0_UPDATE) 31-39
31.2.2 Mask Control Register (SC0_SCL0_FRC1) 31-40
31.2.3 Missing Vsync Compensation Control Register (SC0_SCL0_FRC2) 31-40
31.2.4 Output Sync Select Register (SC0_SCL0_FRC3) 31-41
31.2.5 Free-Running Period Control Register (SC0_SCL0_FRC4) 31-42
31.2.6 Output Delay Control Register (SC0_SCL0_FRC5) 31-42
31.2.7 Full-Screen Vertical Size Register (SC0_SCL0_FRC6) 31-43
31.2.8 Full-Screen Horizontal Size Register (SC0_SCL0_FRC7) 31-44
31.2.9 Vsync Detection Register (SC0_SCL0_FRC9) 31-45
31.2.10 Status Monitor 0 Register (SC0_SCL0_MON0) 31-45
31.2.11 Interrupt Control Register (SC0_SCL0_INT) 31-46
31.2.12 Scaling-Down Control Register (SC0_SCL0_DS1) 31-46
31.2.13 Vertical Capture Size Register (SC0_SCL0_DS2) 31-47
31.2.14 Horizontal Capture Size Register (SC0_SCL0_DS3) 31-48
31.2.15 Horizontal Scale Down Register (SC0_SCL0_DS4) 31-49
31.2.16 Initial Vertical Phase Register (SC0_SCL0_DS5) 31-50
31.2.17 Vertical Scaling Register (SC0_SCL0_DS6) 31-51

31.2.18 Scaling-Down Control Block Output Size Register (SC0_SCL0_DS7) 31-52
31.2.19 Scaling-Up Control Register (SC0_SCL0_US1) 31-53
31.2.20 Output Image Vertical Size Register (SC0_SCL0_US2) 31-54
31.2.21 Output Image Horizontal Size Register (SC0_SCL0_US3) 31-55
31.2.22 Scaling-Up Control Block Input Size Register (SC0_SCL0_US4) 31-56
31.2.23 Horizontal Scale Up Register (SC0_SCL0_US5) 31-56
31.2.24 Horizontal Scale Up Initial Phase Register (SC0_SCL0_US6) 31-57
31.2.25 Trimming Register (SC0_SCL0_US7) 31-57
31.2.26 Frame Buffer Read Select Register (SC0_SCL0_US8) 31-58
31.2.27 Background Color Register (SC0_SCL0_OVR1) 31-58
31.2.28 SCL1 Register Update Control Register (SC0_SCL1_UPDATE) 31-59
31.2.29 Writing Mode Register (SC0_SCL1_WR1) 31-60
31.2.30 Write Address Register 1T (SC0_SCL1_WR2) 31-61
31.2.31 Write Address Register 2T (SC0_SCL1_WR3) 31-62
31.2.32 Write Address Register 3T (SC0_SCL1_WR4) 31-63
31.2.33 Frame Sub-Sampling Register (SC0_SCL1_WR5) 31-64
31.2.34 Bit Reduction Register (SC0_SCL1_WR6) 31-65
31.2.35 Write Detection Register (SC0_SCL1_WR7) 31-65
31.2.36 Write Address Register 1B (SC0_SCL1_WR8) 31-66
31.2.37 Write Address Register 2B (SC0_SCL1_WR9) 31-67
31.2.38 Write Address Register 3B (SC0_SCL1_WR10) 31-68
31.2.39 Write Detection Register B (SC0_SCL1_WR11) 31-68
31.2.40 Status Monitor 1 Register (SC0_SCL1_MON1) 31-69
31.2.41 Pointer Buffer 0 Register (SC0_SCL1_PBUF0) 31-69
31.2.42 Pointer Buffer 1 Register (SC0_SCL1_PBUF1) 31-70
31.2.43 Pointer Buffer 2 Register (SC0_SCL1_PBUF2) 31-70
31.2.44 Pointer Buffer 3 Register (SC0_SCL1_PBUF3) 31-71
31.2.45 Pointer Buffer and Field Information Register (SC0_SCL1_PBUF_FLD) 31-71
31.2.46 Pointer Buffer Control Register (SC0_SCL1_PBUF_CNT) 31-72
31.2.47 Graphics 0 Register Update Control Register (GR0_UPDATE) 31-73
31.2.48 Frame Buffer Read Control Register (Graphics 0) (GR0_FLM_RD) 31-73
31.2.49 Frame Buffer Control Register 1 (Graphics 0) (GR0_FLM1) 31-74
31.2.50 Frame Buffer Control Register 2 (Graphics 0) (GR0_FLM2) 31-75
31.2.51 Frame Buffer Control Register 3 (Graphics 0) (GR0_FLM3) 31-76
31.2.52 Frame Buffer Control Register 4 (Graphics 0) (GR0_FLM4) 31-77
31.2.53 Frame Buffer Control Register 5 (Graphics 0) (GR0_FLM5) 31-78
31.2.54 Frame Buffer Control Register 6 (Graphics 0) (GR0_FLM6) 31-79
31.2.55 Alpha Blending Control Register 1 (Graphics 0) (GR0_AB1) 31-81
31.2.56 Alpha Blending Control Register 2 (Graphics 0) (GR0_AB2) 31-82
31.2.57 Alpha Blending Control Register 3 (Graphics 0) (GR0_AB3) 31-82
31.2.58 Alpha Blending Control Register 7 (Graphics 0) (GR0_AB7) 31-83

31.2.59 Alpha Blending Control Register 8 (Graphics 0) (GR0_AB8) 31-84
31.2.60 Alpha Blending Control Register 9 (Graphics 0) (GR0_AB9) 31-84
31.2.61 Alpha Blending Control Register 10 (Graphics 0) (GR0_AB10) 31-85
31.2.62 Alpha Blending Control Register 11 (Graphics 0) (GR0_AB11) 31-86
31.2.63 Background Color Control Register (Graphics 0) (GR0_BASE) 31-86
31.2.64 CLUT Table Control Register (Graphics 0) (GR0_CLUT) 31-87
31.3 Usage Method 31-88
31.3.1 Scaling Setting Example for 525i Video Input and VGA-Size (640 x 480) Video Output 31-88
31.3.2 Scaling Setting Example for Graphics Display 31-91
31.3.3 Scaling Setting Example for Scaled-up Graphics Display 31-93
32. Video Display Controller 5 (4): Image Quality Improver 32-1
32.1 Image Quality Improver 32-1
32.1.1 Overview of Functions 32-1
32.1.2 Register Update Control 32-1
32.1.3 Black Stretch 32-2
32.1.4 Enhancer 32-3
32.1.5 Color Matrix 32-9
32.2 Register Description 32-11
32.2.1 Register Update Control Register in Image Quality Improver (ADJ0_UPDATE) 32-12
32.2.2 Black Stretch Register (ADJ0_BKSTR_SET) 32-13
32.2.3 Enhancer Timing Adjustment Register 1 (ADJ0_ENH_TIM1) 32-14
32.2.4 Enhancer Timing Adjustment Register 2 (ADJ0_ENH_TIM2) 32-14
32.2.5 Enhancer Timing Adjustment Register 3 (ADJ0_ENH_TIM3) 32-15
32.2.6 Enhancer Sharpness Register 1 (ADJ0_ENH_SHP1) 32-15
32.2.7 Enhancer Sharpness Register 2 (ADJ0_ENH_SHP2) 32-16
32.2.8 Enhancer Sharpness Register 3 (ADJ0_ENH_SHP3) 32-17
32.2.9 Enhancer Sharpness Register 4 (ADJ0_ENH_SHP4) 32-18
32.2.10 Enhancer Sharpness Register 5 (ADJ0_ENH_SHP5) 32-18
32.2.11 Enhancer Sharpness Register 6 (ADJ0_ENH_SHP6) 32-19
32.2.12 Enhancer LTI Register 1 (ADJ0_ENH_LTI1) 32-20
32.2.13 Enhancer LTI Register 2 (ADJ0_ENH_LTI2) 32-21
32.2.14 Matrix Mode Register in Image Quality Improver (ADJ0_MTX_MODE) 32-22
32.2.15 Matrix YG Control Register 0 in Image Quality Improver (ADJ0_MTX_YG_ADJ0) 32-22
32.2.16 Matrix YG Control Register 1 in Image Quality Improver (ADJ0_MTX_YG_ADJ1) 32-23
32.2.17 Matrix CBB Control Register 0 in Image Quality Improver (ADJ0_MTX_CBB_ADJ0) 32-24
32.2.18 Matrix CBB Control Register 1 in Image Quality Improver (ADJ0_MTX_CBB_ADJ1) 32-25
32.2.19 Matrix CRR Control Register 0 in Image Quality Improver (ADJ0_MTX_CRR_ADJ0) 32-26
32.2.20 Matrix CRR Control Register 1 in Image Quality Improver (ADJ0_MTX_CRR_ADJ1) 32-27
32.3 Usage Method 32-28
32.3.1 Black Stretch Usage Method 32-28
32.3.2 LTI Processing of Enhancer 32-28

32.3.3 Sharpness Processing of Enhancer 32-29
32.3.4 Setting Method for Color Matrix Data Conversion 32-30
33. Video Display Controller 5 (5): Image Synthesizer 33-1
33.1 Image Synthesizer 33-1
33.1.1 Overview of Functions 33-1
33.1.2 Graphics Data Read Control 33-2
33.1.3 Setting Graphics Display Area 33-12
33.1.4 Interrupt Generation at Specified Line 33-13
33.1.5 Formats of Frame Buffer Read Signals and Corresponding Alpha Blending Types 33-13
33.1.6 Display Selection 33-14
33.1.7 Background Color Display Processing 33-16
33.1.8 Lower-Layer Graphics Display Processing 33-16
33.1.9 Current Graphics Display Processing 33-16
33.1.10 Display with Alpha Blending in a Rectangular Area 33-17
33.1.11 RGB-Index Chroma-Key Processing 33-19
33.1.12 CLUT-Index Chroma-Key Processing 33-20
33.1.13 Display with Alpha Blending in One-Pixel Units 33-21
33.1.14 Alpha Blending Calculation 33-22
33.1.15 CLUT Table 33-22
33.1.16 Multiplication Processing with Current Alpha at Alpha Blending in Rectangular Area 33-23
33.1.17 Selection of Lower-Layer Graphics in VIN Synthesizer 33-23
33.2 Register Descriptions 33-24
33.2.1 Graphics 2 Register Update Control Register (GR2_UPDATE) 33-28
33.2.2 Frame Buffer Read Control Register (Graphics 2) (GR2_FLM_RD) 33-28
33.2.3 Frame Buffer Control Register 1 (Graphics 2) (GR2_FLM1) 33-29
33.2.4 Frame Buffer Control Register 2 (Graphics 2) (GR2_FLM2) 33-30
33.2.5 Frame Buffer Control Register 3 (Graphics 2) (GR2_FLM3) 33-30
33.2.6 Frame Buffer Control Register 4 (Graphics 2) (GR2_FLM4) 33-31
33.2.7 Frame Buffer Control Register 5 (Graphics 2) (GR2_FLM5) 33-31
33.2.8 Frame Buffer Control Register 6 (Graphics 2) (GR2_FLM6) 33-32
33.2.9 Alpha Blending Control Register 1 (Graphics 2) (GR2_AB1) 33-33
33.2.10 Alpha Blending Control Register 2 (Graphics 2) (GR2_AB2) 33-34
33.2.11 Alpha Blending Control Register 3 (Graphics 2) (GR2_AB3) 33-35
33.2.12 Alpha Blending Control Register 4 (Graphics 2) (GR2_AB4) 33-35
33.2.13 Alpha Blending Control Register 5 (Graphics 2) (GR2_AB5) 33-36
33.2.14 Alpha Blending Control Register 6 (Graphics 2) (GR2_AB6) 33-36
33.2.15 Alpha Blending Control Register 7 (Graphics 2) (GR2_AB7) 33-37
33.2.16 Alpha Blending Control Register 8 (Graphics 2) (GR2_AB8) 33-37
33.2.17 Alpha Blending Control Register 9 (Graphics 2) (GR2_AB9) 33-38
33.2.18 Alpha Blending Control Register 10 (Graphics 2) (GR2_AB10) 33-38
33.2.19 Alpha Blending Control Register 11 (Graphics 2) (GR2_AB11) 33-39

33.2.20 Background Color Control Register (Graphics 2) (GR2_BASE) 33-39
33.2.21 CLUT Table Control Register (Graphics 2) (GR2_CLUT) 33-40
33.2.22 Status Monitor Register (Graphics 2) (GR2_MON) 33-40
33.2.23 Graphics 3 Register Update Control Register (GR3_UPDATE) 33-41
33.2.24 Frame Buffer Read Control Register (Graphics 3) (GR3_FLM_RD) 33-41
33.2.25 Frame Buffer Control Register 1 (Graphics 3) (GR3_FLM1) 33-42
33.2.26 Frame Buffer Control Register 2 (Graphics 3) (GR3_FLM2) 33-43
33.2.27 Frame Buffer Control Register 3 (Graphics 3) (GR3_FLM3) 33-43
33.2.28 Frame Buffer Control Register 4 (Graphics 3) (GR3_FLM4) 33-44
33.2.29 Frame Buffer Control Register 5 (Graphics 3) (GR3_FLM5) 33-44
33.2.30 Frame Buffer Control Register 6 (Graphics 3) (GR3_FLM6) 33-45
33.2.31 Alpha Blending Control Register 1 (Graphics 3) (GR3_AB1) 33-46
33.2.32 Alpha Blending Control Register 2 (Graphics 3) (GR3_AB2) 33-47
33.2.33 Alpha Blending Control Register 3 (Graphics 3) (GR3_AB3) 33-47
33.2.34 Alpha Blending Control Register 4 (Graphics 3) (GR3_AB4) 33-48
33.2.35 Alpha Blending Control Register 5 (Graphics 3) (GR3_AB5) 33-48
33.2.36 Alpha Blending Control Register 6 (Graphics 3) (GR3_AB6) 33-49
33.2.37 Alpha Blending Control Register 7 (Graphics 3) (GR3_AB7) 33-49
33.2.38 Alpha Blending Control Register 8 (Graphics 3) (GR3_AB8) 33-50
33.2.39 Alpha Blending Control Register 9 (Graphics 3) (GR3_AB9) 33-50
33.2.40 Alpha Blending Control Register 10 (Graphics 3) (GR3_AB10) 33-51
33.2.41 Alpha Blending Control Register 11 (Graphics 3) (GR3_AB11) 33-51
33.2.42 Background Color Control Register (Graphics 3) (GR3_BASE) 33-52
33.2.43 CLUT Table and Interrupt Control Register (Graphics 3) (GR3_CLUT_INT) 33-52
33.2.44 Status Monitor Register (Graphics 3) (GR3_MON) 33-53
33.2.45 VIN Synthesizer Register Update Control Register (GR_VIN_UPDATE) 33-54
33.2.46 Alpha Blending Control Register 1 (VIN Synthesizer) (GR_VIN_AB1) 33-55
33.3 Usage Method 33-56
33.3.1 Mute Image 33-56
33.3.2 Alpha Blending in Rectangular Area 33-56
34. Video Display Controller 5 (7): Output Controller 34-1
34.1 Output Controller 34-1
34.1.1 Overview of Functions 34-1
34.1.2 Register Update Control 34-2
34.1.3 Route Selection 34-2

34.1.8 Output Format Conversion 34-10
34.1.9 LCD TCON 34-16

34.2 Register Descriptions 34-26
34.2.1 Register Update Control Register G in Gamma Correction Block (GAM_G_UPDATE) 34-30
34.2.2 Function Switch Register in Gamma Correction Block (GAM_SW) 34-31
34.2.3 Table Setting Register G1 to G16 in Gamma Correction Block (GAM_G_LUT1 to GAM_G_LUT16) 34-32
34.2.4 Area Setting Register G1 in Gamma Correction Block (GAM_G_AREA1) 34-34
34.2.5 Area Setting Register G2 in Gamma Correction Block (GAM_G_AREA2) 34-35
34.2.6 Area Setting Register G3 in Gamma Correction Block (GAM_G_AREA3) 34-36
34.2.7 Area Setting Register G4 in Gamma Correction Block (GAM_G_AREA4) 34-37
34.2.8 Area Setting Register G5 in Gamma Correction Block (GAM_G_AREA5) 34-38
34.2.9 Area Setting Register G6 in Gamma Correction Block (GAM_G_AREA6) 34-39
34.2.10 Area Setting Register G7 in Gamma Correction Block (GAM_G_AREA7) 34-40
34.2.11 Area Setting Register G8 in Gamma Correction Block (GAM_G_AREA8) 34-41
34.2.12 Register Update Control Register B in Gamma Correction Block (GAM_B_UPDATE) 34-42
34.2.13 Table Setting Register B1 to B16 in Gamma Correction Block (GAM_B_LUT1 to GAM_B_LUT16) 34-43
34.2.14 Area Setting Register B1 in Gamma Correction Block (GAM_B_AREA1) 34-45
34.2.15 Area Setting Register B2 in Gamma Correction Block (GAM_B_AREA2) 34-46
34.2.16 Area Setting Register B3 in Gamma Correction Block (GAM_B_AREA3) 34-47
34.2.17 Area Setting Register B4 in Gamma Correction Block (GAM_B_AREA4) 34-48
34.2.18 Area Setting Register B5 in Gamma Correction Block (GAM_B_AREA5) 34-49
34.2.19 Area Setting Register B6 in Gamma Correction Block (GAM_B_AREA6) 34-50
34.2.20 Area Setting Register B7 in Gamma Correction Block (GAM_B_AREA7) 34-51
34.2.21 Area Setting Register B8 in Gamma Correction Block (GAM_B_AREA8) 34-52
34.2.22 Register Update Control Register R in Gamma Correction Block (GAM_R_UPDATE) 34-53
34.2.23 Table Setting Register R1 to R16 in Gamma Correction Block (GAM_R_LUT1 to GAM_R_LUT16) 34-54
34.2.24 Area Setting Register R1 in Gamma Correction Block (GAM_R_AREA1) 34-56
34.2.25 Area Setting Register R2 in Gamma Correction Block (GAM_R_AREA2) 34-57
34.2.26 Area Setting Register R3 in Gamma Correction Block (GAM_R_AREA3) 34-58
34.2.27 Area Setting Register R4 in Gamma Correction Block (GAM_R_AREA4) 34-59
34.2.28 Area Setting Register R5 in Gamma Correction Block (GAM_R_AREA5) 34-60
34.2.29 Area Setting Register R6 in Gamma Correction Block (GAM_R_AREA6) 34-61
34.2.30 Area Setting Register R7 in Gamma Correction Block (GAM_R_AREA7) 34-62
34.2.31 Area Setting Register R8 in Gamma Correction Block (GAM_R_AREA8) 34-63
34.2.32 TCON Register Update Control Register (TCON_UPDATE) 34-64
34.2.33 TCON Reference Timing Setting Register (TCON_TIM) 34-64
34.2.34 TCON Vertical Timing Setting Register A1 (TCON_TIM_STVA1) 34-65
34.2.35 TCON Vertical Timing Setting Register A2 (TCON_TIM_STVA2) 34-66
34.2.36 TCON Vertical Timing Setting Register B1 (TCON_TIM_STVB1) 34-67
34.2.37 TCON Vertical Timing Setting Register B2 (TCON_TIM_STVB2) 34-68
34.2.38 TCON Horizontal Timing Setting Register STH1 (TCON_TIM_STH1) 34-69

34.2.39 TCON Horizontal Timing Setting Register STH2 (TCON_TIM_STH2) 34-70
34.2.40 TCON Horizontal Timing Setting Register STB1 (TCON_TIM_STB1) 34-71
34.2.41 TCON Horizontal Timing Setting Register STB2 (TCON_TIM_STB2) 34-72
34.2.42 TCON Horizontal Timing Setting Register CPV1 (TCON_TIM_CPV1) 34-73
34.2.43 TCON Horizontal Timing Setting Register CPV2 (TCON_TIM_CPV2) 34-74
34.2.44 TCON Horizontal Timing Setting Register POLA1 (TCON_TIM_POLA1) 34-75
34.2.45 TCON Horizontal Timing Setting Register POLA2 (TCON_TIM_POLA2) 34-76
34.2.46 TCON Horizontal Timing Setting Register POLB1 (TCON_TIM_POLB1) 34-77
34.2.47 TCON Horizontal Timing Setting Register POLB2 (TCON_TIM_POLB2) 34-78
34.2.48 TCON Data Enable Polarity Setting Register (TCON_TIM_DE) 34-79
34.2.49 Register Update Control Register in Output Controller (OUT_UPDATE) 34-79
34.2.50 Output Interface Register (OUT_SET) 34-80
34.2.51 Brightness (DC) Correction Register 1 (OUT_BRIGHT1) 34-81
34.2.52 Brightness (DC) Correction Register 2 (OUT_BRIGHT2) 34-82
34.2.53 Contrast (Gain) Correction Register (OUT_CONTRAST) 34-82
34.2.54 Panel Dither Register (OUT_PDTHA) 34-83
34.2.55 Output Phase Control Register (OUT_CLK_PHASE) 34-84
34.3 Usage Methods 34-85
34.3.1 Gamma Correction Adjustment Method 34-85
34.3.2 Dither Usage Method 34-85
34.3.3 Output Format Adjustment Method 34-86
35. Video Display Controller 5 (8):System Controller 35-1
35.1 System Controller 35-1
35.1.1 Overview of Functions 35-1
35.1.2 Interrupt Control 35-1
35.1.3 Panel Clock Control 35-4
35.1.4 CLUT Table Read Select Signal Status Flag 35-5
35.2 Register Descriptions 35-6
35.2.1 Interrupt Control Register 1 (SYSCNT_INT1) 35-7
35.2.2 Interrupt Control Register 2 (SYSCNT_INT2) 35-9
35.2.3 Interrupt Control Register 4 (SYSCNT_INT4) 35-10
35.2.4 Interrupt Control Register 5 (SYSCNT_INT5) 35-11
35.2.5 Panel Clock Control Register (SYSCNT_PANEL_CLK) 35-12
35.2.6 CLUT Table Read Select Signal Status Register (SYSCNT_CLUT) 35-13
36. Capture Engine Unit 36-1
36.1 Features of CEU 36-1
36.2 Functional Overview of CEU 36-2
36.3 Pin Configuration of CEU 36-3
36.4 Register Descriptions of CEU 36-4
36.4.1 Capture Start Register (CAPSR) 36-5
36.4.2 Capture Control Register (CAPCR) 36-9

36.4.3 Capture Interface Control Register (CAMCR) 36-12
36.4.4 Capture Interface Cycle Register (CMCYR) 36-16
36.4.5 Capture Interface Offset Register (CAMOR) 36-17
36.4.6 Capture Interface Width Register (CAPWR) 36-19
36.4.7 Capture Interface Input Format Register (CAIFR) 36-21
36.4.8 CEU Register Control Register (CRCNTR) 36-25
36.4.9 CEU Register Forcible Control Register (CRCMPR) 36-26
36.4.10 Capture Filter Control Register (CFLCR) 36-27
36.4.11 Capture Filter Size Clip Register (CFSZR) 36-29
36.4.12 Capture Destination Width Register (CDWDR) 36-31
36.4.13 Capture Data Address Y Register (CDAYR) 36-32
36.4.14 Capture Data Address C Register (CDACR) 36-33
36.4.15 Capture Data Bottom-Field Address Y Register (CDBYR) 36-35
36.4.16 Capture Data Bottom-Field Address C Register (CDBCR) 36-36
36.4.17 Capture Bundle Destination Size Register (CBDSR) 36-37
36.4.18 Capture Low-Pass Filter Control Register (CLFCR) 36-38
36.4.19 Firewall Operation Control Register (CFWCR) 36-39
36.4.20 Capture Data Output Control Register (CDOCR) 36-39
36.4.21 Capture Event Interrupt Enable Register (CEIER) 36-43
36.4.22 Capture Event Flag Clear Register (CETCR) 36-45
36.4.23 Capture Status Register (CSTSR) 36-49
36.4.24 Capture Data Size Register (CDSSR) 36-51
36.4.25 Capture Data Address Y Register 2 (CDAYR2) 36-52
36.4.26 Capture Data Address C Register 2 (CDACR2) 36-54
36.4.27 Capture Data Bottom-Field Address Y Register 2 (CDBYR2) 36-56
36.4.28 Capture Data Bottom-Field Address C Register 2 (CDBCR2) 36-57
36.5 Usage Notes for CEU 36-59
36.5.1 Conditions for Connection to an External Module 36-59
36.5.2 Restrictions on Input/Output Functions 36-60
36.5.3 Cooperation with Video Display Controller 5 36-60
36.5.4 Software Reset 36-60
37. SCUX 37-1
37.1 Features 37-1
37.2 Input/Output Pins 37-3
37.3 Register Descriptions 37-4
37.3.1 IPC0_n Initialization Register (IPCIR_IPC0_n) (n = 0, 1, 2, 3) 37-11
37.3.2 IPC0_n Pass Select Register (IPSLR_IPC0_n) (n = 0, 1, 2, 3) 37-11
37.3.3 OPC0_n Initialization Register (OPCIR_OPC0_n) (n = 0, 1, 2, 3) 37-12
37.3.4 OPC0_n Pass Select Register (OPSLR_OPC0_n) (n = 0, 1, 2, 3) 37-12
37.3.5 FFD0_n FIFO Download Initialization Register (FFDIR_FFD0_n) (n = 0, 1, 2, 3) 37-13
37.3.6 FFD0_n FIFO Download Audio Information Register (FDAIR_FFD0_n) (n = 0, 1, 2, 3) 37-13

37.3.7 FFD0_n FIFO Download Request Size Register (DRQSR_FFD0_n) (n = 0, 1, 2, 3) 37-14
37.3.8 FFD0_n FIFO Download Pass Register (FFDPR_FFD0_n) (n = 0, 1, 2, 3) 37-15
37.3.9 FFD0_n FIFO Download Boot Register (FFDBR_FFD0_n) (n = 0, 1, 2, 3) 37-15
37.3.10 FFD0_n FIFO Download Event Mask Register (DEVMR_FFD0_n) (n = 0, 1, 2, 3) 37-16
37.3.11 FFD0_n FIFO Download Event Clear Register (DEVCR_FFD0_n) (n = 0, 1, 2, 3) 37-17
37.3.12 FFU0_n FIFO Upload Initialization Register (FFUIR_FFU0_n) (n = 0, 1, 2, 3) 37-18
37.3.13 FFU0_n FIFO Upload Audio Information Register (FUAIR_FFU0_n) (n = 0, 1, 2, 3) 37-18
37.3.14 FFU0_n FIFO Upload Request Size Register (URQSR_FFU0_n) (n = 0, 1, 2, 3) 37-19
37.3.15 FFU0_n FIFO Upload Pass Register (FFUPR_FFU0_n) (n = 0, 1, 2, 3) 37-20
37.3.16 FFU0_n FIFO Upload Event Mask Register (UEVMR_FFU0_n) (n = 0, 1, 2, 3) 37-21
37.3.17 FFU0_n FIFO Upload Event Clear Register (UEVCR_FFU0_n) (n = 0, 1, 2, 3) 37-22
37.3.18 2SRC0_m Initialization Register p (SRCIRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-23
37.3.19 2SRC0_m Audio Information Register p (SADIRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-24
37.3.20 2SRC0_m Bypass Register p (SRCBRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-25
37.3.21 2SRC0_m IFS Control Register p (IFSCRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-25
37.3.22 2SRC0_m IFS Value Setting Register p (IFSVRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-26
37.3.23 2SRC0_m Control Register p (SRCCRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-31
37.3.24 2SRC0_m Minimum FS Setting Register p (MNFSRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-32
37.3.25 2SRC0_m Buffer Size Setting Register p (BFSSRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-32
37.3.26 2SRC0_m SCU2 Status Register p (SC2SRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-33
37.3.27 2SRC0_m Wait Time Setting Register p (WATSRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-33
37.3.28 2SRC0_m Event Mask Register p (SEVMRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-34
37.3.29 2SRC0_m Event Clear Register p (SEVCRp_2SRC0_m) (m = 0, 1; p = 0, 1) 37-35
37.3.30 2SRC0_m Initialization Register RIF (SRCIRR_2SRC0_m) (m = 0, 1) 37-36
37.3.31 DVU0_n Initialization Register (DVUIR_DVU0_n) (n = 0, 1, 2, 3) 37-36
37.3.32 DVU0_n Audio Information Register (VADIR_DVU0_n) (n = 0, 1, 2, 3) 37-37
37.3.33 DVU0_n Bypass Register (DVUBR_DVU0_n) (n = 0, 1, 2, 3) 37-38
37.3.34 DVU0_n Control Register (DVUCR_DVU0_n) (n = 0, 1, 2, 3) 37-38
37.3.35 DVU0_n Zero Cross Mute Control Register (ZCMCR_DVU0_n) (n = 0, 1, 2, 3) 37-39
37.3.36 DVU0_n Volume Ramp Control Register (VRCTR_DVU0_n) (n = 0, 1, 2, 3) 37-40
37.3.37 DVU0_n Volume Ramp Period Register (VRPDR_DVU0_n) (n = 0, 1, 2, 3) 37-41
37.3.38 DVU0_n Volume Ramp Decibel Register (VRDBR_DVU0_n) (n = 0, 1, 2, 3) 37-42
37.3.39 DVU0_n Volume Ramp Wait Time Register (VRWTR_DVU0_n) (n = 0, 1, 2, 3) 37-43
37.3.40 DVU0_n Volume Value Setting 0 Register (VOL0R_DVU0_n) (n = 0, 1, 2, 3) 37-43
37.3.41 DVU0_n Volume Value Setting 1 Register (VOL1R_DVU0_n) (n = 0, 1, 2, 3) 37-44
37.3.42 DVU0_n Volume Value Setting 2 Register (VOL2R_DVU0_n) (n = 0, 1, 2, 3) 37-45
37.3.43 DVU0_n Volume Value Setting 3 Register (VOL3R_DVU0_n) (n = 0, 1, 2, 3) 37-46
37.3.44 DVU0_n Volume Value Setting 4 Register (VOL4R_DVU0_n) (n = 0, 1, 2, 3) 37-47
37.3.45 DVU0_n Volume Value Setting 5 Register (VOL5R_DVU0_n) (n = 0, 1, 2, 3) 37-48
37.3.46 DVU0_n Volume Value Setting 6 Register (VOL6R_DVU0_n) (n = 0, 1, 2, 3) 37-49
37.3.47 DVU0_n Volume Value Setting 7 Register (VOL7R_DVU0_n) (n = 0, 1, 2, 3) 37-50

37.3.48 DVU0_n Enable Register (DVUER_DVU0_n) (n = 0, 1, 2, 3) 37-50
37.3.49 DVU0_n Status Register (DVUSR_DVU0_n) (n = 0, 1, 2, 3) 37-51
37.3.50 DVU0_n Event Mask Register (VEVMR_DVU0_n) (n = 0, 1, 2, 3) 37-52
37.3.51 DVU0_n Event Clear Register (VEVCR_DVU0_n) (n = 0, 1, 2, 3) 37-54
37.3.52 MIX0_0 Initialization Register (MIXIR_MIX0_0) 37-55
37.3.53 MIX0_0 Audio Information Register (MADIR_MIX0_0) 37-56
37.3.54 MIX0_0 Bypass Register (MIXBR_MIX0_0) 37-57
37.3.55 MIX0_0 Mode Register (MIXMR_MIX0_0) 37-57
37.3.56 MIX0_0 Volume Period Register (MVPDR_MIX0_0) 37-58
37.3.57 MIX0_0 Decibel A Register (MDBAR_MIX0_0) 37-59
37.3.58 MIX0_0 Decibel B Register (MDBBR_MIX0_0) 37-60
37.3.59 MIX0_0 Decibel C Register (MDBCR_MIX0_0) 37-61
37.3.60 MIX0_0 Decibel D Register (MDBDR_MIX0_0) 37-62
37.3.61 MIX0_0 Decibel Enable Register (MDBER_MIX0_0) 37-63
37.3.62 MIX0_0 Status Register (MIXSR_MIX0_0) 37-63
37.3.63 Software Reset Register (SWRSR_CIM) 37-64
37.3.64 DMA Control Register (DMACR_CIM) 37-65
37.3.65 DMA Transfer Register for FFD0_n (DMATDn_CIM) (n = 0, 1, 2, 3) 37-66
37.3.66 DMA Transfer Register for FFU0_n (DMATUn_CIM) (n = 0, 1, 2, 3) 37-67
37.3.67 SSI Route Select Register (SSIRSEL_CIM) 37-68
37.3.68 FFD0_n Timing Select Register (FDTSELn_CIM) (n = 0, 1, 2, 3) 37-70
37.3.69 FFU0_n Timing Select Register (FDTSELn_CIM) (n = 0, 1, 2, 3) 37-72
37.3.70 SSI Pin Mode Register (SSIPMD_CIM) 37-74
37.3.71 SSI Control Register (SSICTRL_CIM) 37-76
37.3.72 SRCn Route Select Register (SRCRSELn_CIM) (n = 0, 1, 2, 3) 37-78
37.3.73 MIX Route Select Register (MIXRSEL_CIM) 37-82
37.4 Operation 37-86
37.4.1 Initial Setting Procedure 37-86
37.4.2 Transfer Start Procedure and Stop Procedure 37-86
37.4.3 Data Rearrangement for Each Channel 37-91
37.4.4 Pin Connection Specifications of SSIF 37-94
37.4.5 Data Transfer Route 37-95
37.4.6 Input Timing Signal and Output Timing Signal 37-101
37.4.7 2SRC (SRC) Block 37-104
37.4.8 DVU Block 37-106
37.4.9 MIX Block 37-110

1. Overview

1.1 Features of This LSI

This LSI is a single-chip microcontroller that includes an Arm Cortex®-A9 processor along with the integrated peripheral functions required to configure a system.

This LSI includes a 32-Kbyte L1 instruction cache, a 32-Kbyte L1 data cache, and a 128-Kbyte L2 cache. This LSI also includes on-chip peripheral functions necessary for system configuration, such as a 3-Mbyte (RZ/A1L and RZ/A1LU) or 2-Mbyte (RZ/A1LC) large-capacity RAM (128 Kbytes are shared by the data-retention RAM), data-retention RAM, multi-function timer pulse unit 2, OS timer, realtime clock, serial communication interface with FIFO, serial communication interface, I^2C bus interface, serial sound interface, media local bus (RZ/A1L only), SCUX, CAN interface, IEBus™* controller (RZ/A1L only), Renesas SPDIF interface, Renesas serial peripheral interface, SPI multi I/O bus controller, CD-ROM decoder (RZ/A1L only), A/D converter, LIN interface (RZ/A1L only), Ethernet controller, EthernetAVB (RZ/A1LU only), USB 2.0 host/function, video display controller 5, JPEG codec unit (RZ/A1LU only), capture engine unit, SD host interface, MMC host interface, interrupt controller modules, and general I/O ports.

The features of this LSI are listed in Table 1.1.

Note: * IEBus (Inter Equipment Bus) is a trademark of Renesas Electronics Corporation.

Table 1.1 Features of RZ/A1L, RZ/A1LU, and RZ/A1LC

Items	Specification
CPU	• Arm Cortex-A9 processor • Maximum operating frequency: 400 MHz • Instruction cache size: 32 Kbytes • Data cache size: 32 Kbytes (write-back algorithm) • TLB entries: 128 entries • Jazelle® architecture extension: Full implementation • Media processing engine with NEON™ technology
L2 cache memory	• Arm CoreLink™ Level 2 Cache Controller L2C-310 • Operating frequency: 133 MHz • Cache size: 128 Kbytes
Interrupt controller	• Arm PrimeCell® Generic Interrupt Controller (PL390) • External interrupt pins (NMI, IRQ7 to IRQ0, and TINT121 to TINT0) • On-chip peripheral interrupts: Priority level set for each module • 32 priority levels available
Bus state controller	• Address space divided into six areas (0 to 5), each a maximum of 64 Mbytes • The following features settable for each area independently —Bus size (8, 16, or 32 bits): Available sizes depend on the area. —Number of access wait cycles (different wait cycles can be specified for read and write access cycles in some areas) —Idle wait cycle insertion (between the same area access cycles or different area access cycles) —Specifying the memory to be connected to each area enables direct connection to SRAM, SRAM with byte selection, SDRAM, and burst ROM (clocked synchronous or asynchronous). The address/data multiplexed I/O (MPX) interface is also available. • Outputs a chip select signal ($\overline{CS0}$ to $\overline{CS5}$) according to the target area ($\overline{CS}$ assert or negate timing can be selected by software) • SDRAM refresh Auto refresh or self refresh mode selectable • SDRAM burst access
Direct memory access controller	• Sixteen channels; external requests are available for one of them. • Can be activated by on-chip peripheral modules. • A specific DMA transfer interval can be specified to adjust the bus occupancy. • Link mode (DMA transfer under descriptor control) supported • Transfer information can be automatically reloaded.
Clock pulse generator	• Clock mode: Input clock can be selected from external input (EXTAL or USB_X1) or crystal resonator. • Input clock can be multiplied by 32 (max.) by the internal PLL circuit. • Peak values of EMI noise can be reduced by the on-chip SSCG circuit. • Five types of clocks generated: —CPU clock (Iφ): Maximum 400.00 MHz —Internal bus clock (Bφ): Maximum 133.33 MHz —Peripheral clock 1 (P1φ): Maximum 66.67 MHz —Peripheral clock 0 (P0φ): Maximum 33.33 MHz
Watchdog timer	• On-chip one-channel watchdog timer • A counter overflow can reset the LSI.
Power-down modes	• Four power-down modes provided to reduce the power consumption in this LSI —Sleep mode —Software standby mode —Deep standby mode —Module standby mode

Items	Specification
Multi-function timer pulse unit 2	• Maximum 16 lines of pulse inputs/outputs based on five channels of 16-bit timers • 18 output compare and input capture registers • Input capture function • Pulse output modes Toggle, PWM, complementary PWM, and reset-synchronized PWM modes • Synchronization of multiple counters • Complementary PWM output mode —Non-overlapping waveforms output for 3-phase inverter control —Automatic dead time setting —0% to 100% PWM duty value specifiable —A/D converter start request delaying function —Interrupt skipping at crest or trough • Reset-synchronized PWM mode Three-phase PWM waveforms in positive and negative phases can be output with a required duty value. • Phase counting mode Two-phase encoder pulse counting available
OS timer	• Two-channel 32-bit counters • Two operating modes: —Interval timer mode —Free-running comparison mode • DMA transfer request or interrupt request can be issued when a compare match occurs.
Realtime clock	• Internal clock, calendar function, alarm function • Interrupts can be generated at intervals of 1/64 s by the 32.768-kHz on-chip crystal oscillator.
Serial communication interface with FIFO	• Five channels • Clock synchronous mode or asynchronous mode selectable • Simultaneous transmission and reception (full-duplex communication) supported • Dedicated baud rate generator • Separate 16-byte FIFO registers for transmission and reception • Modem control function (channels 0 to 2 in asynchronous mode)
Serial communication interface	• Two channels • Clock synchronous mode, asynchronous mode, or smart card interface mode is selectable. • Simultaneous transmission and reception (full-duplex communication) supported • Dedicated baud rate generator • LSB first/MSB first selectable • Modem control function • Encoding and decoding of IrDA communications waveforms in accord with version 1.0 of the IrDA standard (on channel 0)
Renesas serial peripheral interface	• Three channels • SPI operation • Master mode and slave mode selectable • Programmable bit length, clock polarity, and clock phase can be selected. • Consecutive transfers • MSB first/LSB first selectable • Maximum transfer rate: 33.33 Mbps
SPI multi I/O bus controller	• One channel • Up to two serial flash memories with multiple I/O bus sizes (single/dual/quad) can be connected. • External address space read mode (built-in read cache) • SPI operating mode • Clock polarity and clock phase can be selected. • MSB first/LSB first selectable • Maximum transfer rate: 533.33Mbps (SDR transfer, with two serial flash memories connected) 1066.66Mbps (DDR transfer, with two serial flash memories connected) (RZ/A1LU only)
I^2C bus interface	• Four channels • Master mode and slave mode supported • Support for 7-bit and 10-bit slave address formats • Support for multi-master operation • Timeout detection

Items	Specification
Serial sound interface	• Four-channel bidirectional serial transfer • Duplex communication (channels 0, 1, and 3) • Support of various serial audio formats • Support of master and slave functions • Generation of programmable word clock and bit clock • Multi-channel formats • Support of 8, 16, 18, 20, 22, 24, and 32-bit data formats • Support of eight-stage FIFO for transmission and reception • Support of TDM mode • Support of WS continue mode in which the SSIWS signal is not stopped. • Support of direct transfer to the SCUX module • A change of the sampling frequency can be detected.
Media local bus (RZ/A1L only)	• Conforms with version 2.0 of the MediaLB standard. Data transfer at up to 50 Mbps is possible.
SCUX	• Sampling rate conversion —Asynchronous or synchronous sampling rate conversion is possible. —Sampling rate (synchronous mode) Note: The selectable sampling rates depend on the number of used channels and rate ratio. Input [kHz]: 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, 48, 64, 88.2, or 96 is selectable. Output [kHz]: 8, 16, 24, 44.1, 48, or 96 is selectable. —Sampling rate (asynchronous mode) Note: The selectable sampling rates depend on the number of used channels and rate ratio. Input/output [kHz]: 1 to 96 —Data format: 16 or 24 bits • Digital volume and mute functions —The digital volume can be set within the range from a multiple of 0 to 8 (−120 to 18 dB) —Volume ramping supports soft mute, fade-in, and fade-out. —The zero crossing mute function can apply muting at zero-crossing points. • Mixer —Data of two to four source systems can be mixed (added together) into one system. —The ratio to add the sources can be set. • Direct transfer to the serial sound interface module is supported.
CAN interface	• Two channels • ISO11898-1 compliant • Message buffer: —Up to 64 2-channel receive message buffers: shared among all channels. —16 transmit message buffers per channel
IEBus™ controller (RZ/A1L only)	• Conforms with the IEBus protocol (communication modes 1 and 2). • Transfer rates: approximately 18 kbps (in communication mode 1), approximately 27 kbps (in communication mode 2) • Maximum numbers of bytes for transfer: 32 bytes/frame (in communication mode 1), 128 bytes/frame (in communication mode 2) • Operating clock: 8 MHz Note: Input of peripheral clock 0 (P0φ) running at 32 MHz is required.
Renesas SPDIF interface	• Support of IEC60958 standard (stereo and consumer use modes only) • Sampling frequencies of 32 kHz, 44.1 kHz, and 48 kHz • Audio word sizes of 16 to 24 bits per sample • Biphase mark encoding • Double buffered data • Parity encoded serial data • Simultaneous transmit and receive • Receiver autodetects IEC 61937 compressed mode data.

Items	Specification
CD-ROM decoder (RZ/A1L only)	• Support of five formats: Mode 0, mode 1, mode 2, mode 2 form 1, and mode 2 form 2 • Sync codes detection and protection (Protection: When a sync code is not detected, it is automatically inserted.) • Descrambling • ECC correction —P, Q, PQ, and QP correction —PQ or QP correction can be repeated up to three times. • EDC check Performed before and after ECC • Mode and form are automatically detected. • Link sectors are automatically detected. • Buffering data control Buffering CD-ROM data including Sync code is transferred in specified format, after the data is descrambled, corrected by ECC, and checked by EDC.
LIN interface (RZ/A1L only)	• Conforms with revisions 1.3, 2.0, 2.1, and 2.2 of the LIN protocol and SAEJ 2062. • Master mode selectable
Ethernet controller	• Conforms with the Ethernet or the IEEE802.3 MAC (Media Access Control) layer standard • MAC function Constructs/deconstructs data frames (frame format conforming to IEEE802.3, 2000 Edition) Supports transfer at 10 and 100 Mbps Supports full-duplex mode Flow control conforming to IEEE802.3x Supports an MII (Media Independent Interface) for connection to a PHY interface in conformance with IEEE 802.3 Upward protocol support (checksum) function • E-DMAC (Direct Memory Access Controller for Ethernet controller) function
EthernetAVB (RZ/A1LU only)	• Conforms with the Ethernet or the IEEE802.3 MAC (Media Access Control) layer standard • MAC function Constructs/deconstructs data frames (frame format conforming to IEEE802.3, 2000 Edition) Supports transfer at 100 Mbps Supports full-duplex mode Flow control conforming to IEEE802.3x Supports an MII (Media Independent Interface) for connection to a PHY interface in conformance with IEEE 802.3 Upward protocol support (checksum) function • AVB-DMAC (DMAC dedicated to EthernetAVB) function AVB-DMAC conforms with the following 3 standards; IEEE802.1AS (Clock Synchronization Protocol), IEEE802.1Qav (Realtime Transfer Protocol) and IEEE802.1Qat (Bandwidth Reservation Protocol)
USB 2.0 host/function module	• Two channels • Conforms to the Universal Serial Bus Specification Revision 2.0 • 480-Mbps, 12-Mbps, and 1.5-Mbps transfer rates provided (host mode) • 480-Mbps and 12-Mbps transfer rates provided (function mode) • On-chip 8-Kbyte RAM as communication buffers
Video display controller 5	• Video input interface BT601, BT656 format (NTSC/PAL) input: Input clock: 27 MHz/54 MHz Digital pin input (channel 0): YCbCr422, YCbCr444, RGB888, RGB666, RGB565 Digital pin input size: Maximum input video image size to be set*: 1440 pixels × 1024 lines (horizontal × vertical) Note:*Depends on the AC characteristics of the connected device. Examples of input video image size : XGA (1024 × 768), SVGA (800 × 600), WVGA (800 × 480), VGA (640 × 480), WQVGA (480 × 240), QVGA (320 × 240, 240 × 320) • Input video control Horizontal noise reduction (NR) and brightness and gain adjustment using matrix operation

Items	Specification
Video display controller 5	• Scaling control Vertical and horizontal scaling up or down of input video possible at a desired ratio (scaling up of graphics also possible) Scaling up ratio: 1 to 8; scaling down ratio: 1/8 to 1 Interpolation: Hold or linear selectable 2D IP conversion: 2D IP conversion through separately setting the initial phases for the top and bottom fields • Video recording Output pixel format: YCbCr444, YCbCr422, RGB888, RGB565 Output field rate: 1/1, 1/2, 1/4, 1/8 Rotation: Horizontal mirroring and 90/180/270 degree rotation for YCbCr422 and RGB565 Maximum video image size to be stored: ×1 size of input video image • Output video control Black stretch: Black area stretched according to Y signal state Enhancer capability: LTI (transient improvement) and sharpness (contour emphasis) for Y signal • Three graphics layers (one of them also for input video) Available input pixel formats 1 bit/pixel: CLUT1 4 bits/pixel: CLUT4 8 bits/pixel: CLUT8 16 bits/pixel: YCbCr422 (graphics layers 0 and 1), RGB565, ARGB1555, RGBA5551, ARGB4444 32 bits/pixel: ARGB8888, RGBA8888, RGB888, YCbCr444 (graphics layer 0) • Superimposition Alpha blending in a rectangular area: Input video, layer 1, and layer 2 blended according to the transparency percentage α (fade-in and fade-out function available) Chroma key function: Mixing based on transparency percentage α using the specified RGB and CLUT value Pixel-base alpha blending: Alpha blending for each pixel based on transparency percentage α • Panel output control Panel output correction: Brightness adjustment and contrast adjustment, gamma correction, panel dithering TCON: Various timing output for LCD panel driving provided by a total of seven vertical and horizontal panel driver signals Panel output pixel format: RGB888, RGB666, RGB565, serial RGB Output video image size: Maximum output video image size to be set*: 1999 pixels × 2035 lines (horizontal × vertical) Note:*Depends on the AC characteristics of the display panel. Examples of output video image size: XGA (1024 × 768), SVGA (800 × 600), WVGA (800 × 480), VGA (640 × 480), WQVGA (480 × 240), QVGA (320 × 240, 240 × 320)
JPEG codec unit (RZ/A1LU only)	• Compression and decompression method conforming to the JPEG baseline standard within the range described in this document. • Operational precision: Conforming to JPEG Part 2, ISO-IEC10918-2 • Pixel format: Compression: YCbCr422 Decompression: YCbCr444, YCbCr422, YCbCr411, YCbCr420 Output pixel format to the buffer: YCbCr422, ARGB8888, RGB565 • Four quantization tables provided • Four Huffman tables provided (two tables for AC coefficients and two tables for DC coefficients) • Markers supported: SOI, SOF0, SOS, DQT, DHT, DRI, RSTm, and EOI • Image data rate: Max. 133.33 Mbytes/s (at 66.67-MHz operation)

Items	Specification
Capture engine unit	• Examples of input video image size : 5 megapixels (2,560 × 1,920), 3 megapixels (2,048 × 1,536), 2 megapixels (1,632 × 1,224), UXGA (1,600 × 1,200), SXGA (1) (1,280 × 1,024), SXGA (2) (1,280 × 960), WXGA (1,280 × 768), XGA (1,024 × 768), SVGA (800 × 600), WVGA (800 × 480), VGA (640 × 480), WQVGA (480 × 240), QVGA (320 × 240, 240 × 320) Note: Depends on the AC characteristics of the connected device, frame rate of the connected device, and transfer speed to the destination RAM. • Input format: 8-bit YCbCr422 binary data • Memory output format: YCbCr422, YCbCr420 Note: The captured data cannot be displayed via the video display controller 5 because the Y data and CbCr data are split when written to memory.
SD host interface	• Two channels • SD memory I/O card interface (1-/4-bit SD bus) • Error check function: CRC7 (command), CRC16 (data) • Interrupt requests —Card access interrupt —SDIO access interrupt —Card detect interrupt • DMA transfer requests —SD_BUF write —SD_BUF read • Card detection function, write protect supported
MMC host interface	• Interface to multi-media card (MMC) • Data bus: 1-/4-/8-bit MMC mode • Interrupt requests: card detection, error/time-out, and normal operation • DMA transfer requests: CE_DATA write and CE_DATA read • Card detection function
General I/O ports	• 176-pin QFP or BGA: 78 I/Os, 8 inputs with open-drain outputs, and 14 inputs (input only) • 208-pin QFP: 100 I/O pins, 8 input pins with open-drain outputs, and 14 inputs (input only) • Input or output can be selected for each bit.
A/D converter	• 12-bit resolution • Eight input channels • Minimum conversion time: 5.0 µs • A/D conversion request by the external trigger or timer trigger
Debugging interface	• Arm CoreSight™ architecture • JTAG-standard pin assignment
On-chip RAM	• 3-Mbyte (RZ/A1L and RZ/A1LU) or 2-Mbyte (RZ/A1LC) large capacity memory for video display/ recording and work (128 Kbytes are used for data retention) • 128-Kbyte memory for data retention (16 Kbytes × 2, 32 Kbytes × 1, 64 Kbytes × 1)
Boot modes	• Four boot modes Boot mode 0: Booting from memory (bus width: 16 bits) connected to CS0 area Boot mode 1: Booting from a serial flash memory Boot mode 2: Booting from a NAND flash memory with SD controller Boot mode 3: Booting from a NAND flash memory with MMC controller
Power supply voltage	• Vcc: 1.10 to 1.26 V • PVcc: 3.0 to 3.6 V

Items	Specification
Package	• PLBG0176KA-A 176-pin BGA, 8-mm square, 0.5-mm pitch JEITA package code: P-LFBGA176-8×8-0.50 RENESAS code: PLBG0176KA-A • PLQP0176KB-A 176-pin QFP, 24-mm square, 0.5-mm pitch JEITA package code: P-LFQFP176-24×24-0.50 RENESAS code: PLQP0176KB-A • PLQP0208KB-A 208-pin QFP, 28-mm square, 0.5-mm pitch JEITA package code: P-LFQFP208-28×28-0.50 RENESAS Code : PLQP0208KB-A • PRBG0233GA-A 233-pin BGA, 15-mm square, 0.8-mm pitch JEITA package code: P-FBGA233-15x15-0.80 RENESAS Code : PRBG0233GA-A

1.5 Pin Functions

Table 1.3 Pin Functions

Classification	Symbol	I/O	Name	Function
Power supply	Vcc	I	Power supply	Power supply pins. All the Vcc pins must be connected to the system power supply. This LSI does not operate correctly if there is a pin left open.
	Vss	I	Ground	Ground pins. All the Vss pins must be connected to the system power supply (0 V). This LSI does not operate correctly if there is a pin left open.
	PVcc	I	Power supply for I/O circuits	Power supply for I/O pins. All the PVcc pins must be connected to the system power supply. This LSI does not operate correctly if there is a pin left open.
	PLLVcc	I	Power supply for PLL	Power supply for the on-chip PLL oscillator.
Clock	EXTAL	I	External clock	Connected to a crystal resonator. An external clock signal may also be input to the EXTAL pin.
	XTAL	O	Crystal	Connected to a crystal resonator.
	CKIO	O	System clock output	Supplies the system clock to external devices.
	AUDIO_CLK	I	External clock for audio	Input pin of external clock for audio. A clock input to the divider is selected from an oscillation clock input on this pin or pins AUDIO_X1 and AUDIO_X2.
	AUDIO_X1	I	Crystal resonator/ external clock for audio	Pins connected to a crystal resonator for audio. An external clock can be input on pin AUDIO_X1. A clock input to the divider is selected from an oscillation clock input on these pins or the AUDIO_CLK pin.
	AUDIO_X2	O		
	AUDIO_XOUT	O	AUDIO_X1 clock output	Output for the on-chip crystal oscillator on AUDIO_X1 or the external clock signal.
	AUDIO_XOUT2	O	AUDIO_X1 divided-by-two clock output	Output for the on-chip crystal oscillator on AUDIO_X1 or the external clock signal after frequency division of the selected signal by two.
	AUDIO_XOUT3	O	AUDIO_X1 divided-by-three clock output	Output for the on-chip crystal oscillator on AUDIO_X1 or the external clock signal after frequency division of the selected signal by three.
Operating mode control	MD_BOOT1, MD_BOOT0	I	Mode set	Sets the operating mode. Do not change the signal levels on these pins while the $\overline{\text{RES}}$ pin is asserted or until the mode is fixed, after the negation.
	MD_CLK	I	Clock mode set	Sets the clock operating mode. Do not change the signal levels on this pin while the $\overline{\text{RES}}$ pin is asserted or until the mode is fixed, after the negation.
	MD_CLKS	I	SSCG clock mode set	Switches the SSCG circuit on or off. Do not change the signal levels on this pin while the $\overline{\text{RES}}$ pin is asserted or until the mode is fixed, after the negation.
	BSCANP	I	Boundary scan set	Boundary scan setting pin. This pin is set to the high level for a boundary scan and to the low level for normal operation.

Classification	Symbol	I/O	Name	Function
System control	$\overline{\text{RES}}$	I	Power-on reset	This LSI enters the power-on reset state when this signal goes low.
	$\overline{\text{WDTOVF}}$	O	Watchdog timer overflow	Outputs an overflow signal from the watchdog timer.
Interrupts	NMI	I	Non-maskable interrupt	Non-maskable interrupt request pin. It is handled as an FIQ exception. Fix it high when not in use.
	IRQ7 to IRQ0	I	Interrupt requests 7 to 0	Maskable interrupt request pins. Level-input or edge-input detection can be selected. When the edge-input detection is selected, the rising edge, falling edge, or both edges can also be selected.
	TINT121 to TINT0	I	Interrupt requests 121 to 0	Maskable interrupt request pins. High-level-input or rising edge-input detection can be selected.
Address bus	A25 to A0	O	Address bus	Outputs addresses.
Data bus	D31 to D0	I/O	Data bus	Bidirectional data bus.
Bus control	$\overline{\text{CS5}}$ to $\overline{\text{CS0}}$	O	Chip select 5 to 0	Chip-select signals for external memory or devices.
	$\overline{\text{RD}}$	O	Read	Indicates that data is read from an external device.
	RD/$\overline{\text{WR}}$	O	Read/write	Read/write signal.
	$\overline{\text{BS}}$	O	Bus start	Bus-cycle start signal.
	$\overline{\text{AH}}$	O	Address hold	Address hold timing signal for the device that uses the address/data-multiplexed bus.
	$\overline{\text{WAIT}}$	I	Wait	Inserts a wait cycle into the bus cycles during access to the external space.
	$\overline{\text{WE0}}$	O	Byte select	Indicates a write access to bits 7 to 0 of data of external memory or device.
	$\overline{\text{WE1}}$	O	Byte select	Indicates a write access to bits 15 to 8 of data of external memory or device.
	$\overline{\text{WE2}}$	O	Byte select	Indicates a write access to bits 23 to 16 of data of external memory or device.
	$\overline{\text{WE3}}$	O	Byte select	Indicates a write access to bits 31 to 24 of data of external memory or device.
	DQMLL	O	Byte select	Selects bits D7 to D0 when SDRAM is connected.
	DQMLU	O	Byte select	Selects bits D15 to D8 when SDRAM is connected.
	DQMUL	O	Byte select	Selects bits D23 to D16 when SDRAM is connected.
	DQMUU	O	Byte select	Selects bits D31 to D24 when SDRAM is connected.
	$\overline{\text{RAS}}$	O	RAS	Connected to the $\overline{\text{RAS}}$ pin when SDRAM is connected.
	$\overline{\text{CAS}}$	O	CAS	Connected to the $\overline{\text{CAS}}$ pin when SDRAM is connected.
	CKE	O	CK enable	Connected to the CKE pin when SDRAM is connected.

Classification	Symbol	I/O	Name	Function
Direct memory access controller	DREQ0	I	DMA-transfer request	Input pin to receive external requests for DMA transfer.
	DACK0	O	DMA-transfer request accept	Output pin for signals indicating acceptance of external requests from external devices.
	TEND0	O	DMA-transfer end output	Output pin for DMA transfer end.
Multi-function timer pulse unit 2	TCLKA, TCLKB, TCLKC, TCLKD	I	Timer clock input	External clock input pins for the timer.
	TIOC0A, TIOC0B, TIOC0C, TIOC0D Note: TIOC0B pin is not present on products in the 176-pin package.	I/O	Input capture/ output compare (channel 0)	The TGRA_0 to TGRD_0 input capture input/output compare output/PWM output pins.
	TIOC1A, TIOC1B	I/O	Input capture/ output compare (channel 1)	The TGRA_1 and TGRB_1 input capture input/output compare output/PWM output pins.
	TIOC2A, TIOC2B	I/O	Input capture/ output compare (channel 2)	The TGRA_2 and TGRB_2 input capture input/output compare output/PWM output pins.
	TIOC3A, TIOC3B, TIOC3C, TIOC3D	I/O	Input capture/ output compare (channel 3)	The TGRA_3 to TGRD_3 input capture input/output compare output/PWM output pins.
	TIOC4A, TIOC4B, TIOC4C, TIOC4D	I/O	Input capture/ output compare (channel 4)	The TGRA_4 to TGRD_4 input capture input/output compare output/PWM output pins.
Realtime clock	RTC_X1	I	Crystal resonator for realtime clock/ external clock	Connected to 32.768-kHz crystal resonator. The RTC_X1 pin can also be used to input an external clock.
	RTC_X2	O		
Serial communication interface with FIFO	TxD4 to TxD0	O	Transmit data	Data output pins.
	RxD4 to RxD0	I	Receive data	Data input pins.
	SCK4 to SCK0	I/O	Serial clock	Clock input/output pins.
	$\overline{\text{RTS2}}$ to $\overline{\text{RTS0}}$	I/O	Transmit request	Modem control pins.
	$\overline{\text{CTS2}}$ to $\overline{\text{CTS0}}$	I/O	Transmit enable	Modem control pins.
Serial communication interface	SCI_SCK1, SCI_SCK0	I/O	Serial clock	Clock input/output pins.
	SCI_TXD1, SCI_TXD0	O	Transmit data	Data output pins.
	SCI_RXD1, SCI_RXD0	I	Receive data	Data input pins.
	$\overline{\text{SCI\_CTS1}}$/$\overline{\text{RTS1}}$, $\overline{\text{SCI\_CTS0}}$/$\overline{\text{RTS0}}$	I/O	Transmit and receive start control	I/O pins for controlling the start of transmission and reception.
Renesas serial peripheral interface	MOSI2 to MOSI0	I/O	Data	Data I/O pins.
	MISO2 to MISO0	I/O	Data	Data I/O pins.
	RSPCK2 to RSPCK0	I/O	Clock	Clock I/O pins.
	SSL20, SSL10, SSL00	I/O	Slave select	Slave select I/O pins.

Classification	Symbol	I/O	Name	Function
SPI multi I/O bus controller	SPBCLK_0	O	Clock	Clock output pins.
	SPBSSL_0	O	Slave select	Slave select output pins.
	SPBMO0_0/SPBIO00_0, SPBMI0_0/SPBIO10_0, SPBIO20_0, SPBIO30_0, SPBMO1_0/SPBIO01_0, SPBMI1_0/SPBIO11_0, SPBIO21_0, SPBIO31_0	I/O	Data	Data I/O pins for channel.
I2C bus interface	RIIC3SCL to RIIC0SCL	I/O	Serial clock pin	Serial clock I/O pins.
	RIIC3SDA to RIIC0SDA	I/O	Serial data pin	Serial data I/O pins.
Serial sound interface	SSITxD3, SSITxD1, SSITxD0	O	Data output	Serial data output pin.
	SSIRxD3, SSIRxD1, SSIRxD0	I	Data input	Serial data input pin.
	SSIDATA2	I/O	Data I/O	Serial data I/O pins.
	SSISCK3 to SSISCK0	I/O	SSI clock I/O	I/O pins for serial clocks.
	SSIWS3 to SSIWS0	I/O	SSI clock LR I/O	I/O pins for word selection.
Media local bus (RZ/A1L only)	MLB_CLK	I	Clock input	MediaLB clock input pin.
	MLB_SIG	I/O	Signal information I/O	MediaLB signal information I/O pin.
	MLB_DAT	I/O	Data I/O	MediaLB data I/O pin.
CAN interface	CAN_CLK	I	Clock source for CAN communication	Clock source for CAN communication.
	CAN1TX, CAN0TX	O	CAN bus transmit data	Output pins for transmit data on the CAN bus.
	CAN1RX, CAN0RX	I	CAN bus receive data	Input pins for receive data on the CAN bus.
IEBus™ controller (RZ/A1L only)	IETxD	O	IEBus™ controller transmit data	Output pin for transmit data on IEBus™ controller.
	IERxD	I	IEBus™ controller receive data	Input pin for receive data on IEBus™ controller.
Renesas SPDIF interface	SPDIF_OUT	O	Output data	Transmit data output pin.
	SPDIF_IN	I	Input data	Receive data input pin.
LIN interface (RZ/A1L only)	RLIN30TX	O	Output data	Transmit data output pins.
	RLIN30RX	I	Input data	Receive data input pins.
Ethernet controller, EthernetAVB (RZ/A1LU only) Note: Regarding the switching of pin functions between Ethernet controller and EthernetAVB, refer to section 41, Ports.	ET_TXCLK	I	Transmit clock	Clock pin for transmission.
	ET_TXEN	O	Transmit enable	Transmit data enable pin
	ET_TXD3 to ET_TXD0	O	Transmit data	MII transmit data pins.
	ET_COL	I	Collision detection	Collision detection pin.
	ET_TXER	O	Transmit error	Transmit error output pin.
	ET_RXCLK	I	Receive clock	Receive clock pin
	ET_RXDV	I	Receive enable	Receive data enable pin
	ET_RXD3 to ET_RXD0	I	Receive data	MII receive data pins.
	ET_RXER	I	Receive error	Receive error input pin.
	ET_CRS	I	Carrier detection	Carrier detection pin.
	ET_MDC	O	Management data clock	Clock pin for information transfer via MDIO.
	ET_MDIO	I/O	Management data I/O	Bidirectional pin for exchange of management data
EthernetAVB (RZ/A1LU only)	AVB_CAPTURE	I	Timer capture	Capturing input pin for AVTP presentation timer
	AVB_GPTP_EXTERN	I	gPTP timer external clock	External clock pin for gPTP timer

Classification	Symbol	I/O	Name	Function
USB 2.0 host/ function module	DP1, DP0	I/O	USB 2.0 host/function module D+ data	D+ data pins for USB 2.0 host/function module bus.
	DM1, DM0	I/O	USB 2.0 host/function module D– data	D– data pins for USB 2.0 host/function module bus.
	VBUS1, VBUS0	I	VBUS input	Connected to Vbus on USB 2.0 host/ function module bus.
	REFRIN	I	Reference input	Connected to USBAPVss via 5.6-kΩ ± 1% resistance. (QFP package) Connected to Vss via 5.6-kΩ ± 1% resistance. (BGA package)
	USB_X1	I	Crystal resonator/ external clock for USB 2.0 host/function module	Connected to a crystal resonator for USB 2.0 host/function module. An external clock signal may also be input to the USB_X1 pin.
	USB_X2	O		
	USBAPVcc	I	Power supply for transceiver analog pins	Power supply for pins.
	USBAPVss Note: This pin is not present on products in the BGA package.	I	Ground for transceiver analog pins	Ground for pins.
	USBDPVcc Note: This pin is not present on products in the BGA package.	I	Power supply for transceiver digital pins	Power supply for pins.
	USBDPVss Note: This pin is not present on products in the BGA package.	I	Ground for transceiver digital pins	Ground for pins.
	USBAVcc	I	Power supply for transceiver analog core	Power supply for core.
	USBAVss Note: This pin is not present on products in the BGA package.	I	Ground for transceiver analog core	Ground for core.
	USBDVcc Note: This pin is not present on products in the BGA package.	I	Power supply for transceiver digital core	Power supply for core.
	USBDVss Note: This pin is not present on products in the BGA package.	I	Ground for transceiver digital core	Ground for core.
	USBUVcc Note: This pin is not present on products in the BGA package.	I	480-MHz power supply for USB 2.0 host/function module	Power supply for 480-MHz sections
	USBUVss Note: This pin is not present on products in the BGA package.	I	480-MHz ground for USB 2.0 host/function module	Ground for 480-MHz sections
Video display controller 5	LCD0_DATA23 to LCD0_DATA0	O	Output data	Data output pins for panel.
	LCD0_TCON6 to LCD0_TCON0	O	Panel timing adjustment output	Output pins for panel timing adjustment
	LCD0_CLK	O	Panel clock	Panel clock output pins.
	LCD0_EXTCLK	I	Panel clock source	Panel clock source input pins.
	DV0_DATA23 to DV0_DATA0	I	Input data	Data input pins for graphics data.
	DV0_VSYNC	I	VSYNC input	VSYNC input pins.
	DV0_HSYNC	I	HSYNC input	HSYNC input pins.
	DV0_CLK	I	Input clock	Clock input signal pins for graphics data.

Classification	Symbol	I/O	Name	Function
Capture engine unit	VIO_D7 to VIO_D0	I	Input data	Graphics data input pins.
	VIO_CLK	I	Input clock	Graphics data clock input pin.
	VIO_VD	I	VSYNC input	VSYNC input pin.
	VIO_HD	I	HSYNC input	HSYNC input pin.
	VIO_FLD	I	FIELD input	Input pin for field information
SD host interface	SD_CLK_0, SD_CLK_1	O	SD clock	Output pins for SD clock.
	SD_CMD_0, SD_CMD_1	I/O	SD command	SD command output and response input signals.
	SD_D3_0 to SD_D0_0, SD_D3_1 to SD_D0_1	I/O	SD data	SD data bus signals.
	SD_CD_0, SD_CD_1	I	SD card detection	SD card detection.
	SD_WP_0, SD_WP_1	I	SD write protection	SD write protection signals.
MMC host interface	MMC_CLK	O	MMC clock	Output pin for MMC clock.
	MMC_CMD	I/O	MMC command	MMC command output and response input signal.
	MMC_D7 to MMC_D0	I/O	MMC data	MMC data bus signals.
	MMC_CD	I	MMC card detection	MMC card detection.
A/D converter	AN7 to AN0	I	Analog input pins	Analog input pins.
	$\overline{\text{ADTRG}}$	I	A/D conversion trigger input	External trigger input pin for starting A/D conversion.
	AVcc	I	Analog power supply	Power supply pin for A/D converter.
	AVss	I	Analog ground	Ground pin for A/D converter.
	AVref	I	Analog reference voltage	Reference voltage pin for A/D converter.
General I/O ports	P2_0 to P2_9, P3_0 to P3_15, P4_0 to P4_7, P5_0 to P5_15, P6_0 to P6_15, P7_0 to P7_11, P8_0 to P8_15 (208-pin QFP products only), P9_0 to P9_5 (208-pin QFP products only)	I/O	General port	78 general I/O port pins in 176-pin QFP and 176-pin BGA products. 100 general I/O port pins in 208-pin QFP products.
	P1_0 to P1_7	I/O	General port	8 input port pins with open-drain output.
	JP0_0, JP0_1, P0_0 to P0_3, P1_8 to P1_15	I	General port	14 general input port pins.
Debugging interface	TCK/SWDCLK	I	Test clock	Test-clock input pin. Also used as the input clock pin for serial wire debugging
	TMS/SWDIO	I, I/O	Test mode select	Test-mode select signal input pin. Also used as the I/O data pin for serial wire debugging
	TDI	I	Test data input	Serial input pin for instructions and data.
	TDO	O	Test data output	Serial output pin for instructions and data.
	$\overline{\text{TRST}}$	I	Test reset	Initialization-signal input pin. Note: When the chip is in CoreSight debugging mode, do not negate the $\overline{\text{TRST}}$ signal while the $\overline{\text{RES}}$ signal is at the high-level.
	TRACEDATA3 to TRACEDATA0	O	Data output	Trace data output pins.
	TRACECLK	O	Clock output	Trace clock output pin.
	TRACECTL	O	Enable output	Trace enable output pin.

1.6 List of Pins

2. CPU

This product incorporates the Arm single-core Cortex-A9 MPCore, where the IP version is r3p0.

2.1 Features*1

- Instruction cache size: 32 Kbytes
- Data cache size*2: 32 Kbytes
- TLB entries: 128 entries
- Jazelle architecture extension: Full
- Media processing engine with NEON technology: Included
- FPU: Included
- PTM interface: Included
- Wrappers to support for power off and dormant mode: Not included
- Preload engine: Not included
- Number of interrupts: 0 (On-chip interrupt controller is not used.)
- Accelerator Coherence Port: Not included

Note 1. For details, refer to Cortex-A9 MPCore Technical Reference Manual issued by Arm Ltd.
Note 2. Contents of memory regions which are set as write-through are not cached even if data caching is enabled. For details, refer to Cortex-A9 Technical Reference Manual issued by Arm Ltd.

2.2 Configuration Signals

Table 2.1 shows the Cortex-A9 configuration signals and the settings.

Table 2.1 Cortex-A9 Configuration Signal Settings

Configuration Signal	Setting Values
CFGEND	1’b0
CFGNMIF	1’b1
CLUSTERID	4'h0
FILTEREN*1	1’b1
FILTERSTART[31:20]*1	12’hE00
FILTEREND[31:20]*1	12’hFFF
PERIPHBASE[31:13]*2	19’b111_1000_0000_0000_0000
TEINIT	1’b0
VINITHI	NOR, SRAM boot: 1’b0; on-chip ROM boot: 1’b1

Note 1. Do not change the initial settings of these signals by software.
Note 2. The base address for the private memory area in the Cortex-A9 processor is H'F0000000. For details and overview of the registers located in the addresses relative to this base address, refer to Cortex-A9 MPCore Technical Reference Manual issued by Arm Ltd.

3. Boot Mode

This LSI can be booted from the memory connected to the CS0 space, the serial flash memory, the NAND flash memory with an SD controller, and the NAND flash memory with an MMC controller.

3.1 Features

- Four boot modes
  Boot mode 0: Boots the LSI from the memory (bus width: 16 bits) connected to the CS0 space
  Boot mode 1: Boots the LSI from the serial flash memory connected to the SPI multi I/O bus space
  Boot mode 2: Boots the LSI from the NAND flash memory with the SD controller*1
  Boot mode 3: Boots the LSI from the NAND flash memory with the MMC controller*2

Note 1. It is possible to boot the LSI from the embedded SD (eSD) defined by the SD specification part 1 eSD addendum version 2.10 standard.
Note 2. It is possible to boot the LSI from the eMMC device corresponding to the boot operating mode of the JEDEC standard JESD84 A44 (MMCA 4.4) Standard. (It is not possible to boot the LSI from the MMC card.)

3.2 Boot Mode and Pin Function Setting

This LSI can determine the boot mode using external pins when $\overline{\text{RES}}$ is low. The external pin settings for selecting the boot mode are shown in Table 3.1.

Table 3.1 External Pin (MD_BOOT1 and MD_BOOT0) Settings and Corresponding Boot Modes

MD_BOOT1	MD_BOOT0	Boot Mode
0	0	Boot Mode 0 (CS0-space 16-bit booting) Boots the LSI from the memory (bus width: 16 bits) connected to the CS0 space.
1	0	Boot Mode 1 (serial flash booting) Boots the LSI from the serial flash memory connected to the SPI multi I/O bus space.
0	1	Boot Mode 2 (eSD booting) Boots the LSI from the NAND flash memory with the SD controller. The only way of booting this LSI chip is from channel 0 (P3_0 to P3_5) in this mode.
1	1	Boot Mode 3 (eMMC booting) Boots the LSI from the NAND flash memory with the MMC controller.

3.3 Hardware Used in Each Boot Mode

Table 3.2 gives information about the hardware used in each boot mode.

Table 3.2 Hardware Used in Each Boot Mode

Boot Mode	Peripheral Module	Pins Used	Remarks
Boot Mode 0 (CS0-space 16-bit booting)	Bus state controller	A[20:1] D[15:0] $\overline{CS0}$ $\overline{RD}$ CKIO	—
Boot Mode 1 (Serial flash booting)	SPI multi I/O bus controller	SPBCLK_0 SPBSSL_0 SPBMO0_0 SPBMI0_0	The internal baud rate generator generates SPBCLK_0 by dividing Bϕ by 8.
Boot Mode 2 (eSD booting)	SD host interface	SD_CLK_0 SD_CMD_0 SD_D[3:0]_0	The SD clock frequency (SD_CLK_0) is generated by dividing P1ϕ by 4.
Boot Mode 3 (eMMC booting)	MMC host interface	MMC_CLK MMC_CMD MMC_D[3:0]	The MMC clock frequency (MMC_CLK) is generated by diving P1ϕ by 4.

3.4 Exception Vector Address at a Reset in Each Boot Mode

In this LSI, the exception vector address at a reset differs depending on the boot mode.
In this LSI, the exception vector at a reset starts from H'0000_0000 (low vector) in boot mode 0 and from H'FFFF_0000 (high vector) in boot modes 1 to 3.
In this LSI, an on-chip ROM is allocated in area H'FFFF_0000 to H'FFFF_FFFF. The on-chip ROM has a boot program which executes processing corresponding to the boot mode set by the MD_BOOT1 and MD_BOOT0 external pins.
Table 3.3 lists the exception vector address at a reset for each boot mode.

Table 3.3 Exception Vector Address at a Reset in Each Boot Mode

Boot Mode	Exception Vector Address at a Rest	Memory Allocated at the Exception Vector Address
Boot Mode 0 (CS0-space 16-bit booting)	H'0000 0000 (low vector)	Memory connected to the CS0 space
Boot Mode 1 (Serial flash booting)	H'FFFF 0000 (high vector)	On-chip ROM (boot program)
Boot Mode 2 (eSD booting)	H'FFFF 0000 (high vector)	On-chip ROM (boot program)
Boot Mode 3 (eMMC booting)	H'FFFF 0000 (high vector)	On-chip ROM (boot program)

3.5 Operation

3.5.1 Boot Mode 0

In boot mode 0, this LSI is booted from the memory connected to the CS0 space. In these modes, this LSI operates as follows:
After the power-on reset is canceled, program execution is started from H'0000_0000 in the memory connected to the CS0 space.

3.5.2 Boot Mode 1

In boot mode 1, booting up is from the serial flash memory connected to the SPI multi I/O bus space. In this mode, this LSI operates as follows: After the power-on reset is canceled, the boot program stored in the on-chip ROM (starting from H'FFFF_0000) is executed.
The boot program configures the SPI multi I/O bus controller in external address space read mode. With this configuration, this LSI converts reads from the SPI multi I/O bus space to SPI communications and is ready to read directly from the connected serial flash memory. The boot program configures a read command (opcode: 03H, address: 3 bytes, dummy cycle: none) as the command to the serial flash memory used for SPI communication conversion. Figure 3.1 shows the control signals output to the serial flash memory through SPI communication conversion.

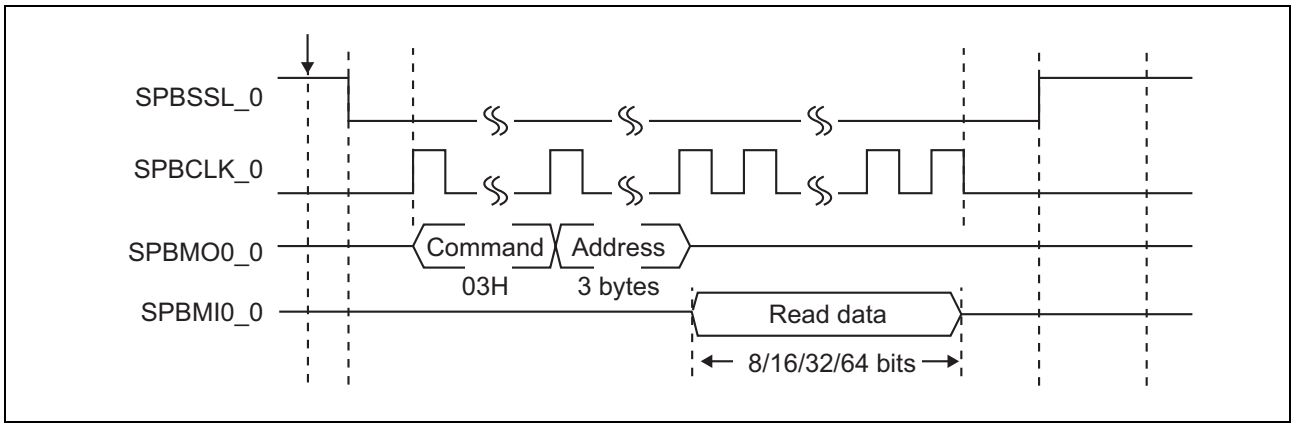

Figure 3.1 Control Signals Output to the Serial Flash Memory Through SPI Communication Conversion

The boot program uses the area at H'2002_0000 to H'2002_3FFF as work memory. It branches to H'1800_0000 (SPI multi I/O bus space) at the end of the processing. At this time, the I bit, F bit, T bit and bits Mode[4:0] in CPSR are set to the initial states with the I bit set to 1'b1 (IRQ masked state), the F bit set to 1'b1 (FIQ masked state), the T bit set to 1'b0 (Arm state) and bits Mode[4:0] set to 5'b10011 (supervisor mode).

3.5.3 Boot Mode 2

In boot mode 2, booting up is from the NAND flash memory with the SD controller, which is connected to channel 0 of the SD host interface. The flow of operation of this LSI in boot mode 4 is as described below.

After a power-on reset, this LSI executes the boot program stored in the on-chip ROM (starting from H'FFFF_0000). The boot program transfers 28 Kbytes of program from the NAND flash memory with the SD controller connected to channel 0 of the SD host interface to the address range from H'2002_4000 to H'2002_AFFF of the large-capacity on-chip RAM.
The program (28 Kbytes) that the boot program transfers to the large-capacity on-chip RAM is called a loader program.

The boot program uses an area from H'2002_0000 to H'2002_3FFF as work memory. Note that the loader program must be stored in the NAND flash memory with the SD controller according to the loader program storage specifications.*1

Note 1. For the storage specifications of the loader program, contact Renesas Electronics Corporation's sales office.

After the boot program finishes processing, it branches to H'2002_4000 (large-capacity on-chip RAM). At this time, the I bit, F bit, T bit and bits Mode[4:0] in CPSR are set to the initial states with the I bit set to 1'b1 (IRQ masked state), the F bit set to 1'b1 (FIQ masked state), the T bit set to 1'b0 (Arm state) and bits Mode[4:0] set to 5'b10011 (supervisor mode).
The size of the loader program that the boot program transfers to the large-capacity on-chip RAM is fixed to 28 Kbytes. If your loader program exceeds this limit, use the loader program to transfer your program (application program) from the NAND flash memory with the SD controller to the large-capacity on-chip or external RAM using channel 0 of the SD host interface. Note that you must design a loader program.

Figure 3.2 is a schematic view of the specification for boot mode 2.

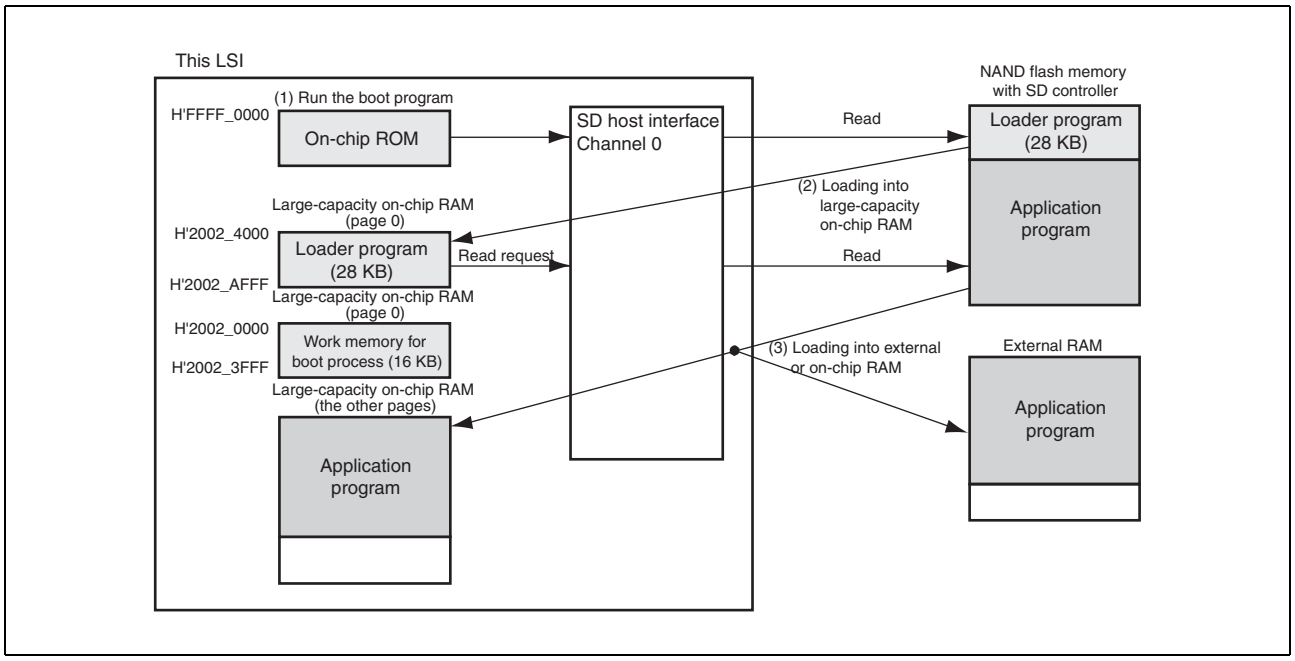

Figure 3.2 Schematic View of Specification for Boot Mode 2

3.5.4 Boot Mode 3

In boot mode 3, booting up is from the NAND flash memory with the MMC controller, which is connected to the MMC host interface. The flow of operation of this LSI in boot mode 5 is as described below.

After a power-on reset, this LSI executes the boot program stored in the on-chip ROM (starting from H'FFFF_0000). The boot program transfers 28 Kbytes of program from the NAND flash memory with the MMC controller connected to the MMC host interface to the address range from H'2002_4000 to H'2002_AFFF of the large-capacity on-chip RAM. The program (28 Kbytes) that the boot program transfers to the large-capacity on-chip RAM is called a loader program.

The boot program uses an area from H'2002_0000 to H'2002_3FFF as work memory. Note that the loader program must be stored in the NAND flash memory with the MMC controller according to the loader program storage specifications.*1

Note 1. For the storage specifications of the loader program, contact Renesas Electronics Corporation's sales office.

After the boot program finishes processing, it branches to H'2002_4000 (large-capacity on-chip RAM). At this time, the I bit, F bit, T bit and bits Mode[4:0] in CPSR are set to the initial states with the I bit set to 1'b1 (IRQ masked state), the F bit set to 1'b1 (FIQ masked state), the T bit set to 1'b0 (Arm state) and bits Mode[4:0] set to 5'b10011 (supervisor mode).
The size of the loader program that the boot program transfers to the large-capacity on-chip RAM is fixed to 28 Kbytes. If your loader program exceeds this limit, use the loader program to transfer your program (application program) from the NAND flash memory with the MMC controller to the large-capacity on-chip or external RAM using the MMC host interface. Note that you must design a loader program.

Figure 3.3 is a schematic view of the specification for boot mode 3.

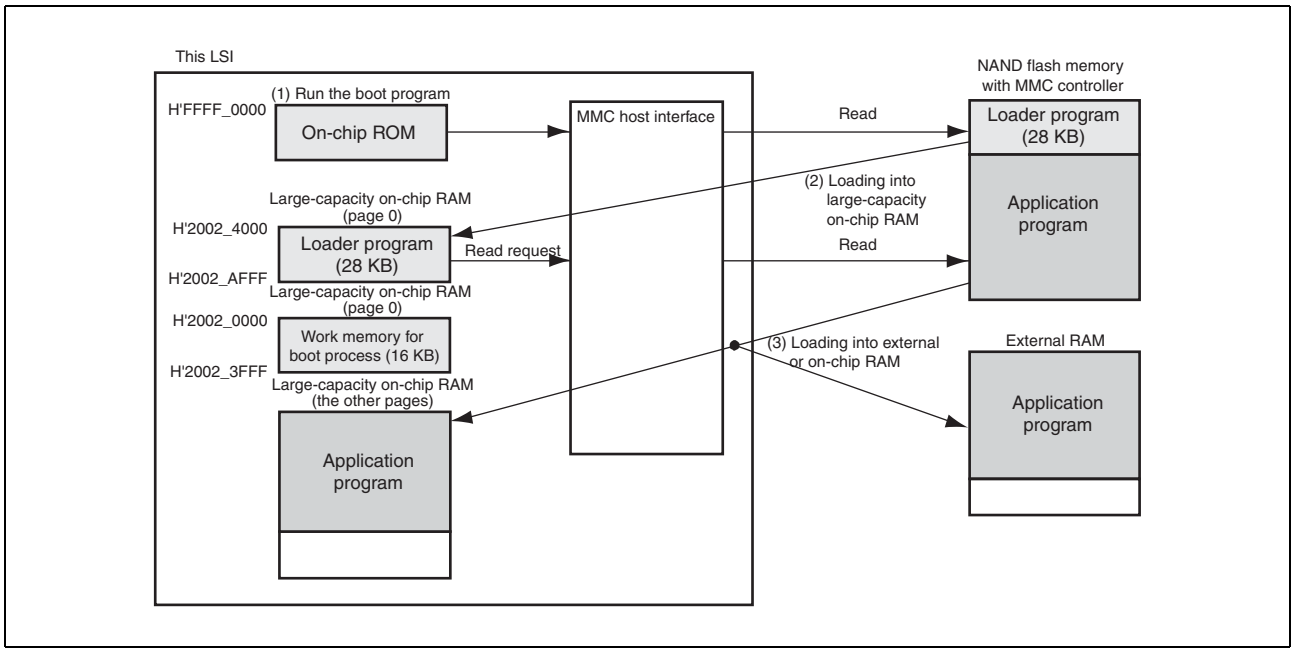

Figure 3.3 Schematic View of Specification for Boot Mode 3

3.6 Notes

3.6.1 Boot Related Pins

The initial states and output states in deep standby mode of the pins related to CS0 space memory read, SPI multi I/O bus space memory read, channel 0 of the SD host interface, and the MMC host interface are different in each boot mode. For details, refer to section 8, Bus State Controller, section 41, Ports, and section 42, Power-Down Modes.

3.6.2 Operation when an Exception Occurs with the Exception Vector Set to the High Vector Address

In this LSI, the program counter loops to its own address (exception vector address) in the on-chip ROM if an exception (except for a reset) occurs when the exception vector is set to the high vector address. In boot mode 1, 2, or 3, set the V bit in SCTLR to 0 to set the exception vector to the low vector address before an exception (except for a reset) occurs. For the details about the CP15 system control register (SCTLR), refer to the Arm Architecture Reference Manual.

3.6.3 Notes on Serial Flash Booting (Boot Mode 1) after This LSI is Reset

In booting up from serial flash memory (boot mode 1), read commands (opcode: 03H, address: 3 bytes, dummy cycles: none) are set for sending to the serial flash memory. Therefore, if this chip enters the reset state while the serial flash memory cannot accept read commands, correct booting up of the chip may not be possible. For example, if the chip is reset while the serial flash memory is being erased (placing it in the busy state), the serial flash memory will not accept read commands. In such cases, that is, in system configurations where the chip may be reset while the serial flash memory is unable to accept read commands, ensure that the serial flash memory is able to accept read commands after the chip is released from the reset state by using serial flash memory that has its own reset pin or cutting off power to the serial flash memory when a reset occurs.

4. Secondary Cache

This product incorporates Arm's PL310 as a secondary cache. The IP version is r3p2.

4.1 Features

- Total cache size: 128 Kbytes
- Number of cache ways: 8 ways
- Number of master ports : 2
- Number of slave ports: 2
- Lockdown by master: No
- Lockdown by line Defined
- Speculative read: No
- Sideband signal from CA9: No

For details, see CoreLink™ Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd.

4.2 Configuration Signals

The setting values of the configuration signals are shown in Table 4.1.

Table 4.1 Setting Values of Configuration Signals

Configuration Signals	Setting Values
ASSOCIATIVITY*1	1'b0 (8 ways)
CACHEID[5:0]	6'b000000
CFGADDRFILTEN*1	1'b1
CFGADDRFILTEND[11:0]*1	12'h3FF
CFGADDRFILTSTART[11:0]*1	12'h180
CFGBIGEND	1'b0
DATAREADLAT[2:0]*1	3'b000
DATASETUPLAT[2:0]*1	3'b000
DATAWRITELAT[2:0]*1	3'b000
REGFILEBASE[19:0]*2	20'h3FFFF
TAGREADLAT[2:0]*1	3'b000
TAGSETUPLAT[2:0]*1	3'b000
TAGWRITELAT[2:0]*1	3'b000
WAYSIZE[2:0]*1	3'b001 (16 Kbytes)

Note 1. Do not change the initial settings of these signals by software.
Note 2. The base address for the PL310 registers is H'3FFFF000. For the details and overview of the registers, see CoreLink™ Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd. The external ROM/RAM mirror area (0x4000_0000 to 0x5FFF_FFFF) is mirrored before the secondary cache. Accordingly, when a cache maintenance operation is to be executed for the external ROM/RAM mirror area, treat this as the normal external ROM/RAM area in the physical addresses range from 0x0000_0000 to 0x1FFF_FFFF.

5. LSI Internal Bus

5.1 LSI Internal Bus

5.1.1 Configuration

This LSI has two main buses: the north main bus where peripheral modules are connected and the south main bus where on-chip RAM and external ROM and RAM are connected. Figure 5.1 is a schematic diagram of the internal buses.

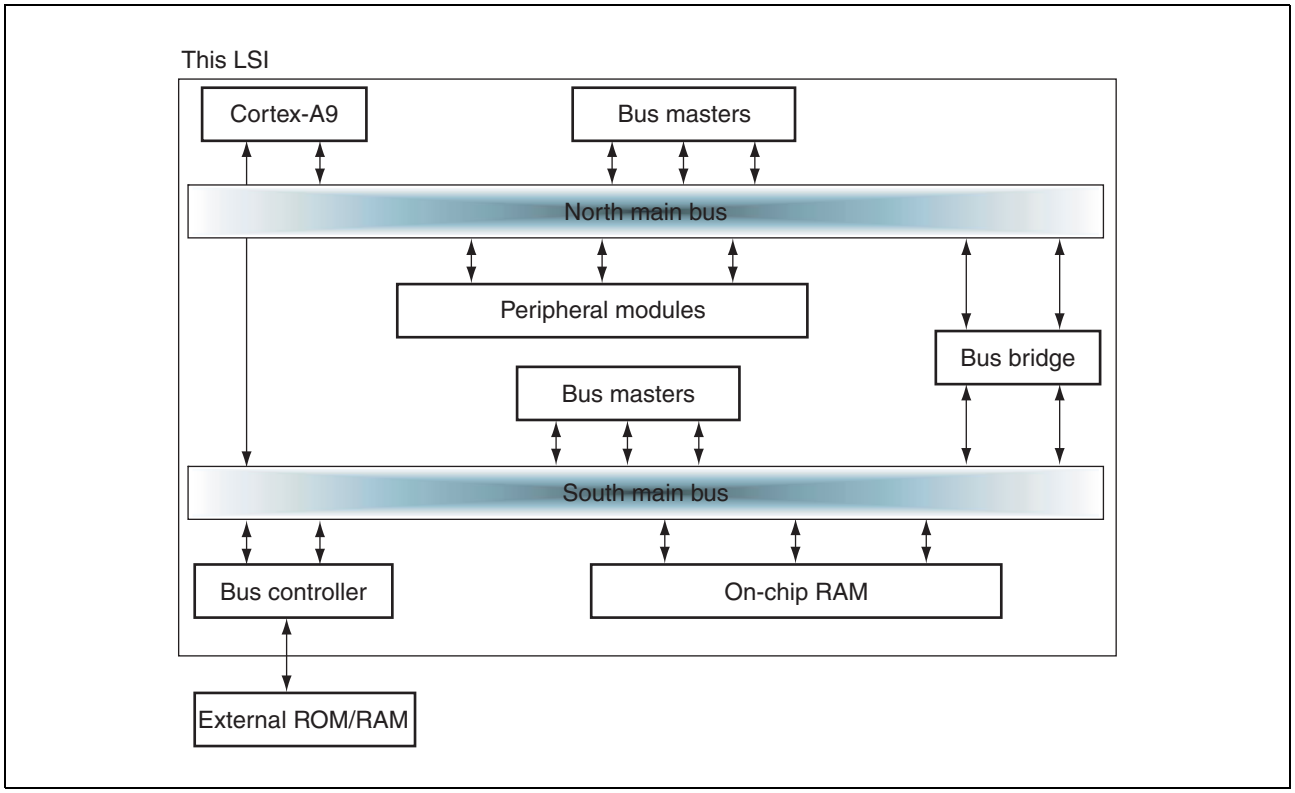

Figure 5.1 Schematic Diagram of LSI Internal Bus

5.1.2 Operation

Cortex-A9 has separate interfaces for the north main bus and south main bus. The addresses assigned to the north main bus are accessed through the north main bus interface, and those assigned to the south main bus are accessed through the south main bus interface.

When a bus master connected to the north main bus, except for Cortex-A9, accesses the on-chip RAM or external ROM or RAM, access is executed through the bus bridge for access from the north main bus to the south main bus. The bus masters connected to the south main bus cannot access an address assigned to the north main bus. The internal bus of this LSI operates in little endian.

5.2 North Main Bus

5.2.1 Configuration

Various peripheral modules are connected to the north main bus. Figure 5.2 shows the configuration of the north main bus.

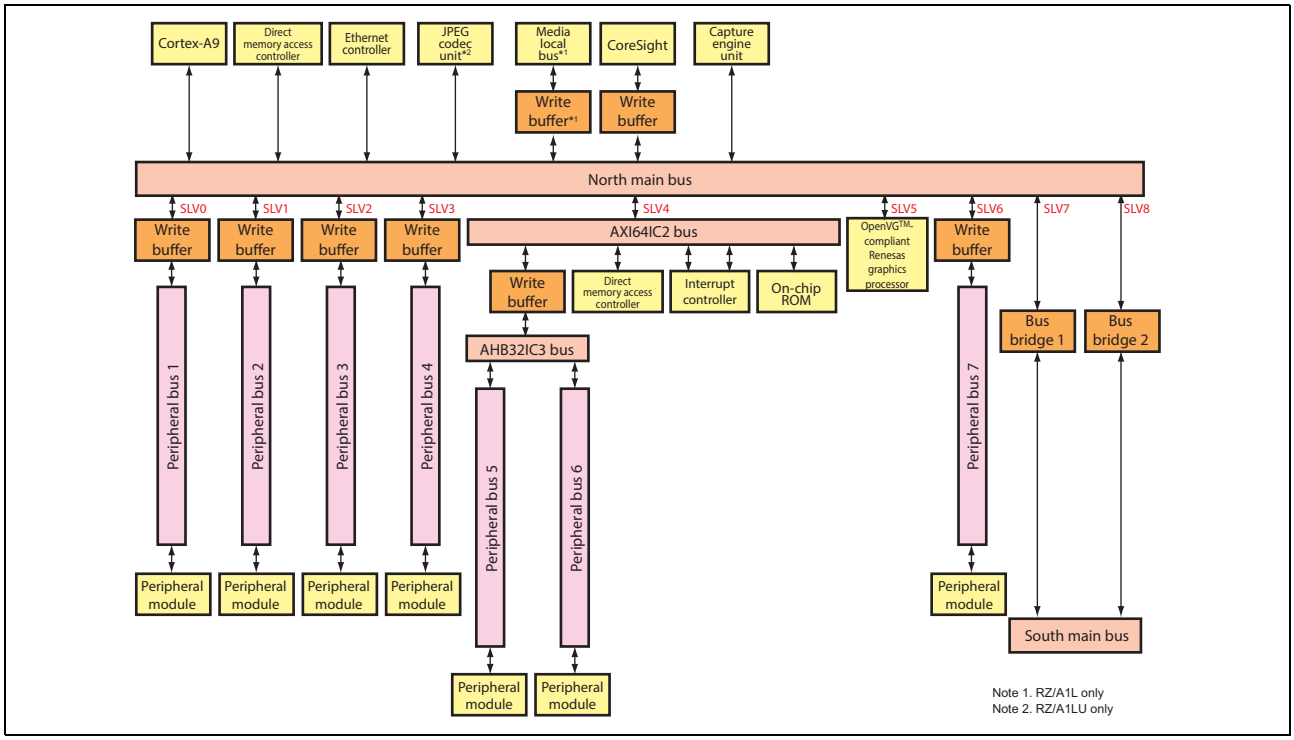

Figure 5.2 North Main Bus Configuration

5.2.2 Features

Table 5.1 shows the features of the north main bus.

Table 5.1 North Main Bus

Item	Description
Bus protocol	AMBA® AXI protocol
Bus system configuration	AXI interconnect with multi-layer configuration for all channels
Bus clock frequency	Bφ
Bus width	64 bits
Arbitration	Round robin

5.2.3 Peripheral Buses

Table 5.2 is a list of the peripheral buses connected to the north main bus.

Table 5.2 List of Peripheral Buses

Item	Description
Peripheral bus 1	
Bus clock frequency	P0φ
Bus width	32 bits
Connected peripheral modules	Multi-function timer pulse unit 2
	Realtime clock
	Video display controller 5
Peripheral bus 2	
Bus clock frequency	P0φ
Bus width	32 bits
Connected peripheral modules	Clock pulse generator
	Interrupt controller
	Direct memory access controller
	OS timer channels 0 and 1
	I^2C bus interface channels 0 to 3
	IEBus controller (RZ/A1L only)
	LIN interface (RZ/A1L only)
	General I/O ports
Peripheral bus 3	
Bus clock frequency	P1φ
Bus width	32 bits
Connected peripheral modules	CAN interface
	Media local bus (RZ/A1L only)
	SD host interface channels 0 and 1
	MMC host interface

0x6018_0000 to 0x601F_FFFF	On-chip large-capacity RAM page 3 mirror area (512 Kbytes)		SLV6
0x6010_0000 to 0x6017_FFFF	On-chip large-capacity RAM page 2 mirror area (512 Kbytes)	SLV8	SLV5
0x6008_0000 to 0x600F_FFFF	On-chip large-capacity RAM page 1 mirror area (512 Kbytes)		SLV4
0x6002_0000 to 0x6007_FFFF	On-chip large-capacity RAM page 0 (including on-chip data retention RAM) mirror area (512 Kbytes)		SLV3
0x6000_0000 to 0x6001_FFFF			SLV2
0x5C00_0000 to 0x5FFF_FFFF	Reserved area	—	—

Table 5.5 Address Map

Address	Area	Slave Area Viewed from North Main Bus Masters	Slave Area Viewed from South Main Bus Masters
0x5800_0000 to 0x5BFF_FFFF	SPI multi I/O bus area mirror area (64 Mbytes)	SLV7	SLV1
0x5400_0000 to 0x57FF_FFFF	CS5 space mirror area (64 Mbytes)		SLV0
0x5000_0000 to 0x53FF_FFFF	CS4 space mirror area (64 Mbytes)		
0x4C00_0000 to 0x4FFF_FFFF	CS3 space mirror area (64 Mbytes)		
0x4800_0000 to 0x4BFF_FFFF	CS2 space mirror area (64 Mbytes)		
0x4400_0000 to 0x47FF_FFFF	CS1 space mirror area (64 Mbytes)		
0x4080_0000 to 0x43FF_FFFF	CS0 space mirror area (64 Mbytes)		
0x4000_0000 to 0x407F_FFFF		—*5	
0x3FFF_C000 to 0x3FFF_FFFF	I/O area	SLV8	
0x3FEF_B000 to 0x3FFF_BFFF	Reserved area	—	—
0x3FEF_A000 to 0x3FEF_AFFF	I/O area	SLV8	SLV1
0x2030_0000 to 0x3FEF_9FFF	Reserved area	—	—
0x2020_0000 to 0x202F_FFFF	On-chip large-capacity RAM page 4 (1 Mbyte) (RZ/A1L and RZ/A1LU only)	SLV7	SLV7
0x2018_0000 to 0x201F_FFFF	On-chip large-capacity RAM page 3 (512 Kbytes)		SLV6
0x2010_0000 to 0x2017_FFFF	On-chip large-capacity RAM page 2 (512 Kbytes)	SLV8	SLV5
0x2008_0000 to 0x200F_FFFF	On-chip large-capacity RAM page 1 (512 Kbytes)		SLV4
0x2002_0000 to 0x2007_FFFF	On-chip large-capacity RAM page 0 (including on-chip data retention RAM) (512 Kbytes)		SLV3
0x2000_0000 to 0x2001_FFFF			SLV2
0x1C00_0000 to 0x1FFF_FFFF	Reserved area	—	—
0x1800_0000 to 0x1BFF_FFFF	SPI multi I/O bus area (64 Mbytes)	SLV8	SLV1
0x1400_0000 to 0x17FF_FFFF	CS5 space (64 Mbytes)		SLV0
0x1000_0000 to 0x13FF_FFFF	CS4 space (64 Mbytes)		
0x0C00_0000 to 0x0FFF_FFFF	CS3 space (64 Mbytes)		
0x0800_0000 to 0x0BFF_FFFF	CS2 space (64 Mbytes)		
0x0400_0000 to 0x07FF_FFFF	CS1 space (64 Mbytes)		
0x0000_0000 to 0x03FF_FFFF	CS0 space (64 Mbytes)		

Note 1. Only Cortex-A9, the direct memory access controller, and CoreSight can access this area. If any other north main bus master accesses this area, a decode error will occur.
Note 2. Only Cortex-A9 and CoreSight can access this area. If any other north main bus master accesses this area, a decode error will occur.
Note 3. If any address from 0xE821_4800 to 0xE822_FFFF is accessed, a decode error or slave error will occur.
Note 4. A slave error may occur depending on the CoreSight state.
Note 5. Modules which are connected to the north main bus and capable of operating as bus masters are as follows.
- Direct memory access controller
- Ethernet controller
- Media local bus
- CoreSight
- Capture engine unit

These modules do not have access to addresses 0x4000_0000 to 0x407F_FFFF. If they attempt access, a decode error will occur. (RZ/A1L only)
Modules which are connected to the south main bus and capable of operating as bus masters are as follows.
- Cortex-A9
- Video display controller 5

These modules can access the address range shown above.
Note 6. If the on-chip large-capacity RAM is accessed while access is disabled, a slave error will occur.
Note 7. If the area indicated as "—" is accessed, a decode error or a slave error will occur.
Note 8. I/O areas should be accessed in the size specified for each slave module.

5.5 Address Remapping

5.5.1 Overview

Execution in Cortex-A9 jumps to an exception vector placed in addresses 0x0000_0000 to 0x0000_001C when an exception such as a reset or an interrupt occurs. The interrupt response time depends on the time to access the memory connected to this area, and when low-speed memory is connected, the overhead is large. To avoid this, the exception vectors can be remapped to the on-chip high-speed RAM by using the MMU or vector base address register, or the address remapping function can be used to allocate the addresses where the exception vectors are placed to the on-chip high-speed RAM.

Figure 5.4 show the address maps before and after address remapping.

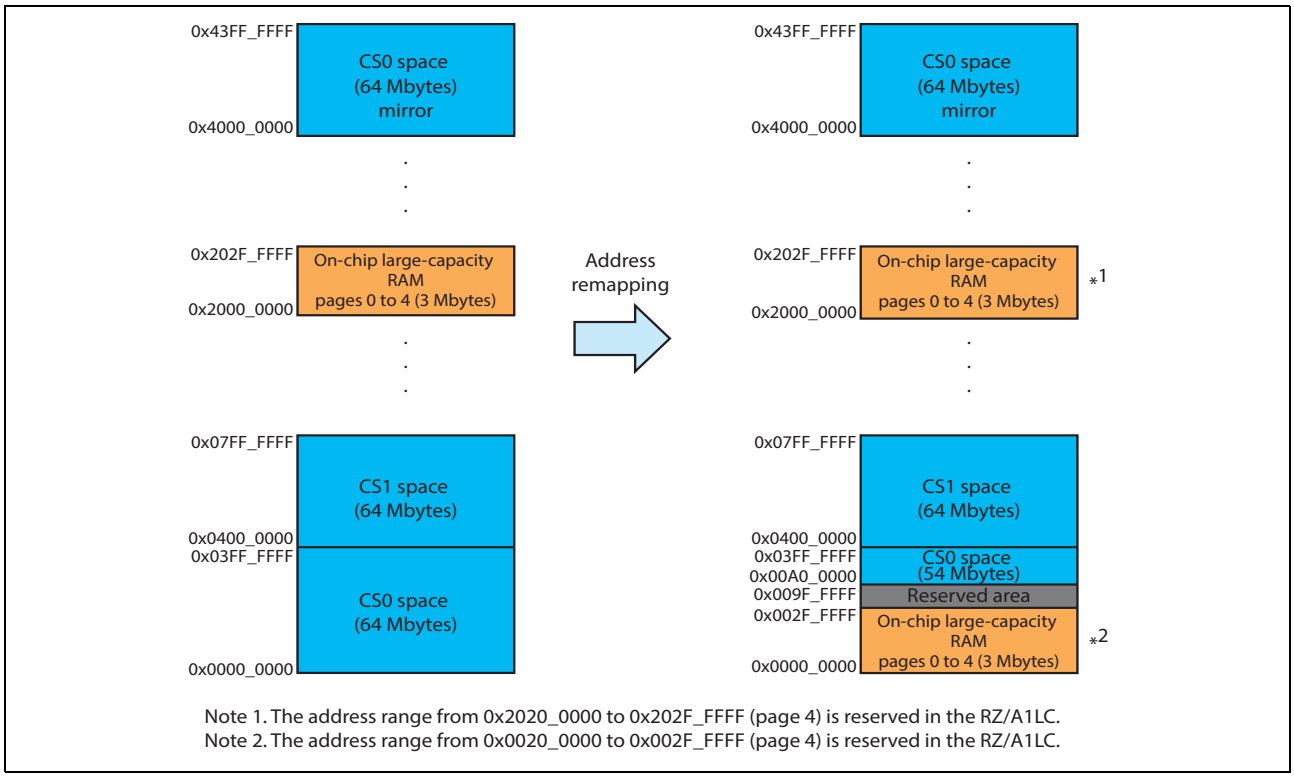

Figure 5.4 Address Remapping

5.5.2 Operation

Addresses are remapped by setting the AXI128 bit in the remap register to 0. After address remapping, pages 0 to 4 (pages 0 to 3 in the RZ/A1LC) of the on-chip large-capacity RAM are allocated to addresses 0x0000_0000 to 0x009F_FFFF. Note that the address range from 0x0030_0000 to 0x009F_FFFF (0x0020_0000 to 0x009F_FFFF in the RZ/A1LC) is reserved. Do not access this area. To access the CS0 space after address remapping, use the mirror area for the CS0 space.

During address remapping, access to addresses 0x0000_0000 to 0x009F_FFFF is prohibited. Accordingly, to modify the remap register, use the following steps.

(1) Stop the bus masters except for Cortex-A9,
or make settings so that addresses 0x0000_0000 to 0x009F_FFFF are never accessed.
(2) Execute a program outside addresses 0x0000_0000 to 0x009F_FFFF.
(3) After modifying the value of the remap register, execute a dummy read of the remap register.

5.6 AXI Interconnect

5.6.1 Configuration

The AXI interconnect in this LSI has a multi-layer configuration in all channels (five channels).
Figure 5.5 shows a conceptual diagram of the AXI interconnect configuration.

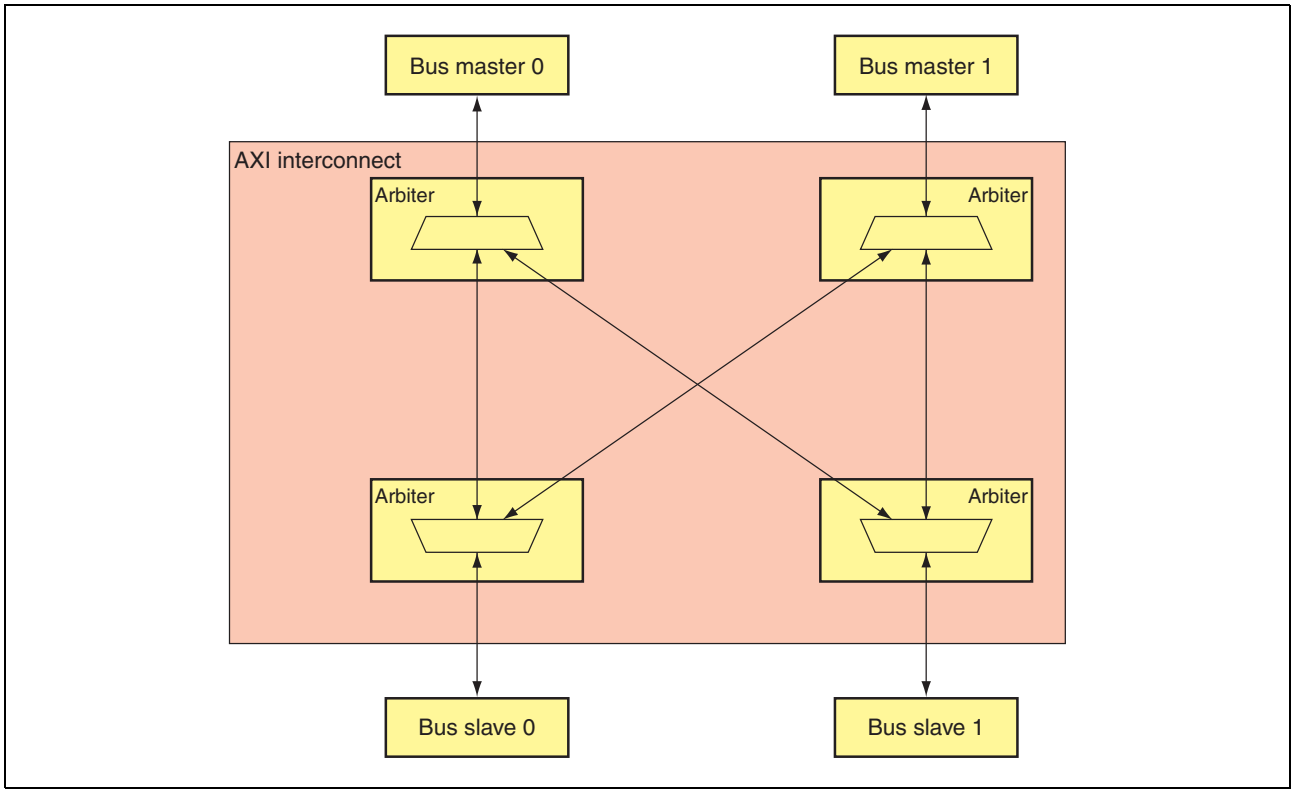

Figure 5.5 Conceptual Diagram of AXI Interconnect Configuration

5.6.2 Operation

In the AXI interconnect, the necessary wiring is prepared for connection between all bus masters and all bus slaves in all channels. When bus masters and slaves access bus slaves and masters, transfer will proceed after bus arbitration by the arbiter. The bus mastership priority changes in a round-robin manner. When multiple bus masters or slaves access different bus slaves or masters, multiple accesses can be executed in parallel. However, when multiple bus masters or slaves access a single bus slave or master at the same time, the bus arbiter executes bus arbitration. When a bus master or slave cannot obtain the bus mastership, it enters a wait state until the bus master or slave that has the bus mastership completes transfer unless the access destination bus master or slave cannot accept multiple transfers. When the destination bus master or slave can accept multiple transfers, bus arbitration is done again with the next transfer timing.

5.7 Bus Bridges

Access from the north main bus to the south main bus is executed through a bus bridge. There are two bus bridges and which bus bridge is used is determined depending on the slave area to be accessed. For assignment of the slave areas to be accessed, see Table 5.5, Address Map.
Each bus bridge can accept up to eight transfers at the same time. Out-of-order transfer is also supported. Therefore, when access to low-speed external ROM and access to on-chip high-speed RAM from different bus masters occur sequentially in this order, the on-chip RAM access can be done without waiting for completion of the previous external ROM access completion.

5.8 AXI Protocol Control Signals

The AXI protocol control signals can be set as desired for each bus master. For details of the AXI protocol control signals, refer to the AMBA AXI Protocol Specification prepared by Arm Ltd.

5.8.1 Bus Masters other than Cortex-A9, CoreSight, and the Direct Memory Access Controller

(1) Cache Control Signals (ARCACHE[3:0] and AWCACHE[3:0])

Use the AXI bus control register (AXIBUSCTL) to make settings of the ARCACHE[3:0] and AWCACHE[3:0] signals for each bus master. Be sure to make settings while the target bus master does not use the AXI bus.

(2) Response Signals (RRESP[1:0] and BRESP[1:0])

Use the AXI bus response error status register (AXIRERRST) to read the RRESP[1:0] and BRESP[1:0] signals received by each bus master. The register value is updated when a response error occurs. The status register value can be cleared to 00 through the AXI bus response error clear register (AXIRERRCLR).
In addition, enabling interrupts through the AXI bus response error interrupt control register (AXIRERRCTL) allows an interrupt to be generated when a response error occurs.
This interrupt should be used only for debugging purposes. Make sure that no response error occurs during system operation.

(3) Protection unit information (ARPROT[2:0], AWPROT[2:0])

Signals ARPROT[2:0] and AWPROT[2:0] are fixed as follows and cannot be modified.
ARPROT[2], AWPROT[2]: 0 (data access)
ARPROT[1], AWPROT[1]: 1*(non-secure access)
ARPROT[0], AWPROT[0]: 0 (normal access)
Note: * For the EthernetAVB, signals ARPROT[1] and AWPROT[1] are fixed to 0 (secure access).

(4) Atomic access (ARLOCK[1:0], AWLOCK[1:0])

Signals ARLOCK[1:0] and AWLOCK[1:0] are fixed as follows and cannot be modified.
ARLOCK[1:0], AWLOCK[1:0]: 00 (normal access)

5.8.2 Cortex-A9

For details on the Cortex-A9, refer to the Arm Architecture Reference Manual.

5.8.3 CoreSight

For details on CoreSight, refer to the technical reference manual issued by Arm Ltd.
The bus master side (AHB access port) of CoreSight is connected to the main bus via the AHB-AXI bus conversion circuit.
The signals are converted as follows for connection to the AXI bus.

(1) Cache control (ARCACHE[3:0], AWCACHE[3:0])

ARCACHE[3], AWCACHE[3]: 0 when HPROT[3] is 0, 1 when HPROT[3] is 1.
ARCACHE[2], AWCACHE[2]: 0 when HPROT[3] is 0, 1 when HPROT[3] is 1.
ARCACHE[1], AWCACHE[1]: Value of HPROT[3] (cacheable)
ARCACHE[0], AWCACHE[0]: Value of HPROT[2] (bufferable)

(2) Response unit (RRESP[1:0], BRESP[1:0])

OKAY is returned when RRESP[1:0] and BRESP[1:0] are 00 or 01.
ERROR is returned when RRESP[1:0] and BRESP[1:0] are 10 or 11.

(3) Protection unit information (ARPROT[2:0], AWPROT[2:0])

ARPROT[2], AWPROT[2]: Inverse of HPROT[0] (data/opcode)
ARPROT[1], AWPROT[1]: Fixed to 1 (non-secure access)
ARPROT[0], AWPROT[0]: Value of HPROT[1] (privileged)

(4) Atomic access (ARLOCK[1:0], AWLOCK[1:0])

ARLOCK[1:0], AWLOCK[1:0]: Fixed to 00 (normal access)

5.8.4 Direct Memory Access Controller

For details on the direct memory access controller, refer to section 9, Direct Memory Access Controller.

5.8.5 Slave Area

The control signals are handled as follows by the modules in the slave area.

(1) Cache control (ARCACHE[3:0], AWCACHE[3:0])

The L2 cache memory and write buffer refer to these signals. Other modules in the slave area do not refer to them.

(2) Response unit (RRESP[1:0], BRESP[1:0])

See Table 5.5, Address Map.

(3) Protection unit information (ARPROT[2:0], AWPROT[2:0])

ARPROT[2], AWPROT[2] (instruction/data): The modules in the slave area do not refer to these signals.
ARPROT[1], AWPROT[1] (non-secure/secure): The interrupt controller and L2 cache memory refer to these signals. Other modules in the slave area do not refer to them.
ARPROT[0], AWPROT[0] (privileged/user): The modules in the slave area do not refer to these signals.

(4) Atomic access (ARLOCK[1:0], AWLOCK[1:0])

This LSI does not support atomic access. Signals ARLOCK[1:0] and AWLOCK[1:0] should be fixed to 00 for normal access by the bus master.*

Note: * This restriction means that instructions for exclusive access (LDREX, STREX, LDREXB, STREXB, LDREXD, STREXD, LDREXH, STREXH) and semaphore instructions (SWP, SWPB) cannot be used by the Cortex-A9 in the internal non-cacheable areas.

5.9 Write Buffers

A write buffer is provided at each connection between the north main bus and a peripheral bus and at each connection between the media local bus and the north main bus, and CoreSight and the north main bus. When the AWCACHE[1:0] cache control signals are set to cache-enabled or buffer-enabled (either of the AWCACHE[1:0] signals is set to 1), the write buffer sends a write completion response to the bus master before accessing the slave area under the write buffer. At this time, even if a slave error response is returned from the slave area to be accessed, it is ignored.

5.10 Register Descriptions

Table 5.6 shows the registers related to the internal bus.

Table 5.6 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Remap register	RMPR	R/W	H'0000_0003	H'FCFE_1A00	32
AXI bus control register 0	AXIBUSCTL0	R/W	H'0000_0000	H'FCFE_1A04	32
AXI bus control register 2	AXIBUSCTL2	R/W	H'0000_0000	H'FCFE_1A0C	32

5.10.1 Remap Register (RMPR)

This register controls the address remapping function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AXI128	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	AXI128	1	R/W	AXI128 Address Remapping This bit enables or disables allocation of addresses H'0000_0000 to H'009F_FFFF to on-chip RAM pages 0 to 4 (pages 0 to 3 in the RZ/A1LC). 0: Address remapping is enabled. 1: Address remapping is disabled.
0	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.

5.10.2 AXI Bus Control Register 0 (AXIBUSCTL0)

This register controls the cache operation for the JPEG codec unit (RZ/A1LU only) and Ethernet controller.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	JCUARCACHE[3:0]*				—	—	—	—	JCUAWCACHE[3:0]*			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	ETHARCACHE[3:0]				—	—	—	—	ETHAWCACHE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 24	JCUARCACHE[3:0]*	0000	R/W	ARCACHE[3:0] Signals for JPEG Codec Unit These bits specify the system cache operation when the JPEG codec unit performs read access. The values of these bits are used as the ARCACHE[3:0] signals for the JPEG codec unit. Modify the values of these bits only while the JPEG codec unit does not use the internal bus.
23 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	JCUAWCACHE[3:0]*	0000	R/W	AWCACHE[3:0] Signals for JPEG Codec Unit These bits specify the system cache operation when the JPEG codec unit performs write access. The values of these bits are used as the AWCACHE[3:0] signals for the JPEG codec unit. Modify the values of these bits only while the JPEG codec unit does not use the internal bus.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	ETHARCACHE [3:0]	0000	R/W	ARCACHE[3:0] Signals for Ethernet Controller These bits specify the system cache operation when the Ethernet controller performs read access. The values of these bits are used as the ARCACHE[3:0] signals for the Ethernet controller. Modify the values of these bits only while the Ethernet controller does not use the internal bus.
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	ETHAWCACHE [3:0]	0000	R/W	AWCACHE[3:0] Signals for Ethernet Controller These bits specify the system cache operation when the Ethernet controller performs write access. The values of these bits are used as the AWCACHE[3:0] signals for the Ethernet controller. Modify the values of these bits only while the Ethernet controller does not use the internal bus.

Note: * These bits are only present in the RZ/A1LU. For the RZ/A1L and RZ/A1LC, the write value should always be 0.

5.10.3 AXI Bus Control Register 2 (AXIBUSCTL2)

This register controls the cache operation for the capture engine unit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CEUAWCACHE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CEUAWCACHE [3:0]	0000	R/W	AWCACHE[3:0] Signals for Capture Engine Unit These bits specify the system cache operation when capture engine unit performs write access. The values of these bits are used as the AWCACHE[3:0] signals for capture engine unit. Modify the values of these bits only while capture engine unit does not use the internal bus.

5.10.4 AXI Bus Control Register 5 (AXIBUSCTL5)

This register is only provided in the RZ/A1L.

This register controls the cache operation for the media local bus.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MLBAXCACHE [1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	MLBAXCACHE [1:0]	00	R/W	AWCACHE[3:0] and ARCACHE[3:0] Signals for Media Local Bus These bits specify the system cache operation when the media local bus performs read or write access. The values of these bits are used as the AWCACHE[3:0] and ARCACHE[3:0] signals for the media local bus. The MLBAXCACHE[0] value is used as ARCACHE[0] and AWCACHE[0] without change. When MLBAXCACHE[1] = 0, the ARCACHE[3:1] and AWCACHE[3:1] signals are all set to 0. When MLBAXCACHE[1] = 1, the ARCACHE[3:1] and AWCACHE[3:1] signals are all set to 1. Modify the values of these bits only while the media local bus does not use the internal bus.

5.10.5 AXI Bus Control Register 6 (AXIBUSCTL6)

This register controls the cache operation for video display controller 5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	VDC501ARCACHE[3:0]				—	—	—	—	VDC501AWCACHE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	VDC502ARCACHE[3:0]				—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 24	VDC501ARCACHE[3:0]	0000	R/W	ARCACHE[3:0] Signals for Video Display Controller 5 IV3-BUS These bits specify the system cache operation when the IV3-BUS of video display controller 5 performs read access. The values of these bits are used as the ARCACHE[3:0] signals for the IV3-BUS of video display controller 5. Modify the values of these bits only while video display controller 5 does not use the internal bus.
23 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	VDC501AWCACHE[3:0]	0000	R/W	AWCACHE[3:0] Signals for Video Display Controller 5 IV1-BUS These bits specify the system cache operation when the IV1-BUS of video display controller 5 performs write access. The values of these bits are used as the AWCACHE[3:0] signals for the IV1-BUS of video display controller 5. Modify the values of these bits only while video display controller 5 does not use the internal bus.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	VDC502ARCACHE[3:0]	0000	R/W	ARCACHE[3:0] Signals for Video Display Controller 5 IV5-BUS These bits specify the system cache operation when the IV5-BUS of video display controller 5 performs read access. The values of these bits are used as the ARCACHE[3:0] signals for the IV5-BUS of video display controller 5. Modify the values of these bits only while video display controller 5 does not use the internal bus.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

5.10.6 AXI Bus Control Register 7 (AXIBUSCTL7)

This register controls the cache operation for video display controller 5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	VDC504ARCACHE[3:0]				—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	VDC504ARCACHE[3:0]	0000	R/W	ARCACHE[3:0] Signals for Video Display Controller 5 IV6-BUS These bits specify the system cache operation when the IV6-BUS of video display controller 5 performs read access. The values of these bits are used as the ARCACHE[3:0] signals for the IV6-BUS of video display controller 5. Modify the values of these bits only while video display controller 5 does not use the internal bus.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

5.10.7 AXI Bus Response Error Interrupt Control Register 0 (AXIRERRCTL0)

This register controls AXI bus response error interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	JCUR ERREN*	—	—	—	ETHR ERREN	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CEUR ERREN	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	JCURERR EN*	0	R/W	Response Error Interrupt Enable for JPEG Codec Unit Enables or disables interrupt requests when access from the JPEG codec unit generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	ETHRERR EN	0	R/W	Response Error Interrupt Enable for Ethernet Controller Enables or disables interrupt requests when access from the Ethernet controller generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
23 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CEURERR EN	0	R/W	Response Error Interrupt Enable for Capture Engine Unit Enables or disables interrupt requests when access from capture engine unit generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * This bit is only present in the RZ/A1LU. For the RZ/A1L and RZ/A1LC, the write value should always be 0.

5.10.8 AXI Bus Response Error Interrupt Control Register 2 (AXIRERRCTL2)

This register controls AXI bus response error interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	VDC501 RERREN	—	—	—	VDC502 RERREN	—	—	—	—	—	—	—	VDC504 RERREN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	VDC501 RERREN	0	R/W	Response Error Interrupt Enable for Video Display Controller 5 IV1/3-BUS Enables or disables interrupt requests when access from the IV1-BUS or IV3-BUS of video display controller 5 generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	VDC502 RERREN	0	R/W	Response Error Interrupt Enable for Video Display Controller 5 IV5-BUS Enables or disables interrupt requests when access from the IV5-BUS of video display controller 5 generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	VDC504 RERREN	0	R/W	Response Error Interrupt Enable for Video Display Controller 5 IV6-BUS Enables or disables interrupt requests when access from the IV6-BUS of video display controller 5 generates a response error. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

5.10.9 AXI Bus Response Error Status Register 0 (AXIRERRST0)

This register indicates occurrence of AXI bus response errors.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	JCURRESP [1:0]*		JCUBRESP [1:0]*		ETHRRESP [1:0]		ETHBRESP [1:0]		—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CEUBRESP [1:0]		—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	JCURRESP [1:0]*	00	R	RRESP[1:0] Signals for JPEG Codec Unit These bits indicate the RRESP[1:0] signals received by the JPEG codec unit. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
29, 28	JCUBRESP [1:0]*	00	R	BRESP[1:0] Signals for JPEG Codec Unit These bits indicate the BRESP[1:0] signals received by the JPEG codec unit. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
27, 26	ETHRRESP[1:0]	00	R	RRESP[1:0] Signals for Ethernet Controller These bits indicate the RRESP[1:0] signals received by the Ethernet controller. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
25, 24	ETHBRESP [1:0]	00	R	BRESP[1:0] Signals for Ethernet Controller These bits indicate the BRESP[1:0] signals received by the Ethernet controller. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
23 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	CEUBRESP[1:0]	00	R	BRESP[1:0] Signals for Capture Engine Unit These bits indicate the BRESP[1:0] signals received by capture engine unit. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * These bits are only present in the RZ/A1LU. For the RZ/A1L and RZ/A1LC, these bits are always read as 0. The write value should always be 0.

5.10.10 AXI Bus Response Error Status Register 2 (AXIRERRST2)

This register indicates occurrence of AXI bus response errors.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VDC501RRESP [1:0]		VDC501BRESP [1:0]		VDC502RRESP [1:0]		—	—	—	—	—	—	VDC504RRESP [1:0]		—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	VDC501RRESP [1:0]	00	R	RRESP[1:0] Signals for Video Display Controller 5 IV3-BUS These bits indicate the RRESP[1:0] signals received by the IV3-BUS of video display controller 5. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
29, 28	VDC501BRESP [1:0]	00	R	BRESP[1:0] Signals for Video Display Controller 5 IV1-BUS These bits indicate the BRESP[1:0] signals received by the IV1-BUS of video display controller 5. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
27, 26	VDC502RRESP [1:0]	00	R	RRESP[1:0] Signals for Video Display Controller 5 IV5-BUS These bits indicate the RRESP[1:0] signals received by the IV5-BUS of video display controller 5. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
25 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19, 18	VDC504RRESP [1:0]	00	R	RRESP[1:0] Signals for Video Display Controller 5 IV6-BUS These bits indicate the RRESP[1:0] signals received by the IV6-BUS of video display controller 5. The values of these bits are updated when a response error occurs. 00: OKAY 10: SLVERR 11: DECERR
17 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

5.10.11 AXI Bus Response Error Clear Register 0 (AXIRERRCLR0)

This register clears the AXI bus response error status.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	JCU RRESP CLR*	—	JCU BRESP CLR*	—	ETH RRESP CLR	—	ETH BRESP CLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R	R/W	R	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CEU BRESP CLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	JCURRESP CLR*	0	R/W	JCURRESP[1:0] Clear Writing 1 to this bit clears the JCURRESP[1:0] bits to 00. This bit is always read as 0.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28	JCUBRESP CLR*	0	R/W	JCUBRESP[1:0] Clear Writing 1 to this bit clears the JCUBRESP[1:0] bits to 00. This bit is always read as 0.
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26	ETHRRESP CLR	0	R/W	ETHRRESP[1:0] Clear Writing 1 to this bit clears the ETHRRESP[1:0] bits to 00. This bit is always read as 0.
25	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
24	ETHBRESP CLR	0	R/W	ETHBRESP[1:0] Clear Writing 1 to this bit clears the ETHBRESP[1:0] bits to 00. This bit is always read as 0.
23 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CEUBRESP CLR	0	R/W	CEUBRESP[1:0] Clear Writing 1 to this bit clears the CEUBRESP[1:0] bits to 00. This bit is always read as 0.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * This bit is only present in the RZ/A1LU. For the RZ/A1L and RZ/A1LC, the write value should always be 0.

5.10.12 AXI Bus Response Error Clear Register 2 (AXIRERRCLR2)

This register clears the AXI bus response error status.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	VDC501 RRESP CLR	—	VDC501 BRESP CLR	—	VDC502 RRESP CLR	—	—	—	—	—	—	—	VDC504 RRESP CLR	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R	R/W	R	R	R	R	R	R	R	R/W	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	VDC501 RRESP CLR	0	R/W	VDC501RRESP[1:0] Clear Writing 1 to this bit clears the VDC501RRESP[1:0] bits to 00. This bit is always read as 0.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28	VDC501 BRESP CLR	0	R/W	VDC501BRESP[1:0] Clear Writing 1 to this bit clears the VDC501BRESP[1:0] bits to 00. This bit is always read as 0.
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26	VDC502 RRESP CLR	0	R/W	VDC502RRESP[1:0] Clear Writing 1 to this bit clears the VDC502RRESP[1:0] bits to 00. This bit is always read as 0.
25 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18	VDC504 RRESP CLR	0	R/W	VDC504RRESP[1:0] Clear Writing 1 to this bit clears the VDC504RRESP[1:0] bits to 00. This bit is always read as 0.
17 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

5.11 Interrupt Request

When a decode error or a slave error occurs, an AXI bus response error interrupt request (PRRI) is issued.
An interrupt request is issued when a response is returned from the bus for which interrupt requests are enabled through the AXI bus response error interrupt control register (AXIRERRCTL). To check the response error type, read the AXI bus response error status register (AXIRERRST). To clear the interrupt request, clear the AXI bus response error status register through the AXI bus response error clear register (AXIRERRCLR).
This interrupt should be used only for debugging purposes. Make sure that no response error occurs during system operation.

6. Clock Pulse Generator

This LSI has a clock pulse generator that generates a CPU clock (Iφ), internal bus clock (Bφ), peripheral clock 1 (P1φ), and peripheral clock 0 (P0φ). The clock pulse generator consists of a crystal oscillator, PLL circuits, and divider circuits.

6.1 Features

- Clock types
  A CPU clock (Iφ); an internal bus clock (Bφ); peripheral clock 1 (P1φ = CKIO) for the external bus interface; peripheral clock 0 (P0φ) for the on-chip peripheral modules
- Frequency change function
  The CPU clock frequency can be changed using the PLL (phase locked loop) circuits and divider circuits within this module. The frequency is changed by software using frequency control register (FRQCR) setting.
- Power-down mode control
  The clock can be stopped in sleep mode, software standby mode, and deep standby mode, and specific modules can be stopped using the module standby function. For details on clock control in the power-down modes, see section 42, Power-Down Modes.
- SSCG function
  The CPU's internal PLL (phase locked loop) circuit includes an SSCG (spread spectrum clock generator).
  The SSCG can be used to decrease the peak value of EMI (electromagnetic interference) noise by frequency modulation, that is, by slightly modulating the output frequency.
  The specification of the SSCG for this LSI is as follows.
  —Specification of SSCG
  (1) Modulation waveform (modulation profile): Triangle wave
  (2) Type of spreading: Down-spreading
  (3) Modulation rate: -3.3% (clock mode 0), -3.1% (clock mode 1)
  (4) Modulation frequency: 20.00 to 26.67 kHz (frequency on the EXTAL pin ÷ 500)
  24.00 kHz (frequency on the USB_X1 pin x (1/4) ÷ 500)

Figure 6.1 shows a block diagram of the clock pulse generator.

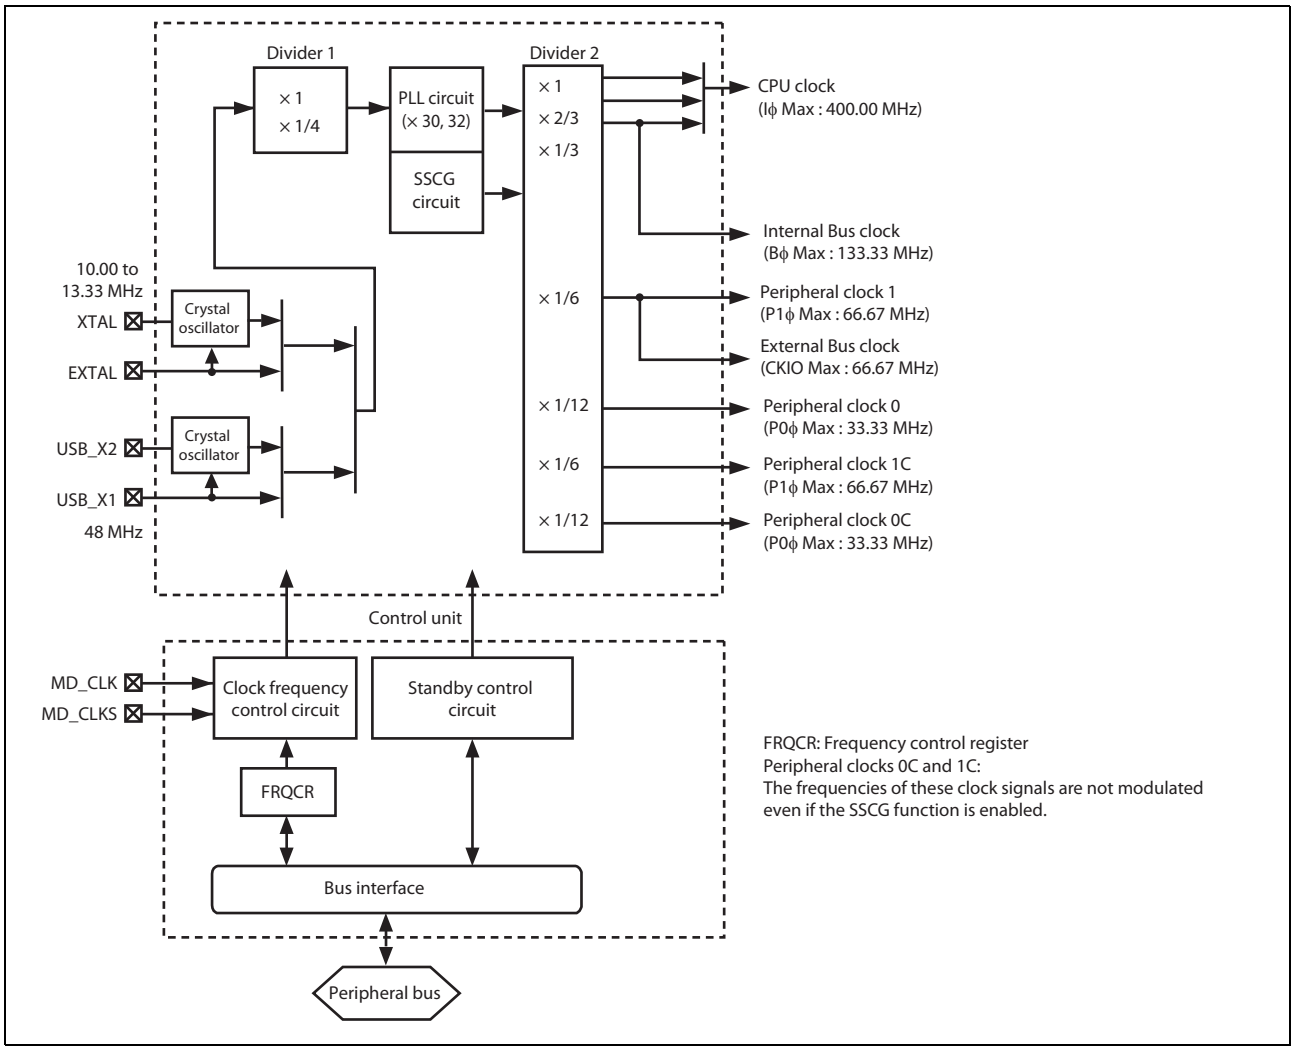

Figure 6.1 Block Diagram

The blocks of this module function as follows:

(1) Crystal Oscillator

A crystal oscillator is connected to the XTAL and EXTAL pins or to the USB_X2 and USB_X1 pins. Either the EXTAL or USB_X1 pin is selected by the clock mode settings.

(2) PLL Circuit

The PLL circuit is capable of multiplying the frequency of the input clock signal from the EXTAL pin by 30. If the input clock signal from the USB_X1 pin is selected, the frequency is multiplied by 32.

(3) Divider 1 and Divider 2

The ratio for frequency division by divider 1 is fixed to 1/1 for the input from the EXTAL pin and 1/4 for the input from the USB_X1 pin.
Divider 2 generates a clock signal whose operating frequency can be used for the CPU clock, internal bus clock, peripheral clock 1, and peripheral clock 0. The division ratio of the CPU clock is set by the frequency control register (FRQCR). The division ratios for peripheral clocks 1 and 0 are fixed to 1/6 and 1/12, respectively.

(4) Clock Frequency Control Circuit

The clock frequency control circuit controls the clock frequency using the frequency control register (FRQCR).

(5) Standby Control Circuit

The standby control circuit controls the states of the on-chip oscillation circuit and other modules during clock switching, or, software standby or deep standby mode.
In addition, the standby control register is provided to control the power-down mode of other modules. For details on the standby control register, see section 42, Power-Down Modes.

(6) Frequency Control Register (FRQCR)

The frequency control register (FRQCR) has control bits assigned for the following functions: clock output/non-output from the CKIO pin during software standby mode or deep standby mode and the frequency division ratio of the CPU clock (Iφ).

(7) SSCG Circuit

Operation of the SSCG circuit is switched on or off (enabled or disabled) by the MD_CLKS pin. When the SSCG function is disabled, all of the internal clock frequencies are fixed, i.e. not modulated. When the SSCG function is enabled, the frequencies of clock signals supplied to peripheral modules other than those listed below are modulated.

Peripheral modules to which non-modulated clock signals are supplied:
IEBus™ controller (RZ/A1L only), multi-function timer pulse unit 2, serial communications interface with FIFO, CAN interface, OS timer, LIN interface (RZ/A1L only), and serial communication interface.

6.2 Input/Output Pins

Table 6.1 lists the clock pulse generator pins and their functions.

Table 6.1 Pin Configuration and Functions of the Clock Pulse Generator

Pin Name	Symbol	I/O	Function
Mode control pin	MD_CLK	Input	Switches between the EXTAL input and the USB_X1 input.
	MD_CLKS	Input	Enables or disables the SSCG circuit.
Crystal input/output pins (clock input pins)	XTAL	Output	Connected to the crystal resonator. (Leave this pin open when the crystal resonator is not in use.)
	EXTAL	Input	Connected to the crystal resonator or used to input external clock.
	USB_X2	Output	Connected to the crystal resonator. (Leave this pin open when the crystal resonator is not in use.)
	USB_X1	Input	Connected to the crystal resonator or used to input external clock.
Clock output pin	CKIO	Output	Clock output pin.

6.3 Clock Mode

Table 6.2 indicates the input/output clock frequency. Table 6.3 shows the usable frequency ranges.

Table 6.2 Input/Output Clock Frequency

Mode	MD_CLK Pin Setting	Clock I/O Source	Output	Divider 1	PLL Circuit	CKIO Frequency
0	0	EXTAL/crystal resonator	CKIO	1	ON (x30)	(EXTAL/crystal resonator) x5
1	1	USB_X1/crystal resonator	CKIO	1/4	ON (x32)	(USB_X1/crystal resonator) x5

In clock mode 0, the clock signal is the input from the EXTAL pin or the crystal oscillator. The PLL circuit shapes waveforms and multiples the frequency, and then supplies the clock to the LSI. The oscillating frequency for the crystal resonator and EXTAL pin input clock ranges from 10 to 13.33 MHz. The frequency range of CKIO is from 50 to 66.67 MHz.

In clock mode 1, the clock signal is the input from the USB_X1 pin or the crystal oscillator. The PLL circuit shapes waveforms and multiples the frequency, and then supplies the clock to the LSI. The oscillating frequency for the crystal resonator and USB_X1 pin input clock is 48 MHz. The frequency of CKIO is 64 MHz.
When changing the frequency, be sure to set the standby_mode_en bit of the power control register in the PL310. For details on the register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd.

After the setting of IFC[1:0] in the frequency control register is changed, the hardware automatically stops the bus master and starts changing the frequency following the wait for completion of the issuing-finished request from the bus master. Since processing to change the frequency cannot start if completion of the issuing-finished request is not possible at this time, do not proceed with access to the registers of modules in the module-standby state and so on. Furthermore, as the issuing of unintended requests by the bus master is inhibited, using software to stop all bus masters in preparation for proceeding to change the frequency is also effective.

Table 6.3 Settable Frequency Ranges

Mode	FRQCR Setting *1	PLL Frequency Multiplier: PLL Circuit	Ratio of Internal Clock Frequencies (I : B : P1 : P0)*2	Selectable Frequency Range (MHz): Input Clock*3	Output Clock (CKIO Pin)	CPU Clock (Iφ)	Internal Bus Clock (Bφ)	Peripheral Clock 1 (P1φ)	Peripheral Clock 0 (P0φ)
0	H'x035	ON (× 30)	30 : 10 : 5 : 5/2	10.00 to 13.33	50.00 to 66.67	300.00 to 400.00	100.00 to 133.33	50.00 to 66.67	25.00 to 33.33
	H'x135		20 : 10 : 5 : 5/2			200.00 to 266.67			
	H'x335		10 : 10 : 5 : 5/2			100.00 to 133.33			
1	H'x035	ON (× 32)	8 : 8/3 : 4/3 : 2/3	48.00	64.00	384.00	128.00	64.00	32.00
	H'x135		16/3 : 8/3 : 4/3 : 2/3			256.00			
	H'x335		8/ 3 : 8/3 : 4/3 : 2/3			128.00			

Note 1. x in the FRQCR register setting depends on the set value in bits 12, 13, and 14.
Note 2. The ratio of clock frequencies, where the input clock frequency is assumed to be 1.
Note 3. In clock mode 0, the frequency of the EXTAL pin input clock or the crystal resonator.
In clock mode 1, the frequency of the USB_X1 pin input clock or the crystal resonator.
Caution: Do not use this LSI for frequency settings other than those in Table 6.3.

The clock source of the chip is switched by the setting of the MD_CLK pin while the $\overline{\text{RES}}$ pin is being held low. The following table shows the correspondence between clock source and pin settings.

Table 6.4 Clock Source Selection

MD_CLK Pin Setting	Clock Source
0	EXTAL/crystal resonator
1	USB_X1/crystal resonator

The SSCG function of the chip is switched on or off by the setting of the MD_CLKS pin while the $\overline{\text{RES}}$ pin is being held low. The following table shows the correspondence between SSCG operation and pin settings. Note that the pin setting does not affect the PLL frequency multipliers and division ratios for individual clock signals.

Table 6.5 SSCG Operation Setting

MD_CLKS Pin Setting	SSCG Operation
0	Off
1	On

6.4 Register Descriptions

Table 6.6 shows the register configuration of the clock pulse generator.

Table 6.6 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Frequency control register	FRQCR	R/W	H'0335	H'FCFE0010	16

6.4.1 Frequency Control Register (FRQCR)

FRQCR is a 16-bit readable/writable register used to specify whether a clock is output from the CKIO pin during normal operation mode, change of gain of crystal oscillator for the XTAL pin, software standby mode, deep standby mode, and standby mode cancellation. The register specifies the frequency division ratio for the CPU clock (Iφ). FRQCR can be accessed in 16-bit units.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	CKOEN2	CKOEN[1:0]		-	-	IFC[1:0]		-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	1	1	0	0	1	1	0	1	0	1
R/W:	R	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14	CKOEN2	0	R/W	Clock Output Enable 2 Specifies whether the CKIO pin outputs clock signals or is fixed to the low level when the gain of the crystal oscillator for the XTAL pin is changed. If this bit is set to 1, the CKIO pin is fixed to the low level when the gain of the crystal oscillator for the XTAL pin is changed. Therefore, the malfunction of an external circuit caused by an unstable CKIO clock while changing the gain of the crystal oscillator for the XTAL pin can be prevented. 0: Unstable clock output 1: Low-level output
13, 12	CKOEN[1:0]	00	R/W	Clock Output Enable These bits specify whether the CKIO pin outputs clock signals, or is set to a fixed level or high impedance (Hi-Z) during normal operation mode, deep standby mode, software standby mode, or cancellation of standby mode. If these bits are set to 01, the CKIO pin is fixed at low during deep standby mode, software standby mode, or cancellation of software standby mode. Therefore, the malfunction of an external circuit caused by an unstable CKIO clock during cancellation of software standby mode can be prevented. Table 6.7 lists CKOEN[1:0] settings.
11, 10	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	IFC[1:0]	11	R/W	CPU Clock Frequency Division Ratio These bits specify the frequency division ratio of the CPU clock with respect to the output frequency of PLL circuit. Note: See section 6.5.1. 00: 1/1 time 01: 2/3 time 10: Reserved (setting prohibited) 11: 1/3 time
7, 6	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	—	11	R	Reserved These bits are always read as 1. The write value should always be 1.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.

Table 6.7 CKOEN[1:0] Settings

Setting	Normal Operation	Software Standby Mode	Deep Standby Mode*
00	Output	Output off (Hi-Z)	Output off (Hi-Z)
01	Output	Low-level output	Low-level output
10	Output	Output (unstable clock output)	Low-level or high-level output
11	Output off (Hi-Z)	Output off (Hi-Z)	Output off (Hi-Z)

Note: * Note that the first cycle of the output CKIO clock may be missing after release from deep standby.

6.5 Changing the Frequency

The frequency of the CPU clock (Iφ) can be changed by changing the division rate of divider. The division rate can be changed by software through the frequency control register (FRQCR).

6.5.1 Changing the Division Ratio

The division rate of divider can be changed by the following operation.

1. In the initial state, IFC[1:0] = B'11.
2. Set the desired value in the IFC[1:0] bits. Note that if the wrong value is set, this LSI will malfunction.
3. After the register bits (IFC[1:0]) have been set, the clock is supplied of the new division ratio.

Note: When executing the WFI instruction after changing the frequency, be sure to read the frequency control register (FRQCR) to confirm that the new setting is in place and read the ISBUSY0 bit in the CPU status register (CPUSTS) to confirm that it is set to 0 beforehand.
For the CPUSTS register, see section 42, Power-Down Modes.

6.6 Usage of the Clock Pins

For the connection of a crystal resonator or the input of a clock signal, this LSI circuit has the pins listed in Table 6.8. With regard to these pins, take care on the following points. Furthermore, Xin pin and Xout pin are used in this section to refer to the pins listed in the table.

Table 6.8 Clock Pins

Xin Pins (Used for Connection of a Crystal Resonator and Input of External Clock Signals)	Xout Pins (Used for Connection of a Crystal Resonator)
EXTAL	XTAL
USB_X1	USB_X2
AUDIO_X1	AUDIO_X2
RTC_X1	RTC_X2

6.6.1 In the Case of Inputting an External Clock

An example of the connection of an external clock is shown in Figure 6.2. In cases where the Xout pin is left open state, take the parasitic capacitance as less than 10 pF.

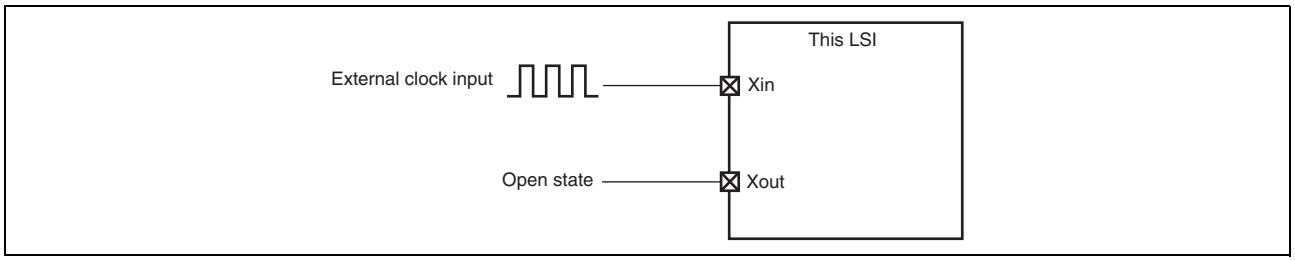

Figure 6.2 Example of the Connection of an External Clock

6.6.2 In the Case of Using a Crystal Resonator

An example of the connection of crystal resonator is shown in Figure 6.3.

Place the crystal resonator and capacitors (CL1 and CL2) as close to pins Xin and Xout as possible. Furthermore, to avoid inductance so that oscillation is correct, use the points where the capacitors are connected to the crystal resonator in common and do not place wiring patterns close to these components.

Since the design of the user board is closely connected with the effective characteristics of the crystal resonator, refer to the example of connection of the crystal resonator that is introduced in this section and perform thorough evaluation on the user side as well. The rated value of the crystal resonator will vary with the floating capacitances and so on of the crystal resonator and mounted circuit, so proceed with decisions on the basis of full discussions with the maker of the crystal resonator. Ensure that voltages applied to the clock pins do not exceed the maximum rated values.

Although the feedback resistor is included in this LSI, an external feedback resistor may be required in some cases. This depends on the characteristics of the crystal resonator.

Set the parameters (of resistors and capacitors) with thorough evaluation on the user side.

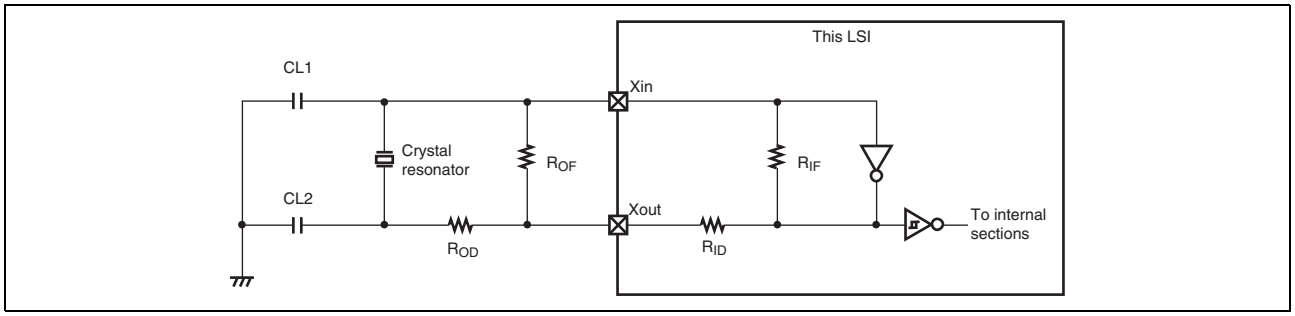

Figure 6.3 Example of the Connection of a Crystal Resonator

6.6.3 In the Case of Not Using the Clock Pin

In cases where the pins are not in use, fix the level on the Xin pin (pull it up or down, or connect it to the power-supply or ground level), and leave the Xout pin open state.

6.7 Oscillation Stabilizing Time

6.7.1 Oscillation Stabilizing Time of the On-chip Crystal Oscillator

In the case of using a crystal resonator, wait for the oscillation stabilizing time of the on-chip oscillation circuit at the following cases, to keep the oscillation stabilizing time of the on-chip crystal oscillator (in the case of inputting an external clock input, it is not necessary).

- Power on
- Releasing the software standby mode or deep standby mode by $\overline{\text{RES}}$ pin
- Changing from halting oscillation to running oscillation by power-on reset or register setting (AUDIO_X1)
- Changing from halting oscillation to running oscillation by register setting (RTC_X1)
- Changing the gain of the on-chip crystal oscillator by $\overline{\text{RES}}$ pin (EXTAL)

6.7.2 Oscillation Stabilizing Time of the PLL circuit

The clock from EXTAL is supplied to the PLL circuit. So, regardless of whether using a crystal resonator or inputting an external clock from EXTAL, wait for at least the oscillation stabilizing time at the following cases, to keep the oscillation stabilizing time of the PLL circuit.

- Power on (in the case of using the crystal resonator)/start inputting external clock (in the case of inputting the external clock)
- Releasing the software standby mode or deep standby mode by $\overline{\text{RES}}$ pin

[Remarks]
The oscillation stabilizing time is kept by the counter running in the LSI at the following cases.

- Releasing the software standby mode or deep standby mode by the other than $\overline{\text{RES}}$ pin
- Changing the gain of the on-chip crystal oscillator by the register setting (EXTAL)

6.8 Notes on Board Design

6.8.1 Note on Using a PLL Oscillation Circuit

In the PLLVcc connection pattern for the PLL, signal lines from the board power supply pins must be as short as possible and pattern width must be as wide as possible to reduce inductive interferences.

Since the analog power supply pins of the PLL are sensitive to the noise, the system may malfunction due to inductive interference at the other power supply pins. To prevent such malfunction, the analog power supply pins and the digital power supply pins Vcc and PVcc should not supply the same resources on the board if at all possible.

6.9 Definition of Modulation Rate and Frequency in the SSCG Specification

The SSCG circuit can be used to decrease the peak value of electromagnetic interference noise by frequency modulation, i.e. by slightly modulating the output frequency. In this case, the rate of change in the frequency and the size of the change to the input clock frequency are defined as the modulation rate and modulation frequency, respectively. Figure 6.4 shows the modulation rate and modulation frequency.

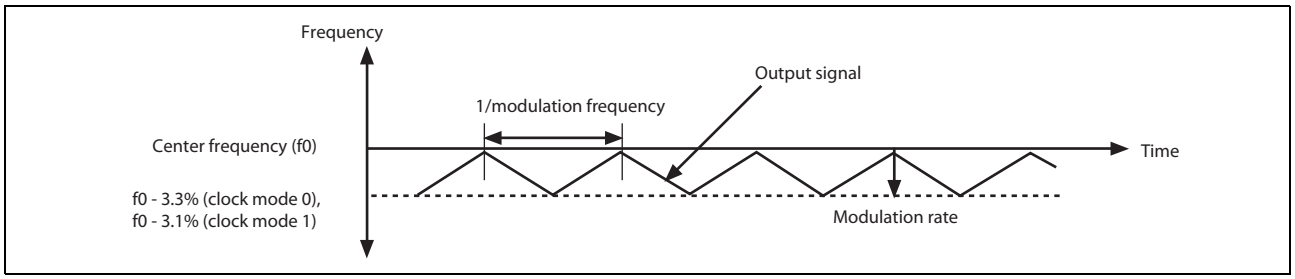

Figure 6.4 Definition of SSCG Modulation Rate and Frequency

6.11 Usage Note

6.11.1 Notes on the SSCG

When the SSCG is to be used, secure the SSCG stabilizing time (t_{SSCG}) shown in Table 47.5, Clock Timing in section 47, Electrical Characteristics. Furthermore, avoid deep standby while the SSCG is in use.

7. Interrupt Controller

The interrupt controller ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The interrupt controller registers set the order of priority of each interrupt, allowing the user to process interrupt requests according to the user-set priority.

7.1 Features

- 32 levels of interrupt priority can be set.
  By setting the interrupt priority registers, the priorities of IRQ interrupts, on-chip peripheral module interrupts, and pin interrupts can be selected from 32 levels for request sources.
- NMI noise canceler function
  An NMI input-level bit indicates the NMI pin state. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as the noise canceler function.
- Arm PrimeCell® generic interrupt controller (PL390)*

Note: * The PL390 supports version 1 of the specification for the architecture of the Arm generic interrupt controller (GIC).

Figure 7.1 shows a block diagram.

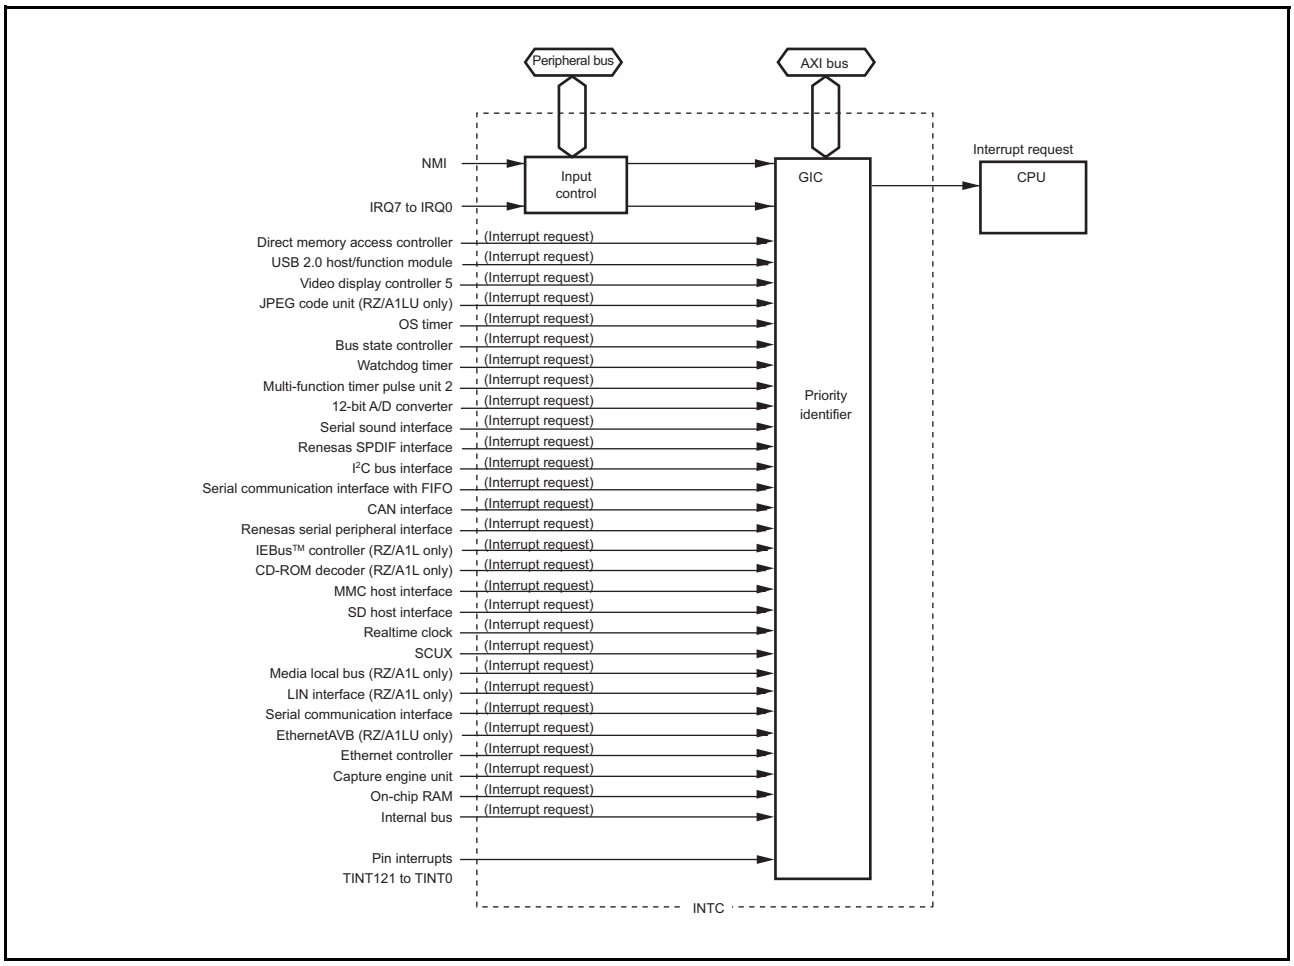

Figure 7.1 Block Diagram

7.2 Input/Output Pins

Table 7.1 shows the pin configuration.

Table 7.1 Pin Configuration

Pin Name	Symbol	I/O	Function
Nonmaskable interrupt input pin	NMI	Input	Input of nonmaskable interrupt request signal
Interrupt request input pins	IRQ7 to IRQ0	Input	Input of maskable interrupt request signals
	TINT121 to TINT0	Input	Input of maskable interrupt request signals

7.3 Register Descriptions

Table 7.2 shows the register configuration. These registers are used to set the interrupt priorities and control detection of the external interrupt input signal.

For a description of the registers other than interrupt control register 0, interrupt control register 1, and IRQ interrupt request register, see the Arm Generic Interrupt Controller Architecture Specification and the PrimeCell® Generic Interrupt Controller (PL390) Technical Reference Manual from Arm.

Table 7.2 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size

CPU interface implementer identification register	ICCIIDR	R	H'3901043B	H'E82020FC	32

Note 1. When the NMI pin is high, becomes H'8000; when low, becomes H'0000.
Note 2. Only 0 can be written after reading 1, to clear the flag.
Note 3. Use the following expression to calculate the maximum number of interrupt IDs from the number of IT lines.
(17+1) × 32 + 1 to (17 + 2) × 32: 577 to 608

7.3.1 Interrupt Control Register 0 (ICR0)

ICR0 is a 16-bit register that sets the input signal detection mode for the external interrupt input pin NMI, and indicates the input level at the NMI pin.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NMIL	-	-	-	-	-	-	NMIE	-	-	-	-	-	-	NMIF	-
Initial value:	*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/(W)*2	R

Notes: 1. 1 when the NMI pin is high, and 0 when the NMI pin is low.
2. Only 0 can be written after reading 1, to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15	NMIL	*1	R	NMI Input Level Sets the level of the signal input at the NMI pin. The NMI pin level can be obtained by reading this bit. This bit cannot be modified. 0: Low level is input to NMI pin 1: High level is input to NMI pin
14 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	NMIE	0	R/W	NMI Edge Select Selects whether the falling or rising edge of the interrupt request signal on the NMI pin is detected. 0: Interrupt request is detected on falling edge of NMI input 1: Interrupt request is detected on rising edge of NMI input
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	NMIF	0	R/(W)*2	NMI Interrupt Request This bit indicates the status of the NMI interrupt request. This bit cannot be modified. 0: NMI interrupt request has not occurred [Clearing conditions] • Cleared by changing NMIE of ICR0 • Cleared by reading NMIF while NMIF = 1, then writing 0 to NMIF 1: NMI interrupt request is detected [Setting condition] • Edge corresponding to NMIE of ICR0 has occurred at NMI pin
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

7.3.2 Interrupt Control Register 1 (ICR1)

ICR1 is a 16-bit register that specifies the detection mode for external interrupt input pins IRQ7 to IRQ0 individually: low level, falling edge, rising edge, or both edges.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ71S	IRQ70S	IRQ61S	IRQ60S	IRQ51S	IRQ50S	IRQ41S	IRQ40S	IRQ31S	IRQ30S	IRQ21S	IRQ20S	IRQ11S	IRQ10S	IRQ01S	IRQ00S
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	IRQ71S	0	R/W	IRQ Sense Select These bits select whether interrupt signals corresponding to pins IRQ7 to IRQ0 are detected by a low level, falling edge, rising edge, or both edges. 00: Interrupt request is detected on low level of IRQn input 01: Interrupt request is detected on falling edge of IRQn input 10: Interrupt request is detected on rising edge of IRQn input 11: Interrupt request is detected on both edges of IRQn input
14	IRQ70S	0	R/W	
13	IRQ61S	0	R/W	
12	IRQ60S	0	R/W	
11	IRQ51S	0	R/W	
10	IRQ50S	0	R/W	
9	IRQ41S	0	R/W	
8	IRQ40S	0	R/W	
7	IRQ31S	0	R/W	
6	IRQ30S	0	R/W	
5	IRQ21S	0	R/W	
4	IRQ20S	0	R/W	
3	IRQ11S	0	R/W	
2	IRQ10S	0	R/W	
1	IRQ01S	0	R/W	
0	IRQ00S	0	R/W	

[Legend]
n = 7 to 0

7.3.3 IRQ Interrupt Request Register (IRQRR)

IRQRR is a 16-bit register that indicates interrupt requests from external input pins IRQ7 to IRQ0. If edge detection is set for the IRQ7 to IRQ0 interrupts, writing 0 to the IRQ7F to IRQ0F bits after reading IRQ7F to IRQ0F = 1 cancels the retained interrupts.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	IRQ7F	IRQ6F	IRQ5F	IRQ4F	IRQ3F	IRQ2F	IRQ1F	IRQ0F
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*

Note: * Only 0 can be written to clear the flag after 1 is read.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	IRQ7F	0	R/(W)*	IRQ Interrupt Request These bits indicate the status of the IRQ7 to IRQ0 interrupt requests. Level detection: 0: IRQn interrupt request has not occurred [Clearing condition] • IRQn input is high 1: IRQn interrupt has occurred [Setting condition] • IRQn input is low Edge detection: 0: IRQn interrupt request is not detected [Clearing condition] • Cleared by reading IRQnF while IRQnF = 1, then writing 0 to IRQnF 1: IRQn interrupt request is detected [Setting condition] • Edge corresponding to IRQn1S or IRQn0S of ICR1 has occurred at IRQn pin
6	IRQ6F	0	R/(W)*	
5	IRQ5F	0	R/(W)*	
4	IRQ4F	0	R/(W)*	
3	IRQ3F	0	R/(W)*	
2	IRQ2F	0	R/(W)*	
1	IRQ1F	0	R/(W)*	
0	IRQ0F	0	R/(W)*	

[Legend]
n = 7 to 0

7.4 Interrupt Sources

There are four types of interrupt sources: NMI, IRQ, on-chip peripheral modules, and pin interrupts. Each interrupt has a priority level (0 to 31), with 0 the highest and 31 the lowest.

7.4.1 NMI Interrupt

The NMI interrupt with the highest priority is accepted by the CPU as an FIQ exception all times. NMI interrupt requests are edge-detected, and the NMI edge select bit (NMIE) in ICR0 selects whether the rising edge or falling edge is detected. The status of the interrupt request can be checked by reading the NMI interrupt request bit (NMIF) in the ICR0. When the NMIE bit is changed, the NMI interrupt request that is retained is cleared.
When deep standby mode is entered, deep standby mode is canceled by the NMI interrupt.

7.4.2 IRQ Interrupts

IRQ interrupts are input from pins IRQ7 to IRQ0. For the IRQ interrupts, low-level, falling-edge, rising-edge, or both-edge detection can be selected individually for each pin by the IRQ sense select bits (IRQ71S to IRQ01S and IRQ70S to IRQ00S) in interrupt control register 1 (ICR1).
When using low-level sensing for IRQ interrupts, an interrupt request signal is sent to the interrupt controller while the IRQ7 to IRQ0 pins are low. An interrupt request signal is stopped being sent to the interrupt controller when the IRQ7 to IRQ0 pins are driven high. The status of the interrupt requests can be checked by reading the IRQ interrupt request bits (IRQ7F to IRQ0F) in the IRQ interrupt request register (IRQRR).
When using edge-sensing for IRQ interrupts, an interrupt request is detected due to change of the IRQ7 to IRQ0 pin states, and an interrupt request signal is sent to the interrupt controller. The result of IRQ interrupt request detection is retained until that interrupt request is accepted. Whether IRQ interrupt requests have been detected or not can be checked by reading the IRQ7F to IRQ0F bits in the IRQ interrupt request register (IRQRR). Writing 0 to these bits after reading them as 1 clears the result of IRQ interrupt request detection.
When returning from IRQ interrupt exception service routine, execute the return instruction after confirming that the interrupt request has been cleared by the IRQ interrupt request register (IRQRR) so as not to accidentally receive the interrupt request again.

7.4.3 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following on-chip peripheral modules:

- Direct memory access controller
- USB 2.0 host/function module
- Video display controller 5
- JPEG codec unit (RZ/A1LU only)
- OS timer
- Bus state controller
- Watchdog timer
- Multi-function timer pulse unit 2
- 12-bit A/D converter
- Serial sound interface
- Renesas SPDIF interface
- I^2C bus interface
- Serial communication interface with FIFO
- CAN interface
- Renesas serial peripheral interface
- IEBus™ controller (RZ/A1L only)
- CD-ROM decoder (RZ/A1L only)
- MMC host interface
- SD host interface
- Realtime clock
- SCUX
- Media local bus (RZ/A1L only)
- LIN interface (RZ/A1L only)
- Serial communication interface
- EthernetAVB (RZ/A1LU only)
- Ethernet controller
- Capture engine unit
- On-chip RAM
- Internal bus

When returning from the interrupt exception service routine for an interrupt request at the peripheral-module level, execute the return instruction after clearing the source flag at the source of the request and reading the source flag so that the interrupt request is not accidentally received again.

7.4.4 Pin Interrupts

Pin interrupts are input from pins TINT121 to TINT0. Signals input on pins TINT121 to TINT0 are conveyed as interrupt signals regardless of mode settings and pin function settings for the general-purpose I/O port pin. Accordingly, if pin interrupts are to be used in port mode, set the pin as an input port pin. Alternatively, if an alternative mode is selected, the alternative pin with an input function can only be used for pin interrupts. For the settings of general-purpose I/O port pins, see section 41., Ports.

For the pin interrupts, high-level or rising-edge detection can be selected individually for each pin by the interrupt configuration registers (ICDICFRn). For a description of the interrupt configuration registers (ICDICFRn), see the GIC architecture specification.

7.5 Interrupt IDs

Table 7.3 lists the interrupt sources and their interrupt IDs, and the registers for setting the interrupt sources. Do not make settings other than those in table 7.3, otherwise, the operation cannot be guaranteed.
Each interrupt source is allocated a different interrupt ID. To control notification of the interrupt source to the CPU and reference its status, it is necessary to set and reference the following registers which correspond to given interrupt IDs.

- Interrupt security register ICDISRn
- Interrupt set-enable register ICDISERn
- Interrupt clear-enable register ICDICERn
- Interrupt set-pending register ICDISPRn
- Interrupt clear-pending register ICDICPRn
- Active bit register ICDABRn
- Interrupt configuration register ICDICFRn
- Interrupt priority register ICDIPRn
- Interrupt processor target register ICDIPTRn

For the procedure for the initial settings of the registers, see section 7.6.1 Initial Settings. For details on individual registers, see the Arm Generic Interrupt Controller Architecture Specification and the PrimeCell® Generic Interrupt Controller (PL390) Technical Reference Manual from Arm.

7.6 Operation

7.6.1 Initial Settings

For details on the registers for making initial settings and the procedures for settings in general, see the Arm Generic Interrupt Controller Architecture Specification and the PrimeCell® Generic Interrupt Controller (PL390) Technical Reference Manual from Arm. Figure 7.2 illustrates the flow of initial settings.

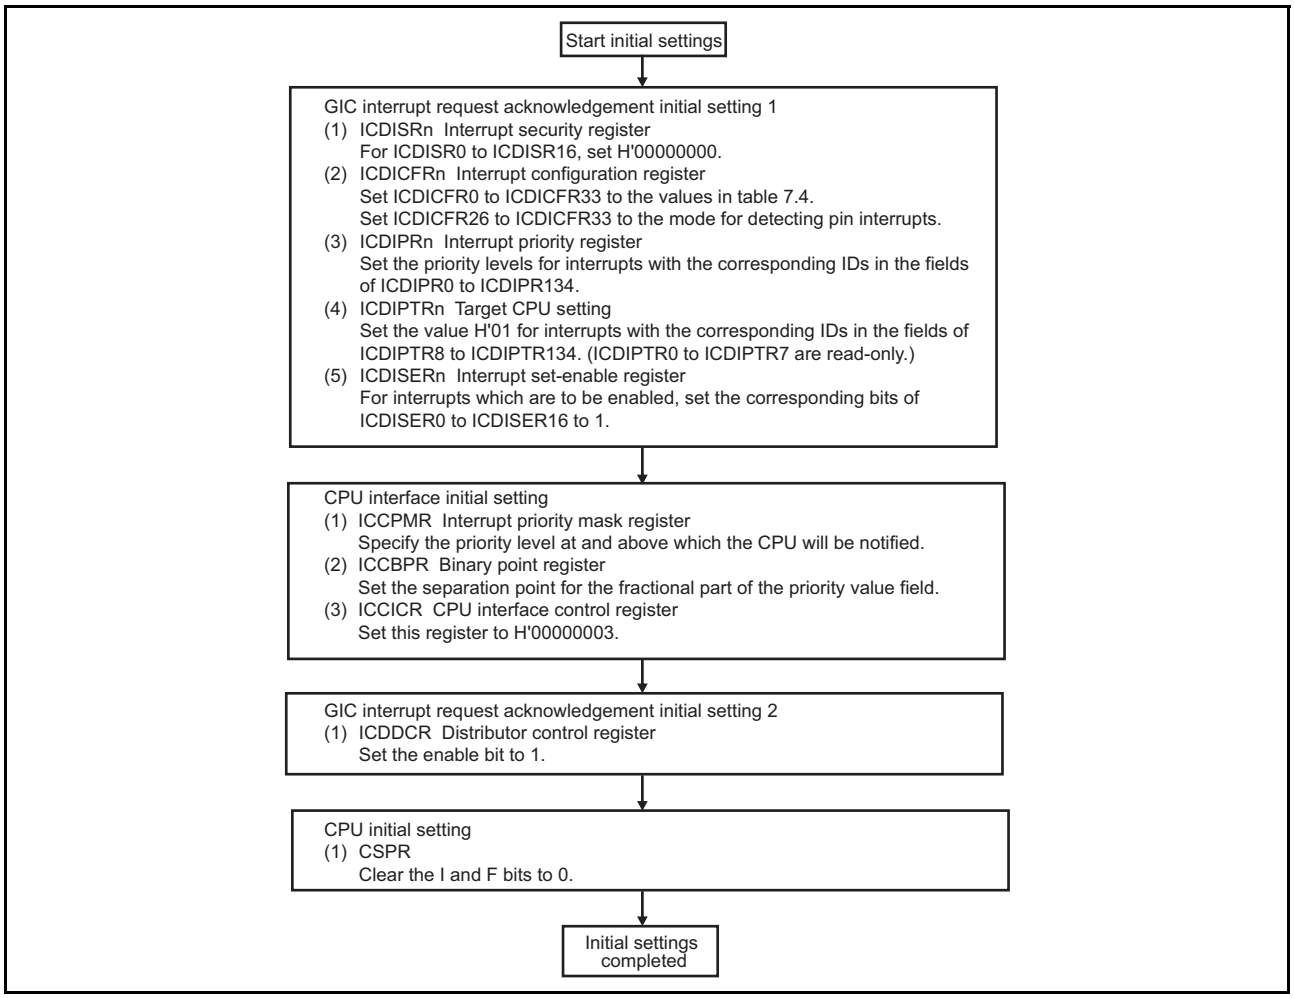

Figure 7.2 Flow of Initial Settings

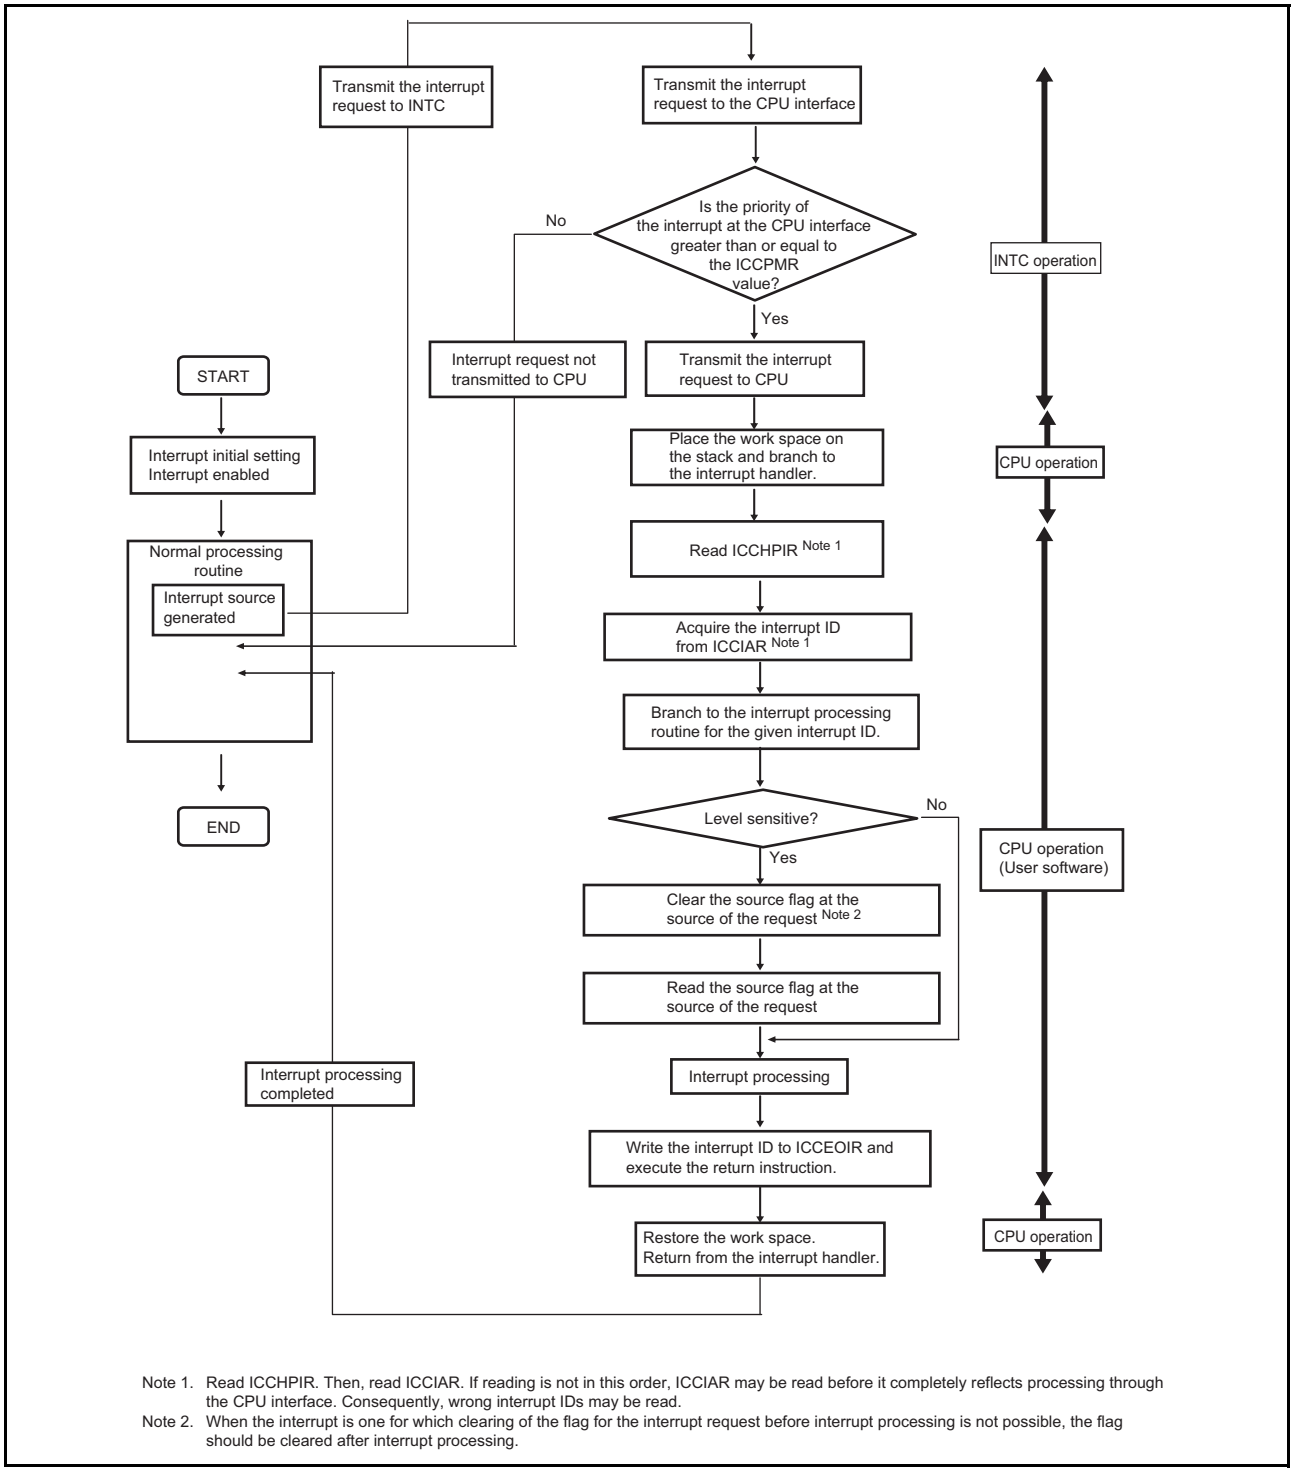
Table 7.4 ICDICFRn Interrupt Configuration Register Settings

Register Name	Setting	Interrupt ID
ICDICFR0	H'AAAAAAAA	15 to 0
ICDICFR1	H'00000055	31 to 16
ICDICFR2	H'FFFD5555	47 to 32
ICDICFR3	H'555FFFFF	63 to 48
ICDICFR4	H'55555555	79 to 64
ICDICFR5	H'55555555	95 to 80
ICDICFR6	H'55555555	111 to 96
ICDICFR7	H'55555555	127 to 112
ICDICFR8	H'5555F555	143 to 128
ICDICFR9	H'55555555	159 to 144
ICDICFR10	H'55555555	175 to 160
ICDICFR11	H'F5555555	191 to 176
ICDICFR12	H'F555F555	207 to 192
ICDICFR13	H'5555F555	223 to 208
ICDICFR14	H'55555555	239 to 224
ICDICFR15	H'55555555	255 to 240
ICDICFR16	H'55555555	271 to 256
ICDICFR17	H'FD555555	287 to 272
ICDICFR18	H'55555557	303 to 288
ICDICFR19	H'55555555	319 to 304
ICDICFR20	H'7FD55555	335 to 320
ICDICFR21	H'5F555555	351 to 336
ICDICFR22	H'FD55555F	367 to 352
ICDICFR23	H'55555557	383 to 368
ICDICFR24	H'55555555	399 to 384
ICDICFR25	H'55555555	415 to 400
ICDICFR26*1	H'55555555	431 to 416
ICDICFR27*1	H'55555555	447 to 432
ICDICFR28*1	H'55555555	463 to 448
ICDICFR29*1	H'55555555	479 to 464
ICDICFR30*1	H'55555555	495 to 480
ICDICFR31*1	H'55555555	511 to 496
ICDICFR32*1	H'55555555	527 to 512
ICDICFR33*1	H'55555555	537 to 528

Note 1. Edge or level detection can be selected for IDs corresponding to pin interrupts. The settings in the above table select level detection.

7.6.2 Flow of Interrupt Operations

For details on operation involved in interrupt generation, see the ArmGeneric Interrupt Controller Architecture Specification and the PrimeCell® Generic Interrupt Controller (PL390) Technical Reference Manual from Arm. Figure 7.3 shows the flow of interrupt operations.



Note 1. Read ICCHPIR. Then, read ICCIAR. If reading is not in this order, ICCIAR may be read before it completely reflects processing through the CPU interface. Consequently, wrong interrupt IDs may be read.
Note 2. When the interrupt is one for which clearing of the flag for the interrupt request before interrupt processing is not possible, the flag should be cleared after interrupt processing.

Figure 7.3 Flow of Interrupt Operations

7.7 Data Transfer with Interrupt Request Signals

Interrupt request signals can be used to activate the direct memory access controller and transfer data.
Interrupt sources for which the direct memory access controller is designated as the destination by DMA extension resource selectors 0 to 7 are masked and requests from them are not input to the interrupt controller.
Figure 7.4 shows a block diagram of interrupt control. For details, see section 9, Direct Memory Access Controller.

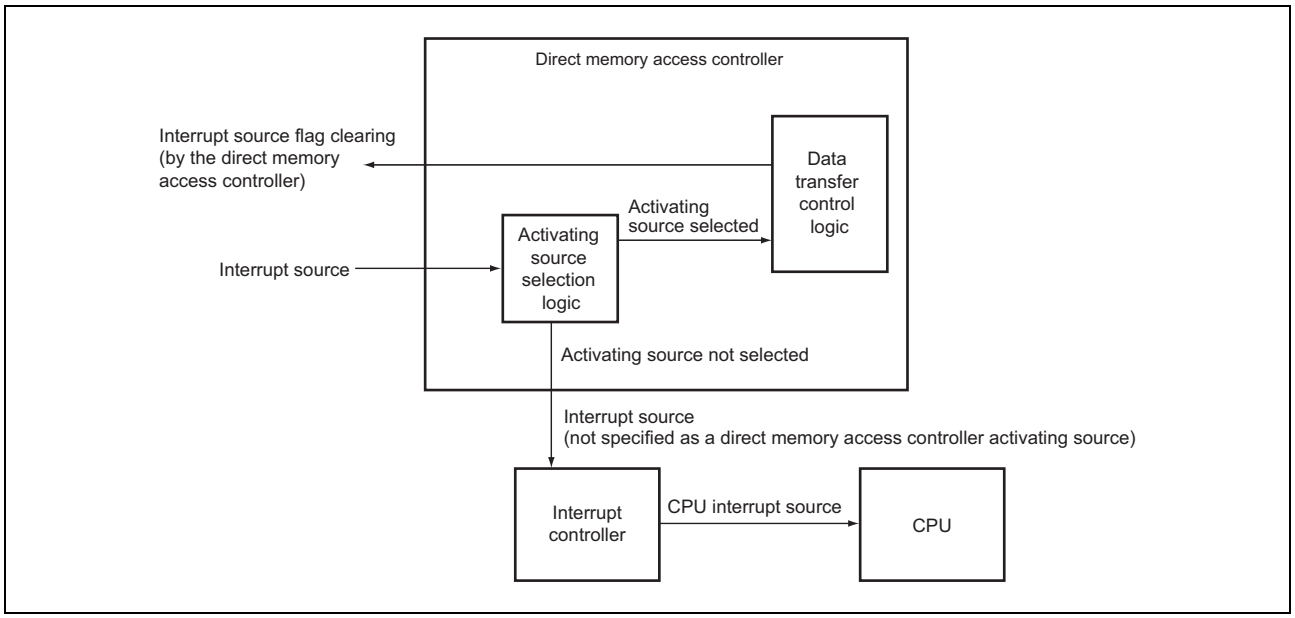


Figure 7.4 Interrupt Control Block Diagram

7.7.1 Handling Interrupt Request Signals as Sources for CPU Interrupt but Not Direct Memory Access Controller Activating

1. Do not select direct memory access controller activating sources.
2. When interrupts occur, interrupt requests are sent to the CPU.
3. The CPU clears the interrupt source and performs the necessary processing in the interrupt exception service routine.

7.7.2 Handling Interrupt Request Signals as Sources for Activating Direct Memory Access Controller but Not CPU Interrupt

1. Select direct memory access controller activating sources.
2. Activating sources are applied to the direct memory access controller when interrupts occur.
3. The direct memory access controller clears the interrupt sources when starting transfer.

7.8 Usage Note

7.8.1 Timing to Clear Interrupt Source

Clear the interrupt source flag to 0 in the interrupt exception handler. It takes some time to clear an interrupt in the CPU after clearing the interrupt source flag to 0. Read the interrupt source flag after clearing it to ensure that the interrupt request that should have been cleared is not received again erroneously. After that, execute the return instruction.

7.8.2 Notes on Selecting IRQ Interrupt Pin Functions

While the corresponding setting in interrupt control register 1 (ICR1) is for interrupt requests to be detected on falling edges or both edges of an IRQn input and the current input on the pin is at the low level, this will be detected as a falling edge and thus an interrupt when the pin function is switched to the IRQ interrupt function.

7.8.3 Notes on Reading Interrupt ID Values from Interrupt Acknowledge Register (ICCIAR)

If an interrupt ID value read from the interrupt acknowledge register (ICCIAR) is 0, the interrupt notice may be wrong. At that time, confirm the interrupt state before proceeding with interrupt processing.
When the interrupt ID is read as 0, the interrupt state can be confirmed by using bit 0 in the active bit register 0 (ICDABR0).

If the interrupt state is inactive, the interrupt notice is wrong and no interrupt processing is required.
Return from interrupt processing after writing the same value as the setting value to the interrupt priority register 0 (ICDIPR0).
If the interrupt state is active, the interrupt notice is correct. Proceed with interrupt processing.
If an interrupt ID value read from the interrupt acknowledge register (ICCIAR) is 1022 or 1023, return from interrupt processing after writing the same value as the setting value to the interrupt priority register 0 (ICDIPR0).

7.8.4 Notes on Using IRQ Pins as Triggers for Release from Standby when Software Standby is in Use

To use an IRQ pin as the trigger for release from standby when software standby is in use, execute the following processing.

(1) When the mode setting for an IRQ pin has been switched from the alternative mode to the port mode

Set the IRQ sense select bits corresponding to the given IRQ pin in interrupt control register 1 (ICR1) to the initial value, 00 (interrupt requests being detected as the low level of the IRQn input).

(2) When the mode setting for an IRQ pin has been switched from the port mode to the alternative mode

After switching the pin mode setting, make the setting of the IRQ sense select bits corresponding to the given IRQ pin in the following sequence. To start with, set the IRQ sense select bits in interrupt control register 1 (ICR1) to the initial value, 00 (interrupt requests being detected as the low level of the IRQn input), and then set them to the desired value, as described below.

- When the IRQ pin is to be used with the IRQ sense select bits set to 01 (interrupt requests being detected on falling edges of the IRQn input)
  Set these bits to 00 (detection as the low level) *1 and then to 01 (detection on falling edges).
- When the IRQ pin is to be used with the IRQ sense select bits set to 10 (interrupt requests being detected on rising edges of the IRQn input)
  Set these bits to 00 (detection as the low level) *1 and then to 10 (detection on rising edges).
- When the IRQ pin is to be used with the IRQ sense select bits set to 11 (interrupt requests being detected on the both edges of the IRQn input)
  Set these bits to 00 (detection as the low level) *1 and then to 11 (detection on the both edges).

Note 1. This setting is for the detection of interrupt requests when the IRQ pin is at the low level. Make the appropriate settings so that the interrupt function does not operate, i.e. the interrupt is ignored, during the period from setting of the IRQ pin mode to setting of the IRQ sense select bits.

8. Bus State Controller

The bus state controller outputs control signals for various types of memory and external devices that are connected to the external address space. The functions of this module enable this LSI to connect directly with SRAM, SDRAM, and other memory storage devices, and external devices.

8.1 Features

1. External address space
   —A maximum of 64 Mbytes for each of areas CS0 to CS5.
   —Can specify the normal space interface, SRAM interface with byte selection, burst ROM (clocked synchronous or asynchronous), MPX-I/O, and SDRAM memory type for each address space.
   —Can select the data bus width (8, 16, or 32 bits) for each of address spaces.
   —Controls insertion of wait cycles for each address space.
   —Controls insertion of wait cycles for each read access and write access.
   —Can set independent idle cycles during the continuous access for five cases: read-write (in same space/different spaces), read-read (in same space/different spaces), the first cycle is a write access.
2. Normal space interface
   —Supports the interface that can directly connect to the SRAM.
3. Burst ROM interface (clocked asynchronous)
   —High-speed access to the ROM that has the page mode function.
4. MPX-I/O interface
   —Can directly connect to a peripheral LSI that needs an address/data multiplexing.
5. SDRAM interface
   —Can set the SDRAM in up to two areas.
   —Multiplex output for row address/column address.
   —Efficient access by single read/single write.
   —High-speed access in bank-active mode.
   —Supports an auto-refresh and self-refresh.
   —Supports a power-down mode.
   —Issues MRS and EMRS commands.
6. SRAM interface with byte selection
   —Can connect directly to a SRAM with byte selection.
7. Burst ROM interface (clocked synchronous)
   —Can connect directly to a burst ROM of the clocked synchronous type.
8. Refresh function
   —Supports the auto-refresh and self-refresh functions.
   —Specifies the refresh interval using the refresh counter and clock selection.
   —Can execute concentrated refresh by specifying the refresh counts (1, 2, 4, 6, or 8).
9. Usage as interval timer for refresh counter
   —Generates an interrupt request at compare match.
10. Detection of long wait state for access by the signal on the external $\overline{\text{WAIT}}$ pin.
    —A timeout detection condition is specifiable per CS space.
    —Once timeout is detected, the external WAIT function is disabled and a timeout detection interrupt request is issued.

Figure 8.1 shows a block diagram of this module.

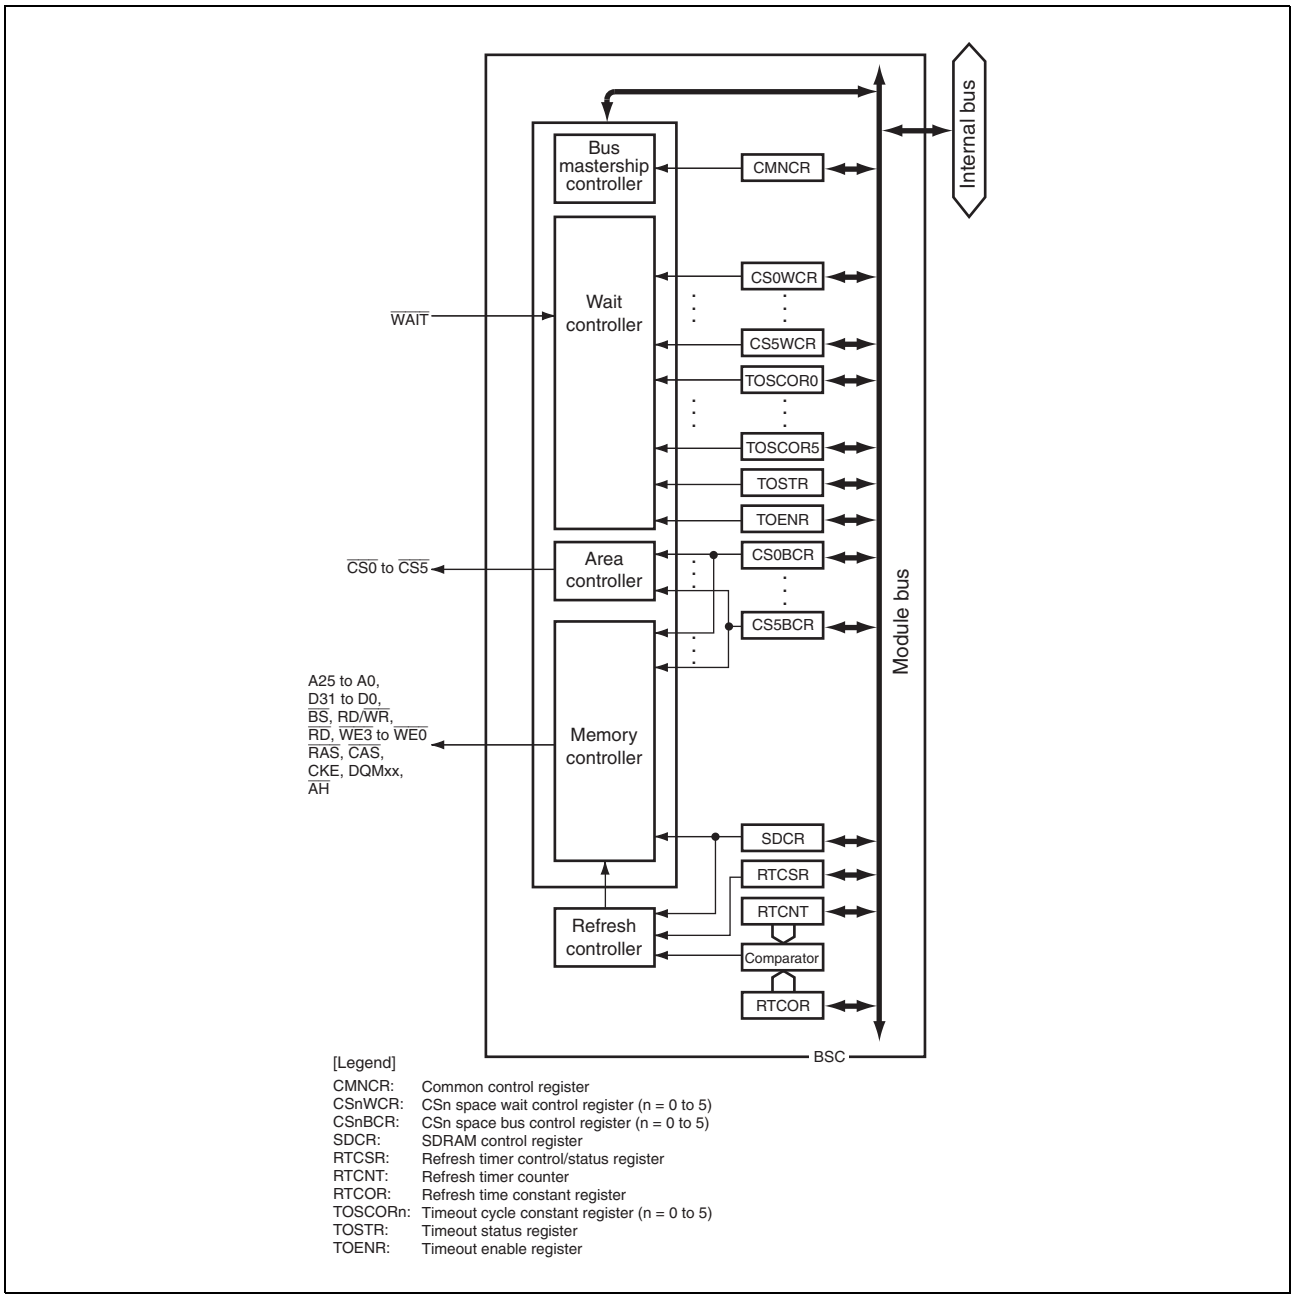

Figure 8.1 Block Diagram of Bus State Controller

8.2 Input/Output Pins

Table 8.1 shows the pin configuration.

Table 8.1 Pin Configuration

Name	I/O	Function
A25 to A0	Output	Address bus
D31 to D0	I/O	Data bus
$\overline{BS}$	Output	Bus cycle start
$\overline{CS0}$ to $\overline{CS5}$	Output	Chip select
RD/$\overline{WR}$	Output	Read/write Connects to $\overline{WE}$ pins when SDRAM or SRAM with byte selection is connected.
$\overline{RD}$	Output	Read pulse signal (read data output enable signal)
$\overline{WE3}$/DQMUU/$\overline{AH}$	Output	Indicates that D31 to D24 are being written to. Connected to the byte select signal when a SRAM with byte selection is connected. Functions as the select signals for D31 to D24 when SDRAM is connected. Functions as the address hold signal when the MPX-I/O is used.
$\overline{WE2}$/DQMUL	Output	Indicates that D23 to D16 are being written to. Connected to the byte select signal when a SRAM with byte selection is connected. Functions as the select signals for D23 to D16 when SDRAM is connected.
$\overline{WE1}$/DQMLU	Output	Indicates that D15 to D8 are being written to. Connected to the byte select signal when a SRAM with byte selection is connected. Functions as the select signals for D15 to D8 when SDRAM is connected.
$\overline{WE0}$/DQMLL	Output	Indicates that D7 to D0 are being written to. Connected to the byte select signal when a SRAM with byte selection is connected. Functions as the select signals for D7 to D0 when SDRAM is connected.
$\overline{RAS}$	Output	Connects to $\overline{RAS}$ pin when SDRAM is connected.
$\overline{CAS}$	Output	Connects to $\overline{CAS}$ pin when SDRAM is connected.
CKE	Output	Connects to CKE pin when SDRAM is connected.
$\overline{WAIT}$	Input	External wait input

8.3 Area Overview

8.3.1 Address Map

In the architecture, this LSI has a 32-bit address space, which is divided into external memory spaces (SPI multi I/O bus space, large-capacity on-chip RAM, hold on-chip RAM, on-chip peripheral modules, and reserved areas) according to the upper bits of the address.
See section 5, LSI Internal Bus (including Secondary Cache) for how to enable or disable caching for the CS0 to CS5 external address spaces.
The kind of memory to be connected and the data bus width are specified in each partial space. The address map for the external address space is listed below.

Table 8.2 Address Map

Internal Address	Space	Memory to be Connected
H'00000000 to H'03FFFFFF	CS0	Normal space, SRAM with byte selection, burst ROM (asynchronous or synchronous)
H'04000000 to H'07FFFFFF	CS1	Normal space, SRAM with byte selection
H'08000000 to H'0BFFFFFF	CS2	Normal space, SRAM with byte selection, SDRAM
H'0C000000 to H'0FFFFFFF	CS3	Normal space, SRAM with byte selection, SDRAM
H'10000000 to H'13FFFFFF	CS4	Normal space, SRAM with byte selection, burst ROM (asynchronous)
H'14000000 to H'17FFFFFF	CS5	Normal space, SRAM with byte selection, MPX-I/O
H'18000000 to H'3FFFFFFF	Other	SPI multi I/O bus space, large-capacity on-chip RAM, hold on-chip RAM, on-chip peripheral modules, reserved area*1
H'40000000 to H'407FFFFF	CS0 mirror	Access from the north main bus is not possible, but access from the south main bus is possible.*2
H'40800000 to H'43FFFFFF	CS0 mirror	Normal space, SRAM with byte selection, burst ROM (asynchronous or synchronous)
H'44000000 to H'47FFFFFF	CS1 mirror	Normal space, SRAM with byte selection
H'48000000 to H'4BFFFFFF	CS2 mirror	Normal space, SRAM with byte selection, SDRAM
H'4C000000 to H'4FFFFFFF	CS3 mirror	Normal space, SRAM with byte selection, SDRAM
H'50000000 to H'53FFFFFF	CS4 mirror	Normal space, SRAM with byte selection, burst ROM (asynchronous)
H'54000000 to H'57FFFFFF	CS5 mirror	Normal space, SRAM with byte selection, MPX-I/O
H'58000000 to H'FFFFFFFF	Other	SPI multi I/O bus space (mirror), large-capacity on-chip RAM (mirror), hold on-chip RAM (mirror), on-chip peripheral modules, reserved area*1

Note 1. For the large-capacity on-chip RAM space and hold on-chip RAM space, access the addresses shown in section 40, On-Chip RAM. For the on-chip peripheral module space, access the addresses shown in section 46, List of Registers. Do not access addresses which are not described in these sections. Otherwise, the correct operation cannot be guaranteed.
Note 2. For details, see section 5, LSI Internal Bus.

8.3.2 Data Bus Width and Related Pin Setting for Each Area Depending on Boot Mode

The initial state of data bus width and settings of the pins related to this module depends on boot mode. For boot mode, refer to section 3, Boot Mode.

In boot mode 0, the state of area 0 is fixed to the state with bus width of 16 bits, because this LSI is started up by the program stored in the ROM connected to area 0. The initial states of areas 1 to 5 are the same as that of area 0, but the bus width can be changed by the program. Immediately after a power-on reset in these modes, some of the address and data-bus signals and the $\overline{CS0}$, $\overline{RD}$, and RD/$\overline{WR}$ signals are automatically selected by default as the functions of the corresponding pins, since these signals are required to read ROM data from area 0. With the exception of these pins, the general purpose pin function is selected by default, and other required pin functions must be specified by the program. Read access to area 0 is only permitted before the pin settings are completed.

In boot modes 1 to 3, the state of areas 0 to 5 can be changed from the initial state by the program, because the LSI is started by the program stored in the SPI serial memory, the NAND flash memory with the SD controller, or the NAND flash memory with the MMC controller. Since pin functions related to this module are not set automatically, they need to be set by the program. Do not access external address spaces before the pin settings are completed.

Table 8.3 shows the initial state by areas 0 to 5 in boot modes 0 and 1 to 3.

The sample access waveforms shown in this section include the pins such as $\overline{BS}$ and $\overline{WEn}$. They are the waveforms when pin functions are assigned to the general I/O ports. For example, when 16-bit bus width is used, setting for pin A1 is needed. When 8-bit bus width is used, setting for pins A1 and A0 is also needed.

For details on pin function settings, see section 41, Ports.

Table 8.3 Initial States by Areas in Boot Modes 0 and 1 to 3

Boot Mode	Item	Area 0	Areas 1 to 5
0	Data bus width	Fixed to 16 bits. Not changeable.	16 bits. Can be changed by program.
	Settings of pins related to this module	Pins A20 to A1, D15 to D0, $\overline{CS0}$, RD/$\overline{WR}$, and $\overline{RD}$ are set automatically. Other pins need to be set by program.	
1 to 3	Data bus width	32 bits. Can be changed by program.	
	Settings of pins related to this module	General I/O function. For external bus access, all the necessary pins need to be set by program.	

Note 1. If operation is to start in boot mode 0 and the connected boot ROM includes address bit A21 or higher-order address bits, the circuit board must include pull-down resistors for the corresponding address lines.

Note 2. The data-bus width may be limited by the type of memory in use. For details, see section 8.4.2, CSn Space Bus Control Register (CSnBCR) (n = 0 to 5).

8.4 Register Descriptions

Table 8.4 shows the register configuration of this module.
Do not access the areas until settings of the connected memory interface are completed.

Table 8.4 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Common control register	CMNCR	R/W	H'00001018	H'3FFFC000	32
CS0 space bus control register	CS0BCR	R/W	H'36DB0C00*1	H'3FFFC004	32
CS1 space bus control register	CS1BCR	R/W	H'36DB0C00*1	H'3FFFC008	32
CS2 space bus control register	CS2BCR	R/W	H'36DB0C00*1	H'3FFFC00C	32
CS3 space bus control register	CS3BCR	R/W	H'36DB0C00*1	H'3FFFC010	32
CS4 space bus control register	CS4BCR	R/W	H'36DB0C00*1	H'3FFFC014	32
CS5 space bus control register	CS5BCR	R/W	H'36DB0C00*1	H'3FFFC018	32
CS0 space wait control register	CS0WCR	R/W	H'00000500	H'3FFFC028	32
CS1 space wait control register	CS1WCR	R/W	H'00000500	H'3FFFC02C	32
CS2 space wait control register	CS2WCR	R/W	H'00000500	H'3FFFC030	32
CS3 space wait control register	CS3WCR	R/W	H'00000500	H'3FFFC034	32
CS4 space wait control register	CS4WCR	R/W	H'00000500	H'3FFFC038	32
CS5 space wait control register	CS5WCR	R/W	H'00000500	H'3FFFC03C	32
SDRAM control register	SDCR	R/W	H'00000000	H'3FFFC04C	32
Refresh timer control/status register	RTCSR	R/W	H'00000000	H'3FFFC050	32
Refresh timer counter	RTCNT	R/W	H'00000000	H'3FFFC054	32
Refresh time constant register	RTCOR	R/W	H'00000000	H'3FFFC058	32
Timeout cycle constant register 0	TOSCOR0	R/W	H'00000000	H’3FFFC060	32
Timeout cycle constant register 1	TOSCOR1	R/W	H'00000000	H’3FFFC064	32
Timeout cycle constant register 2	TOSCOR2	R/W	H'00000000	H’3FFFC068	32
Timeout cycle constant register 3	TOSCOR3	R/W	H'00000000	H’3FFFC06C	32
Timeout cycle constant register 4	TOSCOR4	R/W	H'00000000	H’3FFFC070	32
Timeout cycle constant register 5	TOSCOR5	R/W	H'00000000	H’3FFFC074	32
Timeout status register	TOSTR	R/W	H’00000000	H’3FFFC080	32
Timeout enable register	TOENR	R/W	H’00000000	H’3FFFC084	32

Note 1. H'36DB0C00 in boot mode 0; H'36DB0E00 in boot modes 1 to 3

8.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the common items for each area.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	TL0	-	-	-	AL0	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	DPRTY[1:0]		-	-	-	-	-	-	-	HIZ MEM	HIZ CNT*
Initial value:	0	0	0	1	0	0	0	0	0	0	0	1	1	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	TL0	0	R/W	Transfer End Level Specifies the TEND0 signal output is high active or low active. 0: Low-active output from TEND0 1: High-active output from TEND0
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	AL0	0	R/W	Specifies the DACK0 (acknowledge) signal output is high active or low active. 0: Low-active output from DACK0 1: High-active output from DACK0
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10, 9	DPRTY[1:0]	00	R/W	DMA Burst Transfer Priority Specify the priority for a refresh request during DMA burst transfer. 0*: Accepts a refresh request during DMA burst transfer. 10: Does not accept a refresh request during DMA burst transfer. 11: Reserved (setting prohibited)
8 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4, 3	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	HIZMEM	0	R/W	High-Z Memory Control Specifies the pin state in software standby mode or deep standby mode for A25 to A0, $\overline{BS}$, $\overline{CSn}$, RD/$\overline{WR}$, $\overline{WEn}$/DQMxx/$\overline{AH}$, and $\overline{RD}$. 0: High impedance in software standby mode or deep standby mode. 1: Driven in software standby mode or deep standby mode
0	HIZCNT*	0	R/W	High-Z Control Specifies the state in software standby mode or deep standby mode for CKE, $\overline{RAS}$, and $\overline{CAS}$. 0: High impedance in software standby mode or deep standby mode for CKE, $\overline{RAS}$, and $\overline{CAS}$. 1: Driven in software standby mode or deep standby mode for CKE, $\overline{RAS}$, and $\overline{CAS}$.

Note: * For High-Z control of CKIO, see section 6, Clock Pulse Generator.

8.4.2 CSn Space Bus Control Register (CSnBCR) (n = 0 to 5)

CSnBCR is a 32-bit readable/writable register that specifies the memory connected to each space, the number of idle cycles between bus cycles, and the bus width.

Do not access external memory for the corresponding area until CSnBCR initial setting and pin setting are completed. Idle cycles may be inserted even when they are not specified. For details, see section 8.5.10, Wait between Access Cycles.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	IWW[2:0]			IWRWD[2:0]			IWRWS[2:0]			IWRRD[2:0]			IWRRS[2:0]

R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	TYPE[2:0]			-	BSZ[1:0]		-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	1	1*	0*	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R	R	R

Note: * B'10 in boot mode 0; B'11 in boot modes 1 to 3.

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	IWW[2:0]	011	R/W	Idle Cycles between Write-Read Cycles and Write-Write Cycles These bits specify the number of idle cycles to be inserted after the access to a memory that is connected to the space. The target access cycles are the write-read cycle and write-write cycle. 000: No idle cycle inserted 001: 1 idle cycle inserted 010: 2 idle cycles inserted 011: 4 idle cycles inserted 100: 6 idle cycles inserted 101: 8 idle cycles inserted 110: 10 idle cycles inserted 111: 12 idle cycles inserted
27 to 25	IWRWD[2:0]	011	R/W	Idle Cycles for Another Space Read-Write Specify the number of idle cycles to be inserted after the access to a memory that is connected to the space. The target access cycle is a read-write one in which continuous access cycles switch between different spaces. 000: No idle cycle inserted 001: 1 idle cycle inserted 010: 2 idle cycles inserted 011: 4 idle cycles inserted 100: 6 idle cycles inserted 101: 8 idle cycles inserted 110: 10 idle cycles inserted 111: 12 idle cycles inserted
24 to 22	IWRWS[2:0]	011	R/W	Idle Cycles for Read-Write in the Same Space Specify the number of idle cycles to be inserted after the access to a memory that is connected to the space. The target cycle is a read-write cycle of which continuous access cycles are for the same space. 000: No idle cycle inserted 001: 1 idle cycle inserted 010: 2 idle cycles inserted 011: 4 idle cycles inserted 100: 6 idle cycles inserted 101: 8 idle cycles inserted 110: 10 idle cycles inserted 111: 12 idle cycles inserted

Bit	Bit Name	Initial Value	R/W	Description
21 to 19	IWRRD[2:0]	011	R/W	Idle Cycles for Read-Read in Another Space Specify the number of idle cycles to be inserted after the access to a memory that is connected to the space. The target cycle is a read-read cycle of which continuous access cycles switch between different space. 000: No idle cycle inserted 001: 1 idle cycle inserted 010: 2 idle cycles inserted 011: 4 idle cycles inserted 100: 6 idle cycles inserted 101: 8 idle cycles inserted 110: 10 idle cycles inserted 111: 12 idle cycles inserted
18 to 16	IWRRS[2:0]	011	R/W	Idle Cycles for Read-Read in the Same Space Specify the number of idle cycles to be inserted after the access to a memory that is connected to the space. The target cycle is a read-read cycle of which continuous access cycles are for the same space. 000: No idle cycle inserted 001: 1 idle cycle inserted 010: 2 idle cycles inserted 011: 4 idle cycles inserted 100: 6 idle cycles inserted 101: 8 idle cycles inserted 110: 10 idle cycles inserted 111: 12 idle cycles inserted
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	TYPE[2:0]	000	R/W	Specify the type of memory connected to a space. 000: Normal space 001: Burst ROM (clock asynchronous) 010: MPX-I/O 011: SRAM with byte selection 100: SDRAM 101: Reserved (setting prohibited) 110: Reserved (setting prohibited) 111: Burst ROM (clock synchronous) For details for memory type in each area, see Table 8.2. Note: When connecting the burst ROM to the CS0 space in boot mode 0, change the CS0WCR register to the settings by the burst ROM CS0WCR uses and then set TYPE[2:0] to the burst ROM setting. In boot modes 1 to 3, memory access should be performed after setting CS0BCR and CS0WCR.
11	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
10, 9	BSZ[1:0]	10*	R/W	Data Bus Width Specification Specify the data bus widths of spaces. 00: Reserved (setting prohibited) 01: 8-bit size 10: 16-bit size 11: 32-bit size For MPX-I/O, selects bus width by address Notes: 1. If area 5 is specified as MPX-I/O, the bus width can be specified as 8 bits or 16 bits by the address according to the SZSEL bit in CS5WCR by specifying the BSZ[1:0] bits to 11. The fixed bus width can be specified as 8 bits or 16 bits 2. In boot modes 0, the BSZ[1:0] bits settings in CS0BCR are ignored. 3. If area 2 or area 3 is specified as SDRAM space, the bus width can be specified as either 16 bits or 32 bits. 4. If area 0 is specified as clocked synchronous burst ROM space, the bus width can be specified as either 16 bits or 32 bits.
8 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * B'10 in boot mode 0; B'11 in boot modes 1 to 3.

8.4.3 CSn Space Wait Control Register (CSnWCR) (n = 0 to 5)

CSnWCR specifies various wait cycles for memory access. The bit configuration of this register varies as shown below according to the memory type (TYPE2 to TYPE0) specified by the CSn space bus control register (CSnBCR). Specify CSnWCR before accessing the target area. Specify CSnBCR first, then specify CSnWCR.

(1) Normal Space, SRAM with Byte Selection, and MPX-I/O

- CS0WCR

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	—*	0	R/W	Reserved Set this bit to 0 when the interfaces for normal space or for SRAM with byte selection are used.
20	BAS	0	R/W	SRAM with Byte Selection Byte Access Select Specifies the $\overline{WEn}$ and RD/$\overline{WR}$ signal timing when the SRAM interface with byte selection is used. 0: Asserts the $\overline{WEn}$ signal at the read/write timing and asserts the RD/$\overline{WR}$ signal during the write access cycle. 1: Asserts the $\overline{WEn}$ signal during the read/write access cycle and asserts the RD/$\overline{WR}$ signal at the write timing.
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	—*	All 0	R/W	Reserved Set these bits to 0 when the interfaces for normal space or for SRAM with byte selection are used.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12, 11	SW[1:0]	00	R/W	Number of Delay Cycles from Address, $\overline{CS0}$ Assertion to $\overline{RD}$, $\overline{WEn}$ Assertion Specify the number of delay cycles from address and $\overline{CS0}$ assertion to $\overline{RD}$ and $\overline{WEn}$ assertion. 00: 0.5 cycles 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

Bit	Bit Name	Initial Value	R/W	Description
10 to 7	WR[3:0]	1010	R/W	Number of Access Wait Cycles Specify the number of cycles that are necessary for read/write access. 0000: No cycle 0001: 1 cycle 0010: 2 cycles 0011: 3 cycles 0100: 4 cycles 0101: 5 cycles 0110: 6 cycles 0111: 8 cycles 1000: 10 cycles 1001: 12 cycles 1010: 14 cycles 1011: 18 cycles 1100: 24 cycles 1101: Reserved (setting prohibited) 1110: Reserved (setting prohibited) 1111: Reserved (setting prohibited)
6	WM	0	R/W	External Wait Mask Specification Specifies whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycle is 0. 0: External wait input is valid 1: External wait input is ignored
5 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	HW[1:0]	00	R/W	Delay Cycles from $\overline{RD}$, $\overline{WEn}$ Negation to Address, $\overline{CS0}$ Negation Specify the number of delay cycles from $\overline{RD}$ and $\overline{WEn}$ negation to address and $\overline{CS0}$ negation. 00: 0.5 cycles 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

Note: * In boot mode 0, to connect the burst ROM to the CS0 space and switch to burst ROM interface after activation, set the TYPE[2:0] bits in CS0BCR after setting the burst number by the bits 20 and 21 and the burst wait cycle number by the bits 16 and 17. Do not write 1 to the reserved bits other than above bits.

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	SZSEL	0	R/W	MPX-I/O Interface Bus Width Specification Specifies an address to select the bus width when the BSZ[1:0] of CS5BCR are specified as 11. This bit is valid only when area 5 is specified as MPX-I/O. 0: Selects the bus width by address A14 1: Selects the bus width by address A21 The relationship between the SZSEL bit and bus width selected by A14 or A21 are summarized below.
20	MPXW	0	R/W	MPX-I/O Interface Address Wait This bit setting is valid only when area 5 is specified as MPX-I/O. Specifies the address cycle insertion wait for MPX-I/O interface. 0: Inserts no wait cycle 1: Inserts 1 wait cycle
20	BAS	0	R/W	SRAM with Byte Selection Byte Access Select This bit setting is valid only when area 5 is specified as SRAM with byte selection. Specifies the $\overline{WEn}$ and RD/$\overline{WR}$ signal timing when the SRAM interface with byte selection is used. 0: Asserts the $\overline{WEn}$ signal at the read timing and asserts the RD/$\overline{WR}$ signal during the write access cycle. 1: Asserts the $\overline{WEn}$ signal during the read access cycle and asserts the RD/$\overline{WR}$ signal at the write timing.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	WW[2:0]	000	R/W	Number of Write Access Wait Cycles Specify the number of cycles that are necessary for write access. 000: The same cycles as WR[3:0] setting (number of read access wait cycles) 001: No cycle 010: 1 cycle 011: 2 cycles 100: 3 cycles 101: 4 cycles 110: 5 cycles 111: 6 cycles
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

SZSEL	A14	A21	Bus Width
0	0	Not affected	8 bits
0	1	Not affected	16 bits
1	Not affected	0	8 bits
1	Not affected	1	16 bits

Bit	Bit Name	Initial Value	R/W	Description
12, 11	SW[1:0]	00	R/W	Number of Delay Cycles from Address, $\overline{CS5}$ Assertion to $\overline{RD}$, $\overline{WE}$ Assertion Specify the number of delay cycles from address and $\overline{CS5}$ assertion to $\overline{RD}$ and $\overline{WEn}$ assertion when area 5 is specified as normal space or SRAM with byte selection. Specify the number of delay cycles from the end of address cycle (Ta3) to $\overline{RD}$ and $\overline{WEn}$ assertion when area 5 is specified as MPx-I/O. 00: 0.5 cycles 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles
10 to 7	WR[3:0]	1010	R/W	Number of Read Access Wait Cycles Specify the number of cycles that are necessary for read access. 0000: No cycle 0001: 1 cycle 0010: 2 cycles 0011: 3 cycles 0100: 4 cycles 0101: 5 cycles 0110: 6 cycles 0111: 8 cycles 1000: 10 cycles 1001: 12 cycles 1010: 14 cycles 1011: 18 cycles 1100: 24 cycles 1101: Reserved (setting prohibited) 1110: Reserved (setting prohibited) 1111: Reserved (setting prohibited)
6	WM	0	R/W	External Wait Mask Specification Specifies whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycle is 0. 0: External wait input is valid 1: External wait input is ignored
5 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	HW[1:0]	00	R/W	Delay Cycles from $\overline{RD}$, $\overline{WEn}$ Negation to Address, $\overline{CS5}$ Negation Specify the number of delay cycles from $\overline{RD}$ and $\overline{WEn}$ negation to address and $\overline{CS5}$ negation when area 5 is specified as normal space or SRAM with byte selection. Specify the number of delay cycles from $\overline{RD}$ and $\overline{WEn}$ negation to $\overline{CS5}$ negation when area 5 is specified as MPx-I/O. 00: 0.5 cycles 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

(2) Burst ROM (Clocked Asynchronous)

Note: * If both areas 2 and 3 are specified as SDRAM, WTRP[1:0], WTRCD[1:0], TRWL[1:0], and WTRC[1:0] bit settings are used in both areas in common.

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14, 13	WTRP[1:0]*	00	R/W	Number of Auto-Precharge Completion Wait Cycles Specify the number of minimum precharge completion wait cycles as shown below. • From the start of auto-precharge and issuing of ACTV command for the same bank • From issuing of the PRE/PALL command to issuing of the ACTV command for the same bank • Till entering the power-down mode or deep power-down mode • From the issuing of PALL command to issuing REF command in auto refresh mode • From the issuing of PALL command to issuing SELF command in self refresh mode The setting for areas 2 and 3 is common. 00: No cycle 01: 1 cycle 10: 2 cycles 11: 3 cycles
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
11, 10	WTRCD [1:0]*	01	R/W	Number of Wait Cycles between ACTV Command and READ(A)/WRIT(A) Command Specify the minimum number of wait cycles from issuing the ACTV command to issuing the READ(A)/WRIT(A) command. The setting for areas 2 and 3 is common. 00: No cycle 01: 1 cycle 10: 2 cycles 11: 3 cycles
9	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
8, 7	A3CL[1:0]	10	R/W	CAS Latency for Area 3 Specify the CAS latency for area 3. 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4, 3	TRWL[1:0]*	00	R/W	Number of Auto-Precharge Startup Wait Cycles Specify the number of minimum auto-precharge startup wait cycles as shown below. • Cycle number from the issuance of the WRITA command by this LSI until the completion of auto-precharge in the SDRAM. Equivalent to the cycle number from the issuance of the WRITA command until the issuance of the ACTV command. Confirm that how many cycles are required between the WRITA command receive in the SDRAM and the auto-precharge activation, referring to each SDRAM data sheet. And set the cycle number so as not to exceed the cycle number specified by this bit. • Cycle number from the issuance of the WRIT command until the issuance of the PRE command. This is the case when accessing another low address in the same bank in bank active mode. The setting for areas 2 and 3 is common. 00: No cycle 01: 1 cycle 10: 2 cycles 11: 3 cycles
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	WTRC[1:0]*	00	R/W	Number of Idle Cycles from REF Command/Self-Refresh Release to ACTV/REF/MRS Command Specify the number of minimum idle cycles in the periods shown below. • From the issuance of the REF command until the issuance of the ACTV/REF/MRS command • From releasing self-refresh until the issuance of the ACTV/REF/MRS command. The setting for areas 2 and 3 is common. 00: 2 cycles 01: 3 cycles 10: 5 cycles 11: 8 cycles

Note: * If both areas 2 and 3 are specified as SDRAM, WTRP[1:0], WTRCD[1:0], TRWL[1:0], and WTRC[1:0] bit settings are used in both areas in common.

If only one area is connected to the SDRAM, specify area 3. In this case, specify area 2 as normal space or SRAM with byte selection.

10 to 7	W[3:0]	1010	R/W	Number of Access Wait Cycles Specify the number of wait cycles to be inserted in the first access cycle. 0000: No cycle 0001: 1 cycle 0010: 2 cycles 0011: 3 cycles 0100: 4 cycles 0101: 5 cycles 0110: 6 cycles 0111: 8 cycles 1000: 10 cycles 1001: 12 cycles 1010: 14 cycles 1011: 18 cycles 1100: 24 cycles 1101: Reserved (setting prohibited) 1110: Reserved (setting prohibited) 1111: Reserved (setting prohibited)
6	WM	0	R/W	External Wait Mask Specification Specifies whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycle is 0. 0: External wait input is valid 1: External wait input is ignored
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

8.4.4 SDRAM Control Register (SDCR)

SDCR specifies the method to refresh and access SDRAM, and the types of SDRAMs to be connected.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	A2ROW[1:0]		-	A2COL[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	DEEP	-	RFSH	RMODE	PDOWN	BACTV	-	-	-	A3ROW[1:0]		-	A3COL[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20, 19	A2ROW[1:0]	00	R/W	Number of Bits of Row Address for Area 2 Specify the number of bits of row address for area 2. 00: 11 bits 01: 12 bits 10: 13 bits 11: Reserved (setting prohibited)
18	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
17, 16	A2COL[1:0]	00	R/W	Number of Bits of Column Address for Area 2 Specify the number of bits of column address for area 2. 00: 8 bits 01: 9 bits 10: 10 bits 11: Reserved (setting prohibited)
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	DEEP	0	R/W	Deep Power-Down Mode This bit is valid for low-power SDRAM. If the RFSH or RMODE bit is set to 1 while this bit is set to 1, the deep power-down entry command is issued and the low-power SDRAM enters the deep power-down mode. 0: Self-refresh mode 1: Deep power-down mode
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
11	RFSH	0	R/W	Refresh Control Specifies whether or not the refresh operation of the SDRAM is performed. 0: No refresh 1: Refresh
10	RMODE	0	R/W	Refresh Mode Specifies whether to perform auto-refresh or self-refresh when the RFSH bit is 1. When the RFSH bit is 1 and this bit is 1, self-refresh starts immediately. When the RFSH bit is 1 and this bit is 0, auto-refresh starts according to the contents that are set in registers RTCSR, RTCNT, and RTCOR. 0: Auto-refresh is performed 1: Self-refresh is performed

Bit	Bit Name	Initial Value	R/W	Description
9	PDOWN	0	R/W	Power-Down Mode Specifies whether the SDRAM will enter the power-down mode after the access to the SDRAM. With this bit being set to 1, after the SDRAM is accessed, the CKE signal is driven low and the SDRAM enters the power-down mode. 0: The SDRAM does not enter the power-down mode after being accessed. 1: The SDRAM enters the power-down mode after being accessed.
8	BACTV	0	R/W	Bank Active Mode Specifies to access whether in auto-precharge mode (using READA and WRITA commands) or in bank active mode (using READ and WRIT commands). 0: Auto-precharge mode (using READA and WRITA commands) 1: Bank active mode (using READ and WRIT commands) Note: Bank active mode can be set only for area 3. When both areas 2 and 3 are set to SDRAM, specify the auto-precharge mode.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4, 3	A3ROW[1:0]	00	R/W	Number of Bits of Row Address for Area 3 Specify the number of bits of the row address for area 3. 00: 11 bits 01: 12 bits 10: 13 bits 11: Reserved (setting prohibited)
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	A3COL[1:0]	00	R/W	Number of Bits of Column Address for Area 3 Specify the number of bits of the column address for area 3. 00: 8 bits 01: 9 bits 10: 10 bits 11: Reserved (setting prohibited)

8.4.5 Refresh Timer Control/Status Register (RTCSR)

RTCSR specifies various items about refresh for SDRAM.

When RTCSR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

The phase of the clock for incrementing the count in the refresh timer counter (RTCNT) is adjusted only by a power-on reset. Note that there is an error in the time until the compare match flag is set for the first time after the timer is started with the CKS[2:0] bits being set to a value other than B'000.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CMF	CMIE	CKS[2:0]			RRC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7	CMF	0	R/W	Compare Match Flag Indicates that a compare match occurs between the refresh timer counter (RTCNT) and refresh time constant register (RTCOR). This bit is set or cleared in the following conditions. 0: Clearing condition: When 0 is written in CMF after reading out RTCSR during CMF = 1. 1: Setting condition: When the condition RTCNT = RTCOR is satisfied.
6	CMIE	0	R/W	Compare Match Interrupt Enable Enables or disables CMF interrupt requests when the CMF bit in RTCSR is set to 1. 0: Disables CMF interrupt requests. 1: Enables CMF interrupt requests.
5 to 3	CKS[2:0]	000	R/W	Clock Select Select the clock input to count-up the refresh timer counter (RTCNT). 000: Stop the counting-up 001: CKIOφ/4 010: CKIOφ/16 011: CKIOφ/64 100: CKIOφ/256 101: CKIOφ/1024 110: CKIOφ/2048 111: CKIOφ/4096
2 to 0	RRC[2:0]	000	R/W	Refresh Count Specify the number of continuous refresh cycles, when the refresh request occurs after the coincidence of the values of the refresh timer counter (RTCNT) and the refresh time constant register (RTCOR). These bits can make the period of occurrence of refresh long. 000: 1 time 001: 2 times 010: 4 times 011: 6 times 100: 8 times 101: Reserved (setting prohibited) 110: Reserved (setting prohibited) 111: Reserved (setting prohibited)

8.4.6 Refresh Timer Counter (RTCNT)

RTCNT is an 8-bit counter that increments using the clock selected by bits CKS[2:0] in RTCSR. When RTCNT matches RTCOR, RTCNT is cleared to 0. The value in RTCNT returns to 0 after counting up to 255. When the RTCNT is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7 to 0		All 0	R/W	8-Bit Counter

8.4.7 Refresh Time Constant Register (RTCOR)

RTCOR is an 8-bit register. When RTCOR matches RTCNT, the CMF bit in RTCSR is set to 1 and RTCNT is cleared to 0.

When the RFSH bit in SDCR is 1, a memory refresh request is issued by this matching signal. This request is maintained until the refresh operation is performed. If the request is not processed when the next matching occurs, the previous request is ignored.

When the CMIE bit in RTCSR is set to 1, an interrupt request is issued by this matching signal. The request continues to be output until the CMF bit in RTCSR is cleared. Clearing the CMF bit only affects the interrupt request and does not clear the refresh request. Therefore, a combination of refresh request and interval timer interrupt can be specified so that the number of refresh requests are counted by using timer interrupts while refresh is performed periodically.

When RTCOR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 8	—	All 0	R	Reserved These bits are always read as 0.
7 to 0		All 0	R/W	8-Bit Counter

8.4.8 Timeout Cycle Constant Register (TOSCORn) (n = 0 to 5)

TOSCORn is a 16-bit register the value of which is effective when the WM bit in the CSn space wait control register (CSnWCR) is 0 and the corresponding bit in the timeout enable register (TOENR) is 1. When the number of cycles of waiting due to the signal on the eternal wait input pin matches the setting of TOSCORn, external wait input is disabled to end the cycle of access, the timeout status flag for the corresponding space in the timeout status register (TOSTR) is set, and a timeout detection interrupt request is generated. The timeout detection interrupt request is retained until the corresponding bit in TOENR is set to 0 or 0 is written to the timeout status flag for the corresponding space. Note that timeout detection is enabled even while the timeout status flag for the corresponding space in TOSTR is 1, and external wait input is disabled in response to a further timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0.
15 to 0		All 0	R/W	16-Bit Register H'0000: 65536 cycles H'0001: 1 cycle : H'FFFF: 65535 cycles

8.4.9 Timeout Status Register (TOSTR)

TOSTOR is an 8-bit register that holds the timeout status flags for the CS spaces. When the WM bit in the CSn space wait control register (CSnWCR) is 0 and the corresponding bit in the timeout enable register (TOENR) is 1 and the number of cycles of waiting in response to the signal on the eternal wait input matches the setting of TOSCORn, the timeout status flag for the corresponding space is set and a timeout detection interrupt request is generated. The only writable value for the timeout status flags is 0, which clears the flag. Writing 1 to a flag is ignored.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0.
5	CS5TOSTF	0	R/W	CS5 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS5 space has matched the setting of the CS5 space timeout cycle constant register (TOSCOR5).This bit is set or cleared in the following conditions. 0: Clearing condition When 0 is written in CS5TOSTF. 1: Setting condition When the WM bit in the CS5 space wait control register (CS5WCR) is 0 and the CS5TOEN bit in the timeout enable register (TOENR) is 1, the number of cycles of waiting due to the input on the external wait pin during access to the CS5 space has matched the setting of TOSCOR5.
4	CS4TOSTF	0	R/W	CS4 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS4 space has matched the setting of the CS4 space timeout cycle constant register (TOSCOR4). For the condition to set or clear this bit, refer to the description of CS5TOSTF.
3	CS3TOSTF	0	R/W	CS3 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS3 space has matched the setting of the CS3 space timeout cycle constant register (TOSCOR3). For the condition to set or clear this bit, refer to the description of CS5TOSTF.
2	CS2TOSTF	0	R/W	CS2 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS2 space has matched the setting of the CS2 space timeout cycle constant register (TOSCOR2). For the condition to set or clear this bit, refer to the description of CS5TOSTF.
1	CS1TOSTF	0	R/W	CS1 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS1 space has matched the setting of the CS1 space timeout cycle constant register (TOSCOR1). For the condition to set or clear this bit, refer to the description of CS5TOSTF.

Bit	Bit Name	Initial Value	R/W	Description
0	CS0TOSTF	0	R/W	CS0 Space Timeout Status Flag Status flag that indicates that the number of cycles of waiting due to the input on the external wait pin during access to the CS0 space has matched the setting of the CS0 space timeout cycle constant register (TOSCOR0). For the condition to set or clear this bit, refer to the description of CS5TOSTF.

8.4.10 Timeout Enable Register (TOENR)

TOENR is an 8-bit register that specifies enabling or disabling the detection of timeout for waiting in each of the CS spaces.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	CS5 TOEN	CS4 TOEN	CS3 TOEN	CS2 TOEN	CS1 TOEN	CS0 TOEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0.
5	CS5TOEN	0	R/W	CS5 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS5 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.
4	CS4TOEN	0	R/W	CS4 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS4 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.
3	CS3TOEN	0	R/W	CS3 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS3 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.
2	CS2TOEN	0	R/W	CS2 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS2 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.
1	CS1TOEN	0	R/W	CS1 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS1 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.
0	CS0TOEN	0	R/W	CS0 Space Timeout Detection Enable Specifies enabling or disabling the detection of timeout for waiting in the CS0 space. 0: The timeout detection is disabled. 1: The timeout detection is enabled.

8.5 Operation

8.5.1 Access Size and Data Alignment

This LSI supports little endian, in which the least significant byte (LSB) is that in the direction of the 0th address.
Data bus width can be selected from 8 bits, 16 bits, and 32 bits for the normal memory and SRAM with byte selection.
Data bus width can be selected from 16 bits and 32 bits for SDRAM. For MPX-I/O, the data bus width is fixed to either 8 or 16 bits, or made selectable as 8 bits or 16 bits by one of the address lines.
Data bus width varies depending on boot mode. For details, refer to section 8.3.2, Data Bus Width and Related Pin Setting for Each Area Depending on Boot Mode.
Data alignment is performed in accordance with the data bus width selected for the device. This also means that four read operations are required to read 32-bit data from a byte-width device. In this LSI, data alignment and conversion of data length is performed automatically between the respective interfaces.
Table 8.5 to Table 8.7 show the relationship between device data width and access unit.

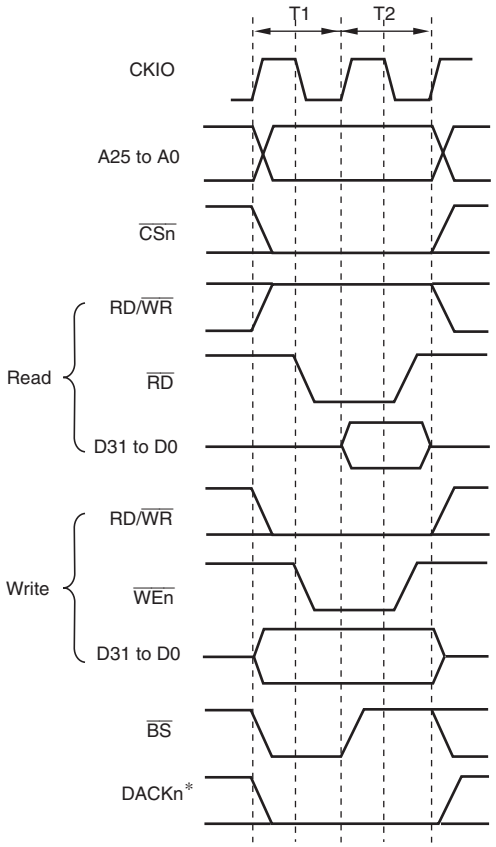
8.5.2 Normal Space Interface

(1) Basic Timing

For access to a normal space, this LSI uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. When using SRAM with a byte-selection pin, see section 8.5.8, SRAM Interface with Byte Selection. Figure 8.2 shows the basic timings of normal space access. A no-wait normal access is completed in two cycles. The $\overline{BS}$ signal is asserted for one cycle to indicate the start of a bus cycle.



Note: * The waveform for DACKn is when active low is specified.

Figure 8.2 Normal Space Basic Access Timing (Access Wait 0)

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 32 bits are always read in case of a 32-bit device. 16 bits are always read in case of a 16-bit device. When writing, only the $\overline{WEn}$ signal for the byte to be written is asserted.
It is necessary to output the data that has been read using $\overline{RD}$ when a buffer is established in the data bus. The RD/$\overline{WR}$ signal is in a read state (high output) when no access has been carried out. Therefore, care must be taken when controlling the external data buffer with this signal, to avoid output collision.
Figure 8.3 and Figure 8.4 show the basic timings in continuous access to normal space. If the WM bit in CSnWCR is cleared to 0, a Tnop cycle is inserted after the CSn space access to evaluate the external wait (Figure 8.3). If the WM bit in CSnWCR is set to 1, external waits are ignored and no Tnop cycle is inserted (Figure 8.4).

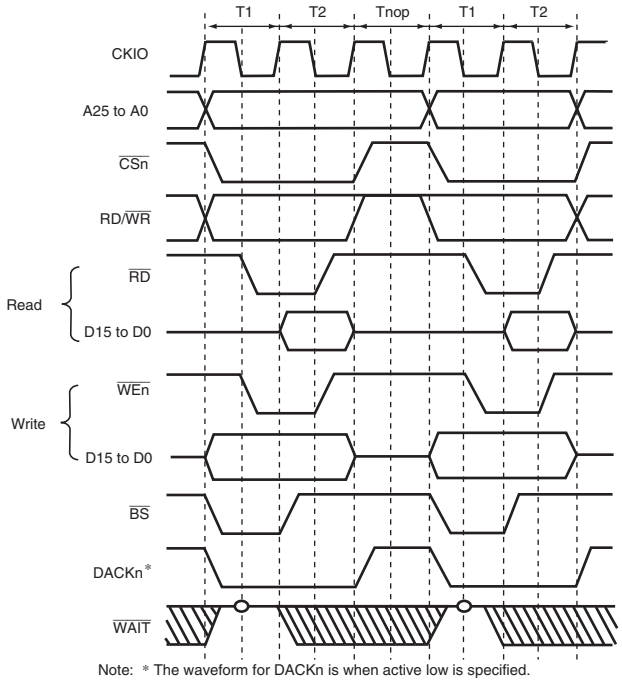


Figure 8.3 Continuous Access to Normal Space (1) Bus Width = 16 Bits, 32-Bit Access, CSnWCR.WM Bit = 0 (Access Wait = 0, Cycle Wait = 0)

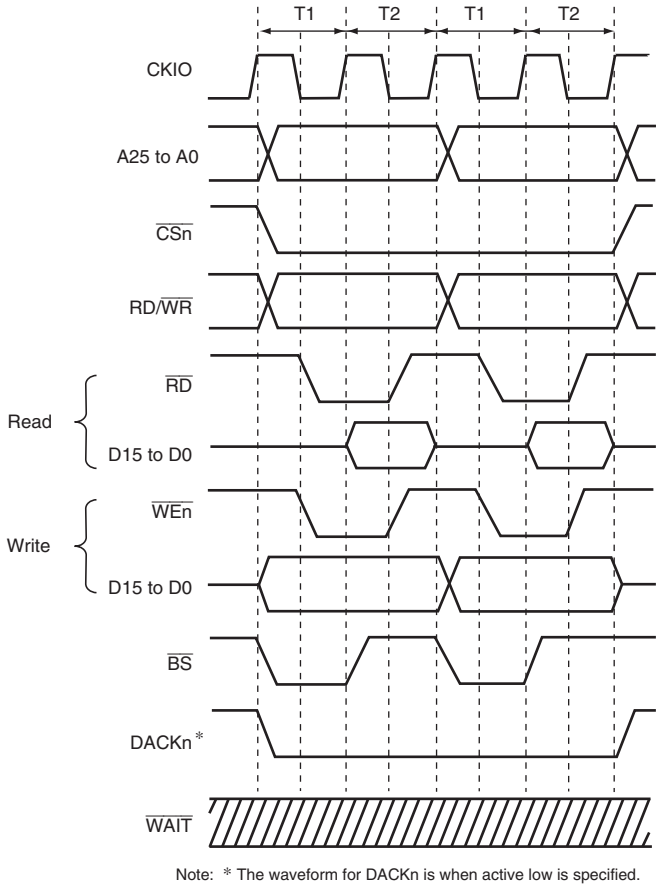

Figure 8.4 Continuous Access to Normal Space (2) Bus Width = 16 Bits, 32-Bit Access, CSnWCR.WM Bit = 1 (Access Wait = 0, Cycle Wait = 0)

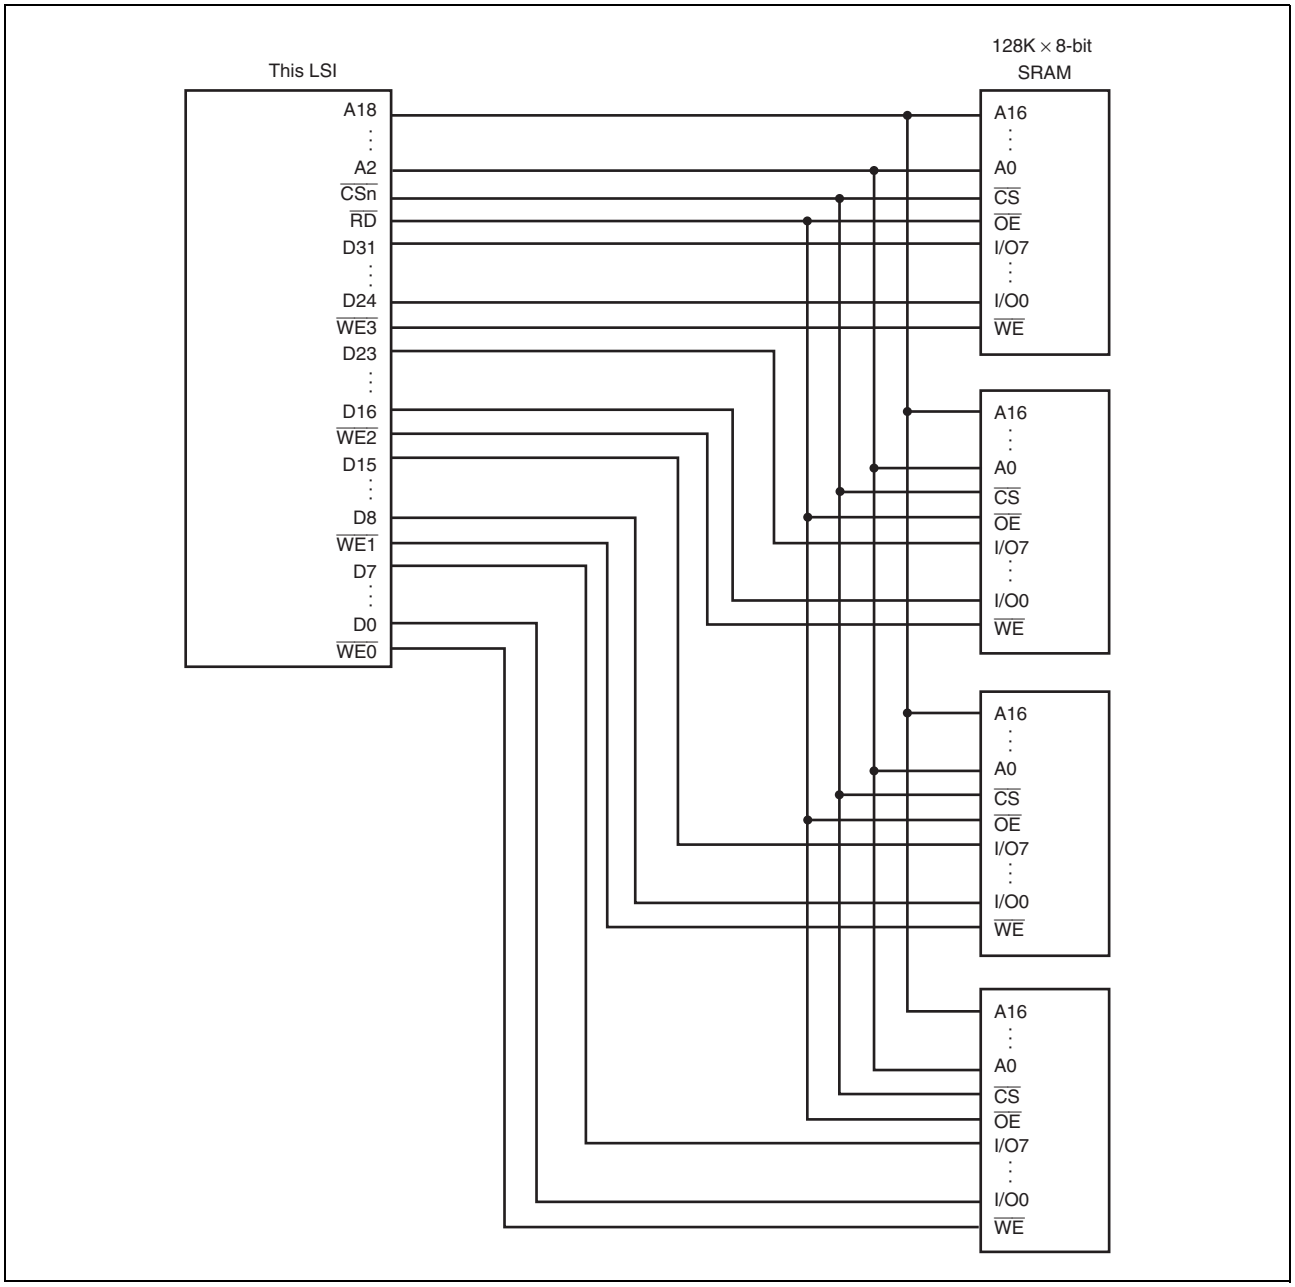

Figure 8.5 Example of 32-Bit Data-Width SRAM Connection

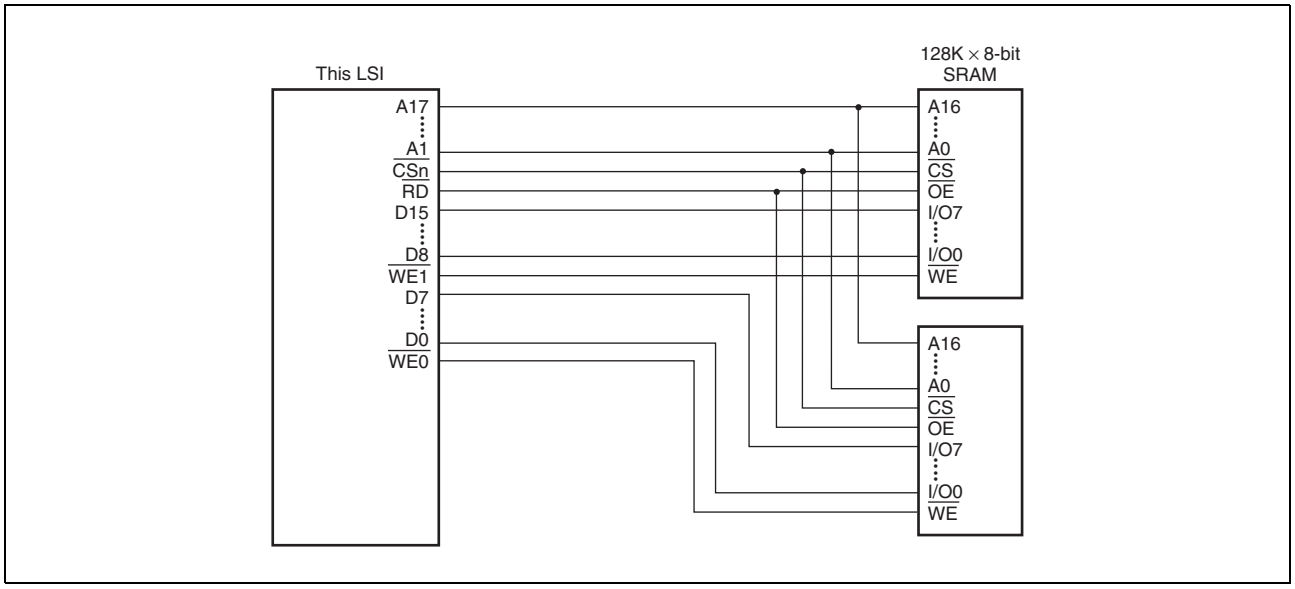

Figure 8.6 Example of 16-Bit Data-Width SRAM Connection

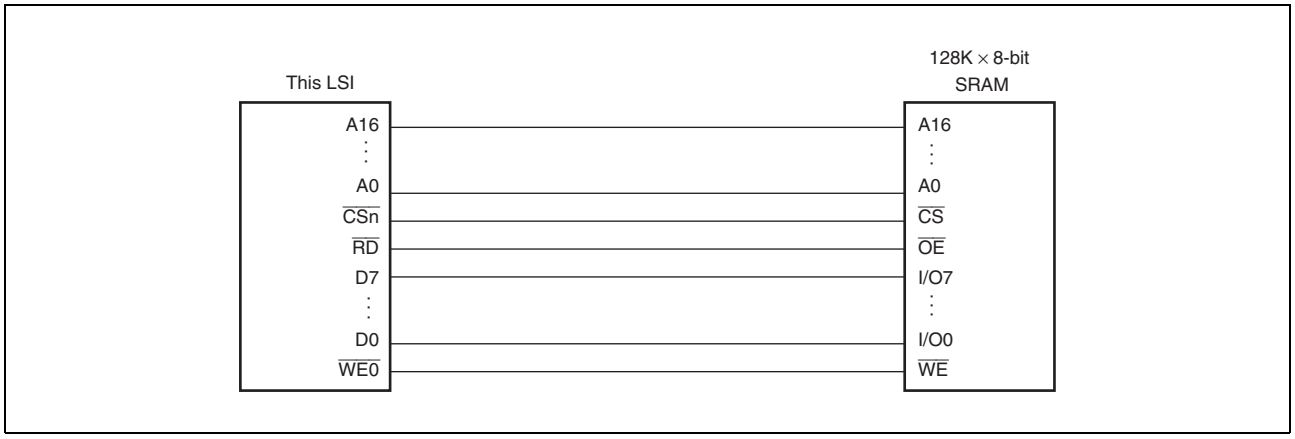

Figure 8.7 Example of 8-Bit Data-Width SRAM Connection

8.5.3 Access Wait Control

Wait cycle insertion on a normal space access can be controlled by the settings of bits WR3 to WR0 in CSnWCR. It is possible for areas 1, 4, and 5 to insert wait cycles independently in read access and in write access. Areas 0, 2, and 3 have common access wait for read cycle and write cycle. The specified number of Tw cycles are inserted as wait cycles in a normal space access shown in Figure 8.8.

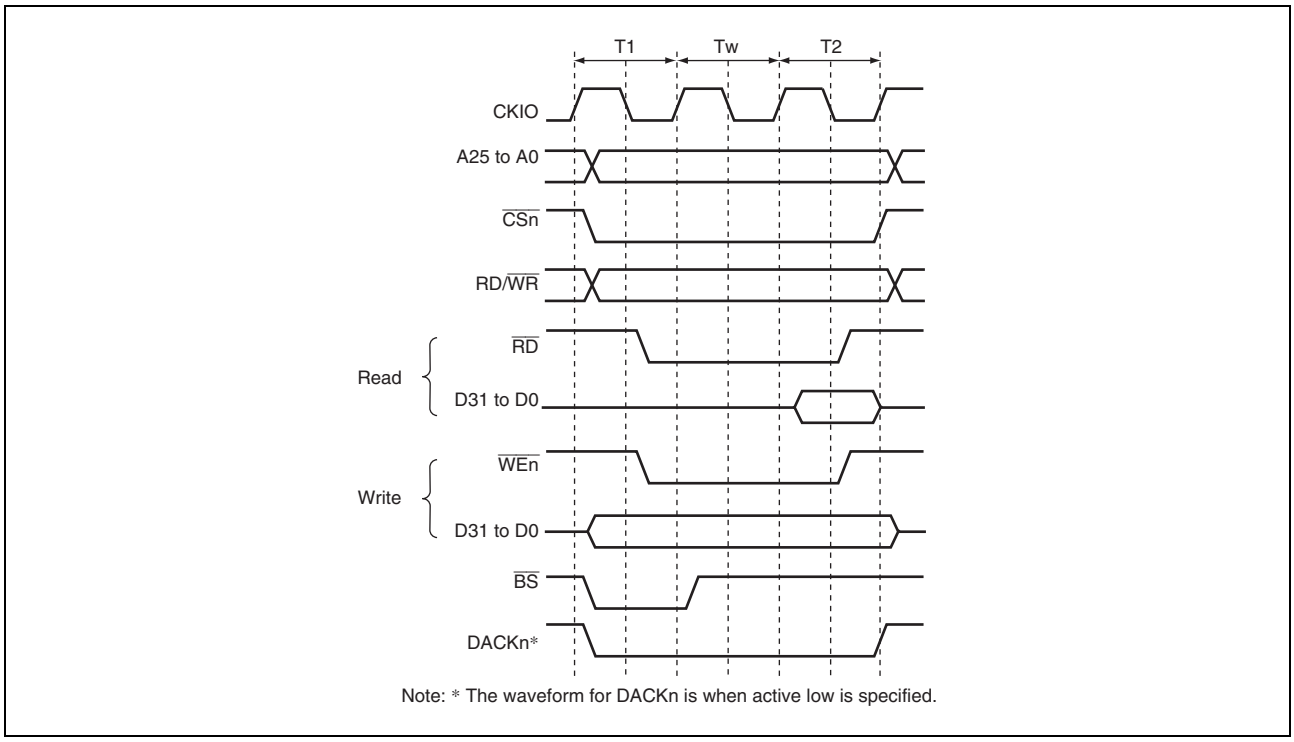

Figure 8.8 Wait Timing for Normal Space Access (Software Wait Only)

When the WM bit in CSnWCR is cleared to 0, the external wait input $\overline{\text{WAIT}}$ signal is also sampled. $\overline{\text{WAIT}}$ pin sampling is shown in Figure 8.9. A 2-cycle wait is specified as a software wait. The $\overline{\text{WAIT}}$ signal is sampled on the falling edge of CKIO at the transition from the T1 or Tw cycle to the T2 cycle.

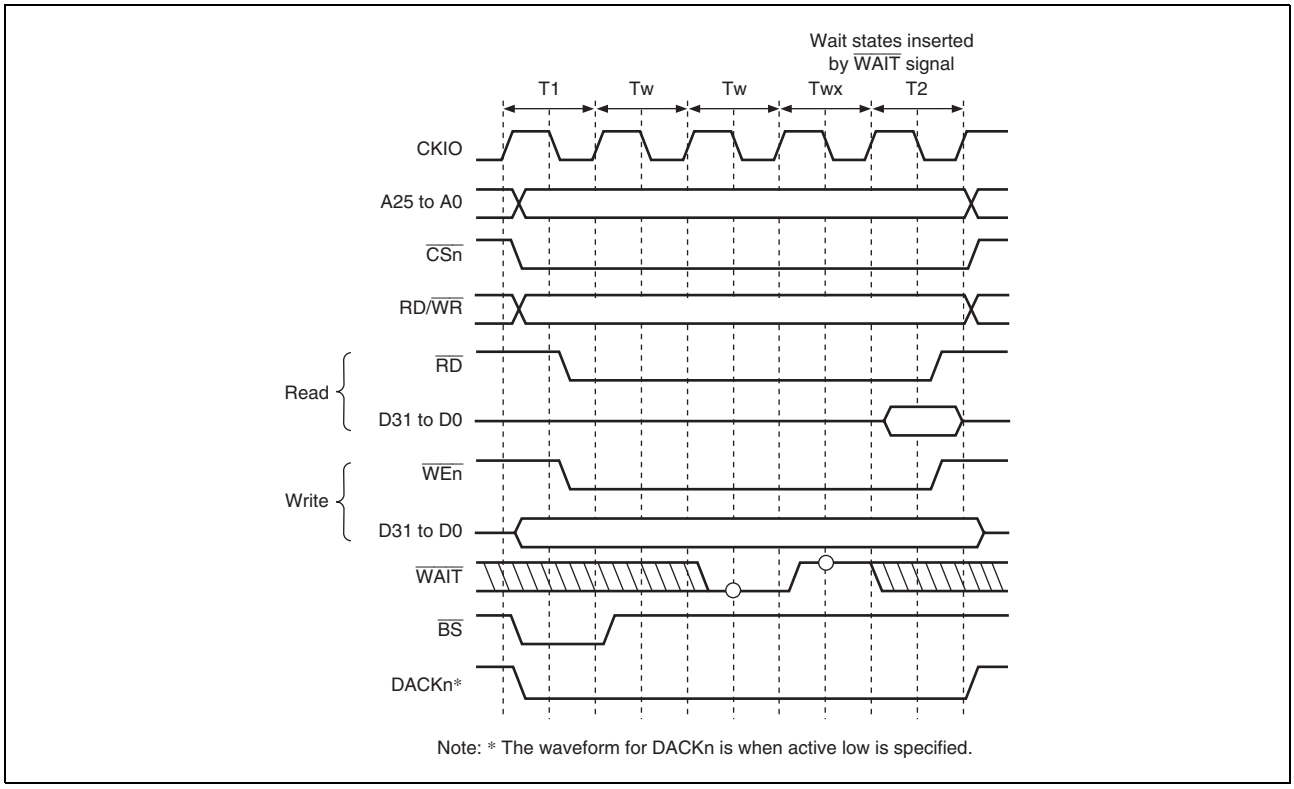

Figure 8.9 Wait Cycle Timing for Normal Space Access (Wait Cycle Insertion Using $\overline{\text{WAIT}}$ Signal)

8.5.4 $\overline{\text{CSn}}$ Assert Period Expansion

The number of cycles from $\overline{\text{CSn}}$ assertion to $\overline{\text{RD}}$, $\overline{\text{WEn}}$ assertion can be specified by setting bits SW1 and SW0 in CSnWCR. The number of cycles from $\overline{\text{RD}}$, $\overline{\text{WEn}}$ negation to $\overline{\text{CSn}}$ negation can be specified by setting bits HW1 and HW0. Therefore, a flexible interface to an external device can be obtained. Figure 8.10 shows an example. A Th cycle and a Tf cycle are added before and after an ordinary cycle, respectively. In these cycles, $\overline{\text{RD}}$ and $\overline{\text{WEn}}$ are not asserted, while other signals are asserted. The data output is prolonged to the Tf cycle, and this prolongation is useful for devices with slow writing operations.

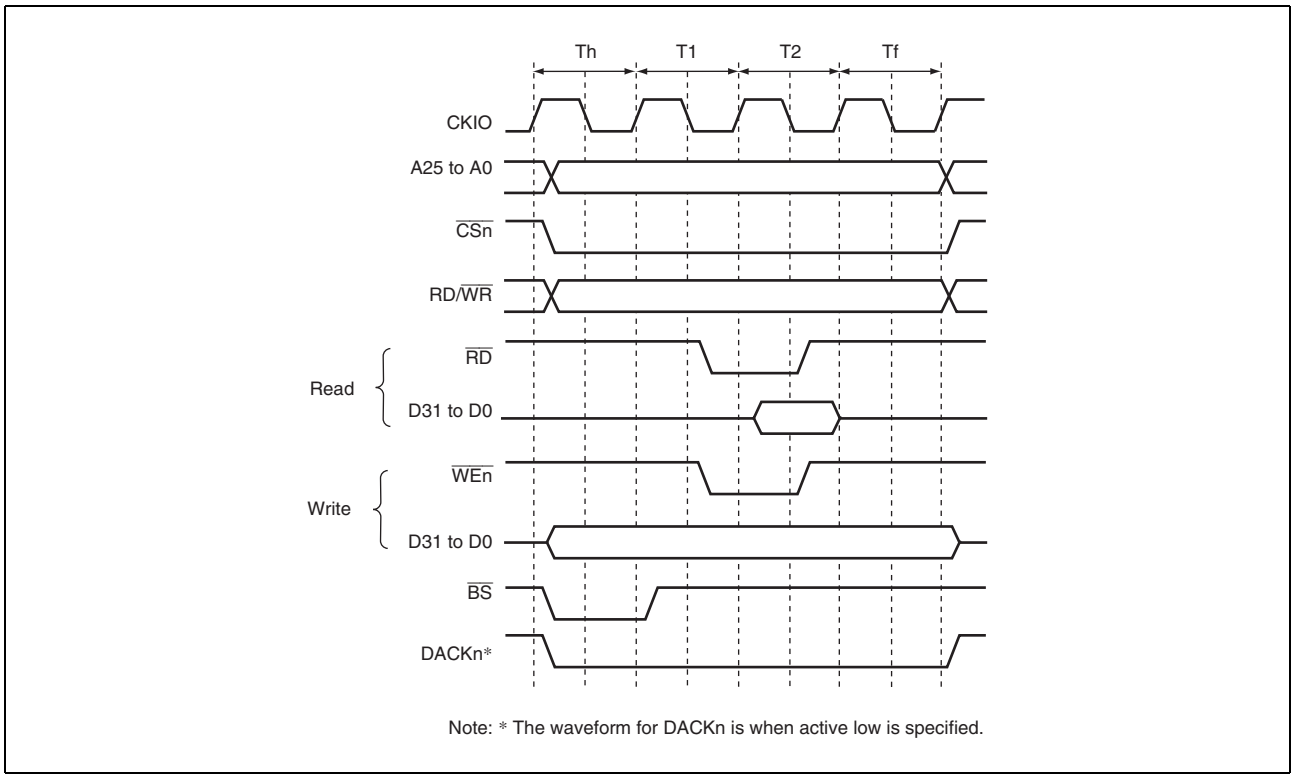

Figure 8.10 $\overline{\text{CSn}}$ Assert Period Expansion

8.5.5 MPX-I/O Interface

Access timing for the MPX space is shown below. In the MPX space, $\overline{CS5}$, $\overline{AH}$, $\overline{RD}$, and $\overline{WEn}$ signals control the accessing. The basic access for the MPX space consists of 2 cycles of address output followed by an access to a normal space. The bus width for the address output cycle or the data input/output cycle is fixed to 8 bits or 16 bits. Alternatively, it can be 8 bits or 16 bits depending on the address to be accessed.

Output of the addresses D15 to D0 or D7 to D0 is performed from cycle Ta2 to cycle Ta3. Because cycle Ta1 has a high-impedance state, collisions of addresses and data can be avoided without inserting idle cycles, even in continuous access cycles. Address output is increased to 3 cycles by setting the MPXW bit in CS5WCR to 1.

The RD/$\overline{WR}$ signal is output at the same time as the $\overline{CS5}$ signal; it is high in the read cycle and low in the write cycle. The data cycle is the same as that in a normal space access.

The delay cycles the number of which is specified by SW[1:0] are inserted between cycle Ta3 and cycle T1. The delay cycles the number of which is specified by HW[1:0] are added after cycle T2.

Timing charts are shown in Figure 8.11 to Figure 8.13.

8.5.6 SDRAM Interface

(1) SDRAM Direct Connection

The SDRAM that can be connected to this LSI is a product that has 11/12/13 bits of row address, 8/9/10 bits of column address, 4 or less banks, and uses the A10 pin for setting precharge mode in read and write command cycles.
The control signals for direct connection of SDRAM are $\overline{RAS}$, $\overline{CAS}$, RD/$\overline{WR}$, DQMUU, DQMUL, DQMLU, DQMLL, CKE, $\overline{CS2}$, and $\overline{CS3}$. All the signals other than $\overline{CS2}$ and $\overline{CS3}$ are common to all areas, and signals other than CKE are valid only when $\overline{CS2}$ or $\overline{CS3}$ is asserted. SDRAM can be connected to up to 2 spaces. The data bus width of the area that is connected to SDRAM is 16 bits or 32 bits.
Burst read/single write (burst length 1) and burst read/burst write (burst length 1) are supported as the SDRAM operating mode.
Commands for SDRAM can be specified by $\overline{RAS}$, $\overline{CAS}$, RD/$\overline{WR}$, and specific address signals. These commands supports:

- NOP
- Auto-refresh (REF)
- Self-refresh (SELF)
- All banks pre-charge (PALL)
- Specified bank pre-charge (PRE)
- Bank active (ACTV)
- Read (READ)
- Read with pre-charge (READA)
- Write (WRIT)
- Write with pre-charge (WRITA)
- Write mode register (MRS, EMRS)

The byte to be accessed is specified by DQMUU, DQMUL, DQMLU, and DQMLL. Reading or writing is performed for a byte whose corresponding DQMxx is low. For details on the relationship between DQMxx and the byte to be accessed, see section 8.5.1, Access Size and Data Alignment.

Figure 8.14 and Figure 8.15 show examples of the connection of the SDRAM with the LSI.

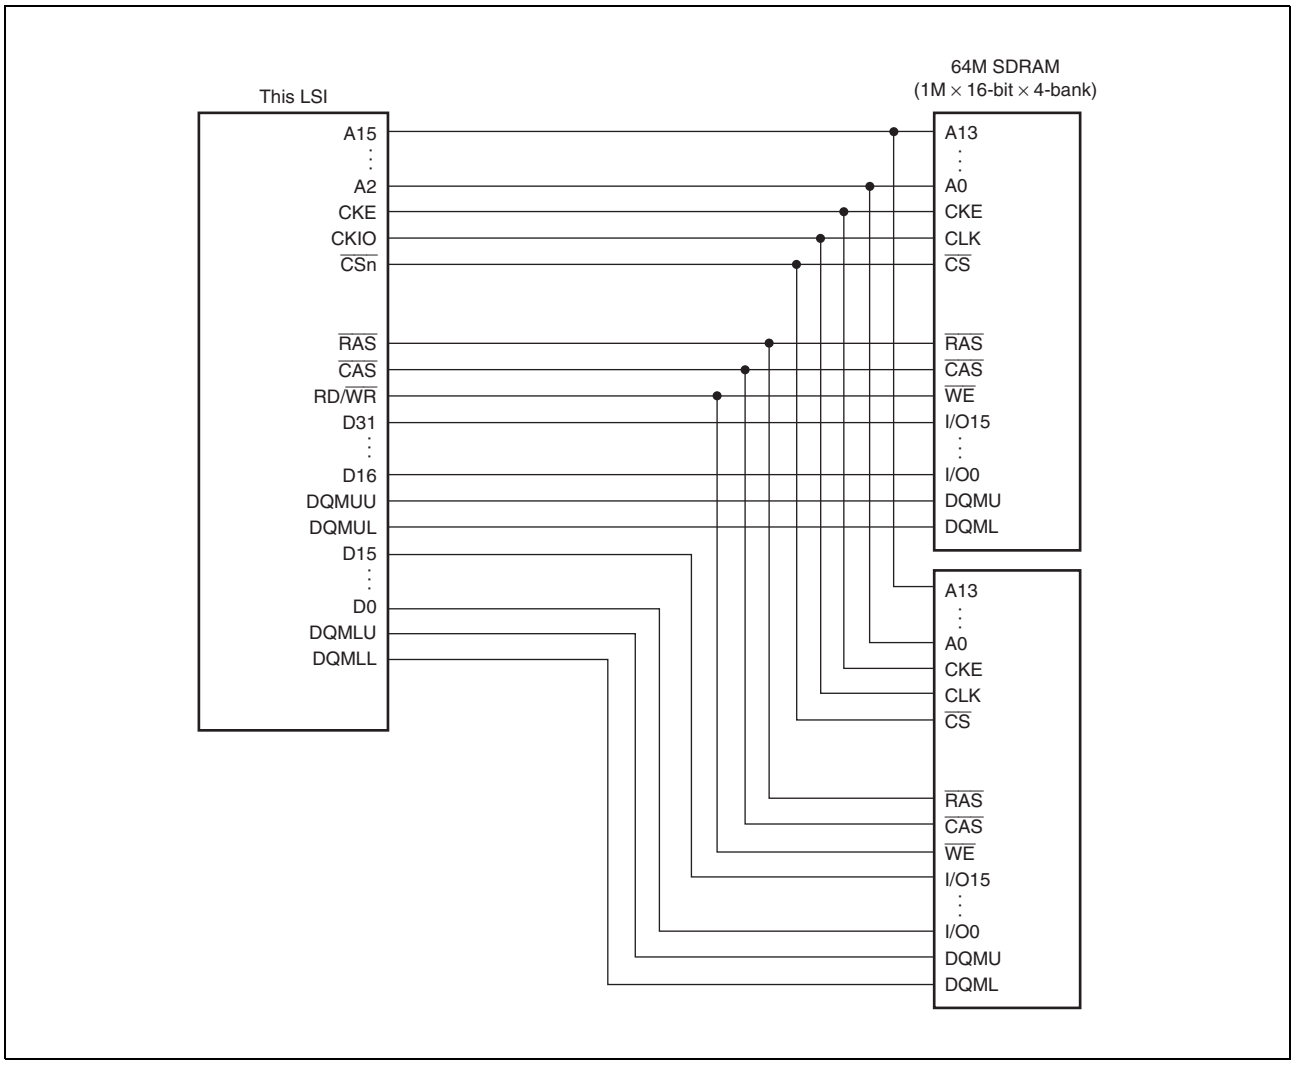

Figure 8.14 Example of 32-Bit Data Width SDRAM Connection

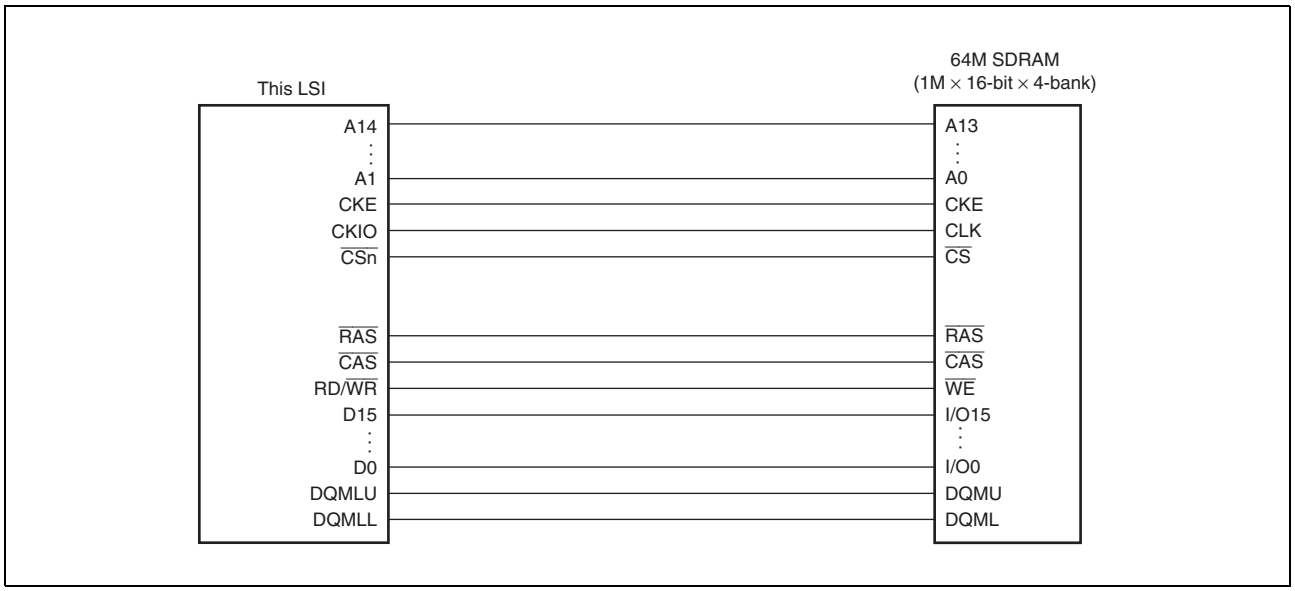

Figure 8.15 Example of 16-Bit Data Width SDRAM Connection

(2) Address Multiplexing

An address multiplexing is specified so that SDRAM can be connected without external multiplexing circuitry according to the setting of bits BSZ[1:0] in CSnBCR and bits A2ROW[1:0], A2COL[1:0], A3ROW[1:0], and A3COL[1:0] in SDCR. Table 8.8 to Table 8.13 show the relationship between the settings of bits BSZ[1:0], A2ROW[1:0], A2COL[1:0], A3ROW[1:0], and A3COL[1:0] and the bits output at the address pins. Do not specify those bits in the manner other than this table, otherwise the operation of this LSI is not guaranteed. A25 to A18 are not multiplexed and the original values of address are always output at these pins.

When the data bus width is 16 bits (BSZ1 and BSZ0 = B'10), A0 of SDRAM specifies a 16-bit address. Therefore, connect this A0 pin of SDRAM to the A1 pin of the LSI; the A1 pin of SDRAM to the A2 pin of the LSI, and so on.

When the data bus width is 32 bits (BSZ1 and BSZ0 = B'11), A0 of SDRAM specifies a 32-bit address. Therefore, connect this A0 pin of SDRAM to the A2 pin of the LSI; the A1 pin of SDRAM to the A3 pin of the LSI, and so on.

(3) Burst Read

A burst read occurs in the following cases with this LSI.

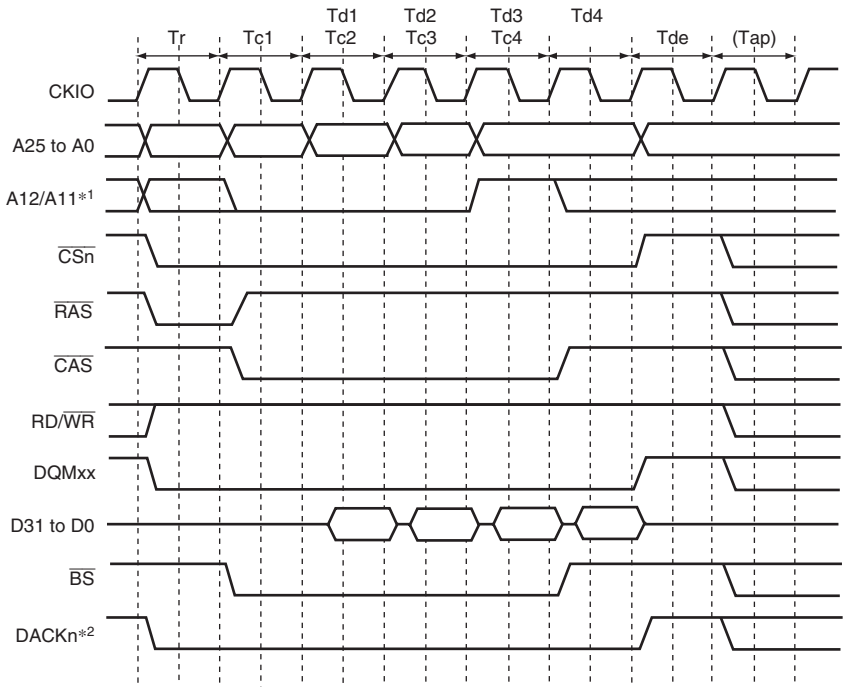
- Access size in reading is larger than data bus width.
- 16-, 32- or 64-byte transfer

This LSI always accesses the SDRAM with burst length 1. For example, read access of burst length 1 is performed consecutively 8 times to read 16-byte continuous data from the SDRAM that is connected to a 16-bit data bus. This access is called the burst read with the burst number 8. Table 8.14 shows the relationship between the access size and the number of bursts.

Table 8.14 Relationship between Access Size and Number of Bursts

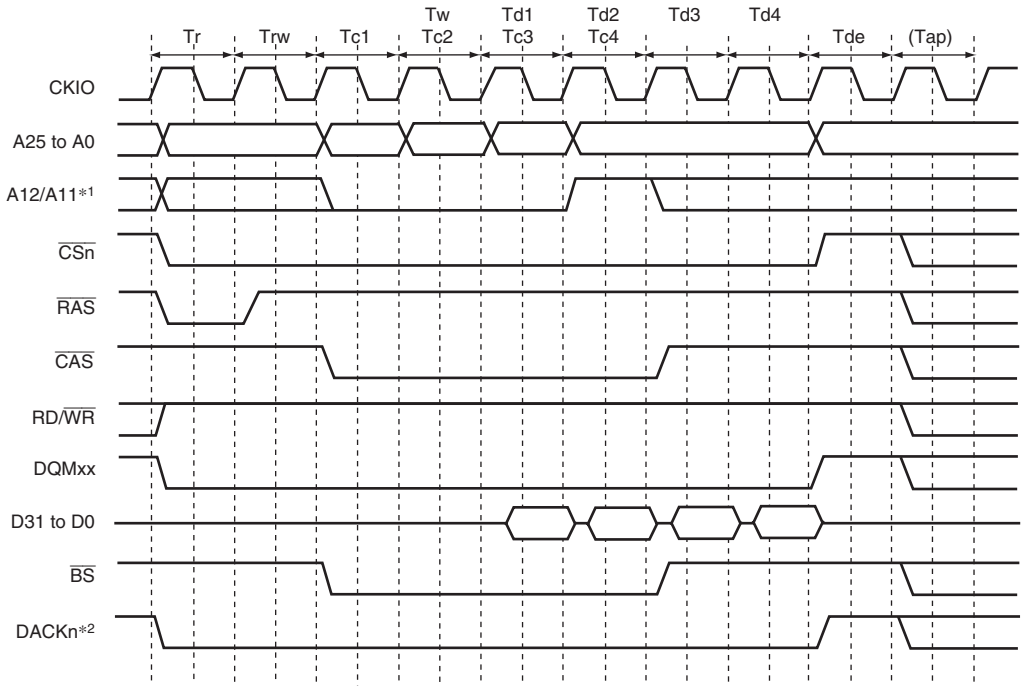
Bus Width	Access Size	Number of Bursts
16 bits	8 bits	1
	16 bits	1
	32 bits	2
	16 bytes	8
	32 bytes	16
	64 bytes	32
32 bits	8 bits	1
	16 bits	1
	32 bits	1
	16 bytes	4
	32 bytes	8
	64 bytes	16

Figure 8.16 and Figure 8.17 show timing charts in burst read. In burst read, an ACTV command is output in the Tr cycle, the READ command is issued in the Tc1, Tc2, and Tc3 cycles, the READA command is issued in the Tc4 cycle, and the read data is received at the rising edge of the external clock (CKIO) in the Td1 to Td4 cycles. The Tap cycle is used to wait for the completion of an auto-precharge induced by the READA command in the SDRAM. In the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.
In this LSI, wait cycles can be inserted by specifying each bit in CS3WCR to connect the SDRAM in variable frequencies. Figure 8.17 shows an example in which wait cycles are inserted. The number of cycles from the Tr cycle where the ACTV command is output to the Tc1 cycle where the READ command is output can be specified using the WTRCD1 and WTRCD0 bits in CS3WCR. If the WTRCD1 and WTRCD0 bits specify one cycle or more, a Trw cycle where the NOP command is issued is inserted between the Tr cycle and Tc1 cycle. The number of cycles from the Tc1 cycle where the READ command is output to the Td1 cycle where the read data is latched can be specified for the CS2 and CS3 spaces independently, using the A2CL1 and A2CL0 bits in CS2WCR or the A3CL1 and A3CL0 bits in CS3WCR. The number of cycles from Tc1 to Td1 corresponds to the SDRAM CAS latency. The CAS latency for the SDRAM is normally defined as up to three cycles. However, the CAS latency in this LSI can be specified as 1 to 4 cycles. This CAS latency can be achieved by connecting a latch circuit between this LSI and the SDRAM.
A Tde cycle is an idle cycle required to transfer the read data into this LSI and occurs once for every burst read or every single read.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.16 Burst Read Basic Timing (CAS Latency 1, Auto Pre-Charge)



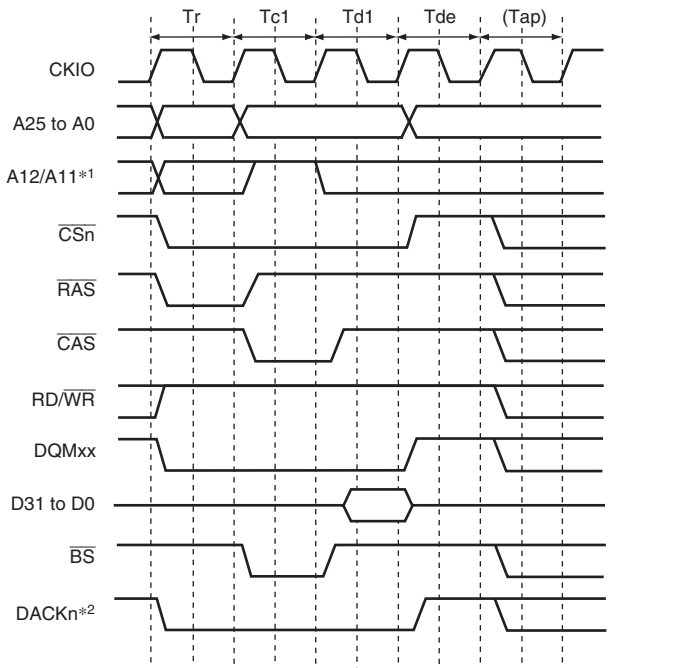
Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.17 Burst Read Wait Specification Timing (CAS Latency 2, WTRCD[1:0] = 1 Cycle, Auto Pre-Charge)

(4) Single Read

A read access ends in one cycle when the data bus width is larger than or equal to the access size. As the SDRAM is set to the burst read with the burst length 1, only the required data is output. A read access that ends in one cycle is called single read.

Figure 8.18 shows the single read basic timing.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

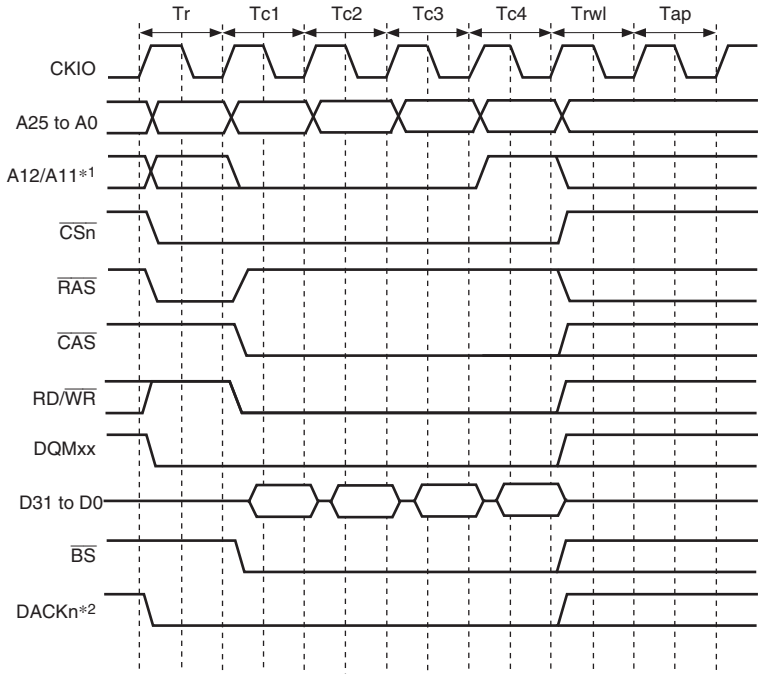
Figure 8.18 Basic Timing for Single Read (CAS Latency 1, Auto Pre-Charge)

(5) Burst Write

A burst write occurs in the following cases in this LSI.

- Access size in writing is larger than data bus width.
- 16-, 32- or 64-byte transfer

This LSI always accesses SDRAM with burst length 1. For example, write access of burst length 1 is performed continuously 8 times to write 16-byte continuous data to the SDRAM that is connected to a 16-bit data bus. This access is called burst write with the burst number 8. The relationship between the access size and the number of bursts is shown in Table 8.14. Figure 8.19 shows a timing chart for burst writes. In burst write, an ACTV command is output in the Tr cycle, the WRIT command is issued in the Tc1, Tc2, and Tc3 cycles, and the WRITA command is issued to execute an auto-precharge in the Tc4 cycle. In the write cycle, the write data is output simultaneously with the write command. After the write command with the auto-precharge is output, the Trw1 cycle that waits for the auto-precharge initiation is followed by the Tap cycle that waits for completion of the auto-precharge induced by the WRITA command in the SDRAM. Between the Trwl and the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Trw1 cycles is specified by the TRWL1 and TRWL0 bits in CS3WCR. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.

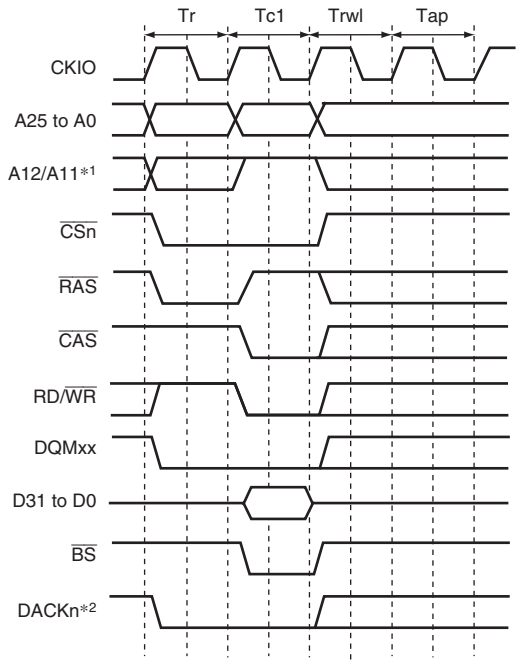


Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.19 Basic Timing for Burst Write (Auto Pre-Charge)

(6) Single Write

A write access ends in one cycle when the data bus width is larger than or equal to access size. As a single write or burst write with burst length 1 is set in SDRAM, only the required data is output. The write access that ends in one cycle is called single write. Figure 8.20 shows the single write basic timing.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.20 Single Write Basic Timing (Auto-Precharge)

(7) Bank Active

The SDRAM bank function can be used to support high-speed access to the same row address. When the BACTV bit in SDCR is 1, access is performed using commands without auto-precharge (READ or WRIT). This function is called bank-active function. This function is valid only for area 3. When area 3 is set to bank-active mode, area 2 should be set to normal space or SRAM with byte selection. When areas 2 and 3 are both set to SDRAM, auto precharge mode must be set.

When the bank-active function is used, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command. As SDRAM is internally divided into several banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued. The number of cycles between issuance of the PRE command and the ACTV command is determined by the WTRP1 and WTPR0 bits in CS3WCR.

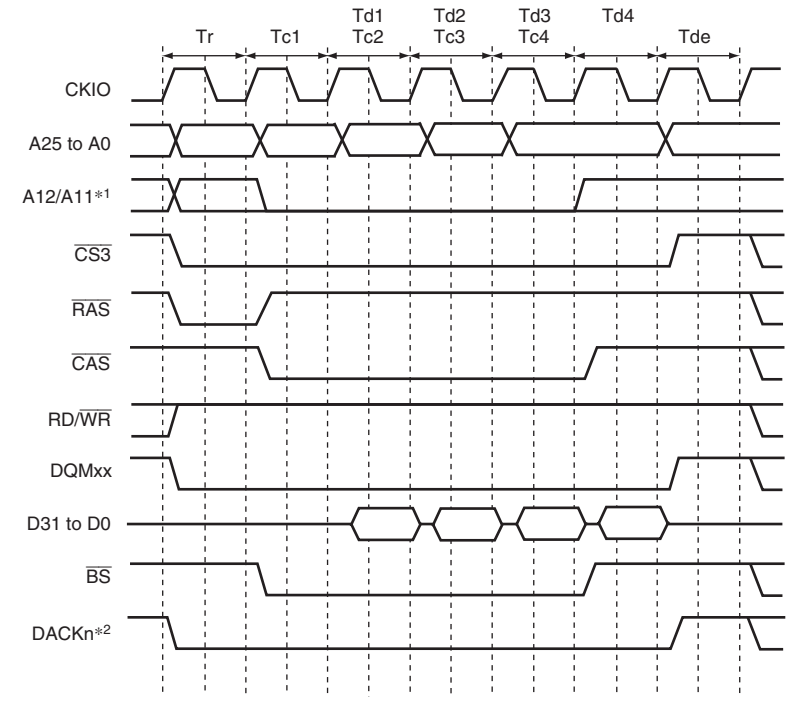
In a write, when an auto-precharge is performed, a command cannot be issued to the same bank for a period of Trwl + Tap cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by Trwl + Tap cycles for each write.

There is a limit on tRAS, the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of tRAS.

A burst read cycle without auto-precharge is shown in Figure 8.21, a burst read cycle for the same row address in Figure 8.22, and a burst read cycle for different row addresses in Figure 8.23. Similarly, a single write cycle without auto-precharge is shown in Figure 8.24, a single write cycle for the same row address in Figure 8.25, and a single write cycle for different row addresses in Figure 8.26.

In Figure 8.22, a Tnop cycle in which no operation is performed is inserted before the Tc cycle that issues the READ command. The Tnop cycle is inserted to acquire two cycles of CAS latency for the DQMxx signal that specifies the read byte in the data read from the SDRAM. If the CAS latency is specified as two cycles or more, the Tnop cycle is not inserted because the two cycles of latency can be acquired even if the DQMxx signal is asserted after the Tc cycle.

When bank active mode is set, if only access cycles to the respective banks in the area 3 space are considered, as long as access cycles to the same row address continue, the operation starts with the cycle in Figure 8.21 or Figure 8.24, followed by repetition of the cycle in Figure 8.22 or Figure 8.25. An access to a different area during this time has no effect. If there is an access to a different row address in the bank active state, the bus cycle in Figure 8.23 or Figure 8.26 is executed instead of that in Figure 8.22 or Figure 8.25. In bank active mode, too, all banks become inactive after a refresh cycle.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.

Figure 8.26 Single Write Timing (Bank Active, Different Row Addresses in the Same Bank)

(8) Refreshing

This module has a function for controlling SDRAM refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in SDCR. A continuous refreshing can be performed by setting the RRC2 to RRC0 bits in RTCSR. If SDRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

(a) Auto-refreshing

Refreshing is performed at intervals determined by the input clock selected by bits CKS2 to CKS0 in RTCSR, and the value set by in RTCOR. The value of bits CKS2 to CKS0 in RTCOR should be set so as to satisfy the refresh interval stipulation for the SDRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in SDCR, and then make the CKS2 to CKS0 and RRC2 to RRC0 settings. When the clock is selected by bits CKS2 to CKS0, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed for the number of times specified by the RRC2 to RRC0. At the same time, RTCNT is cleared to zero and the count-up is restarted.
Figure 8.27 shows the auto-refresh cycle timing. After starting the auto refreshing, PALL command is issued in the Tp cycle to make all the banks to pre-charged state from active state when some bank is being pre-charged. Then REF command is issued in the Trr cycle after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR. A new command is not issued for the duration of the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR after the Trr cycle. The WTRC1 and WTRC0 bits must be set so as to satisfy the SDRAM refreshing cycle time stipulation (tRC). An idle cycle is inserted between the Tp cycle and Trr cycle when the setting value of the WTRP1 and WTRP0 bits in CS3WCR is longer than or equal to 1 cycle.

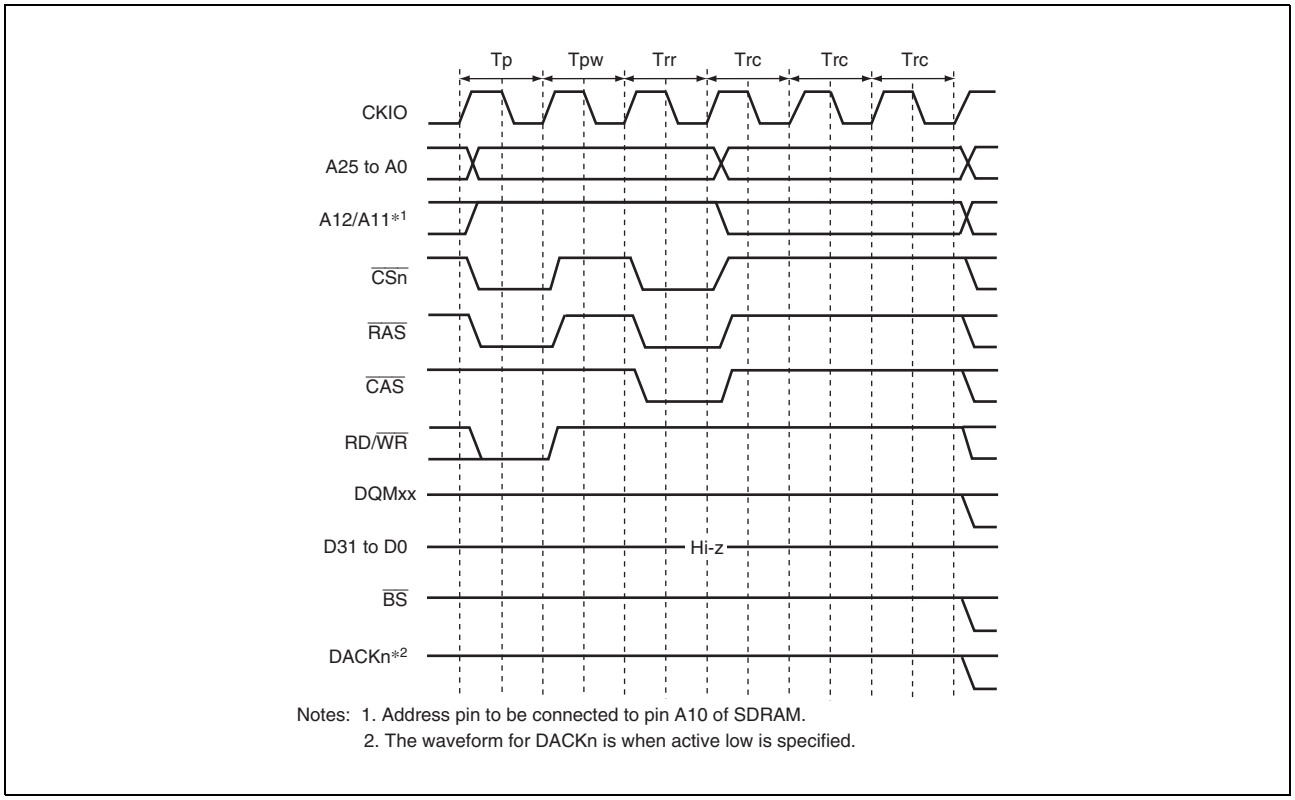

Figure 8.27 Auto-Refresh Timing

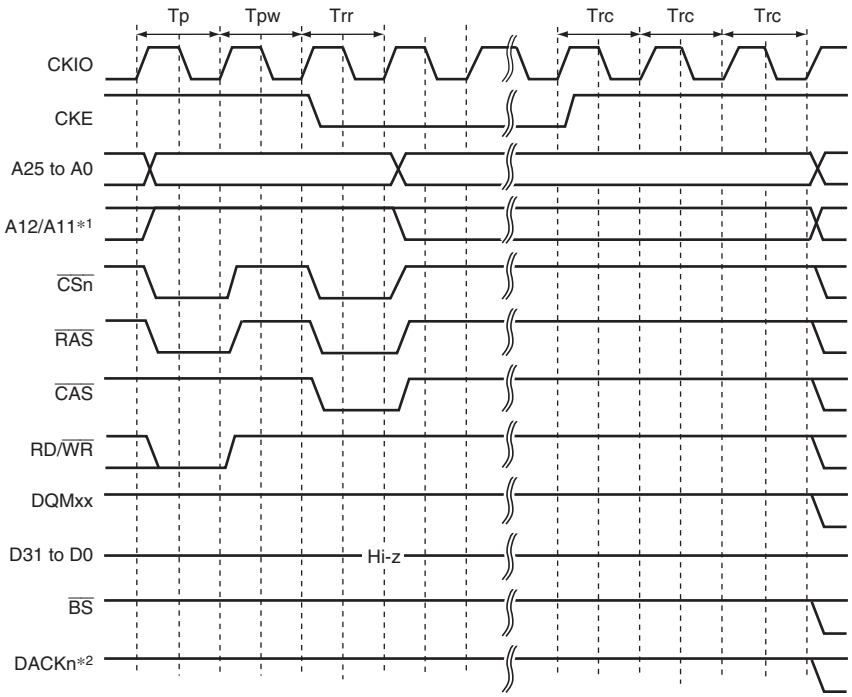
(b) Self-refreshing

Self-refresh mode is a kind of standby mode, in which the refresh timing and refresh addresses are generated within the SDRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit in SDCR to 1. After starting the self-refreshing, PALL command is issued in Tp cycle after the completion of the pre-charging bank. A SELF command is then issued after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WSR. SDRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR.

Self-refresh timing is shown in Figure 8.28. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, auto-refreshing is restarted if the RFSH bit is set to 1 and the RMODE bit is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately.

After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the LSI standby function, and is maintained even after recovery from standby mode due to an interrupt. Note that the necessary signals such as CKE must be driven even in standby state by setting the HIZCNT bit in CMNCR to 1.

In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.28 Self-Refresh Timing

(9) Relationship between Refresh Requests and Bus Cycles

If a refresh request occurs during bus cycle execution, the refresh cycle must wait for the bus cycle to be completed.
If a new refresh request occurs while waiting for the previous refresh request, the previous refresh request is deleted. To refresh correctly, a bus cycle longer than the refresh interval must be prevented from occurring.

(10) Power-Down Mode

If the PDOWN bit in SDCR is set to 1, the SDRAM is placed in power-down mode by bringing the CKE signal to the low level in the non-access cycle. This power-down mode can effectively lower the power consumption in the non-access cycle. However, note that if an access occurs in power-down mode, a cycle of overhead occurs because a cycle is needed to assert the CKE in order to cancel the power-down mode.
Figure 8.29 shows the access timing in power-down mode.

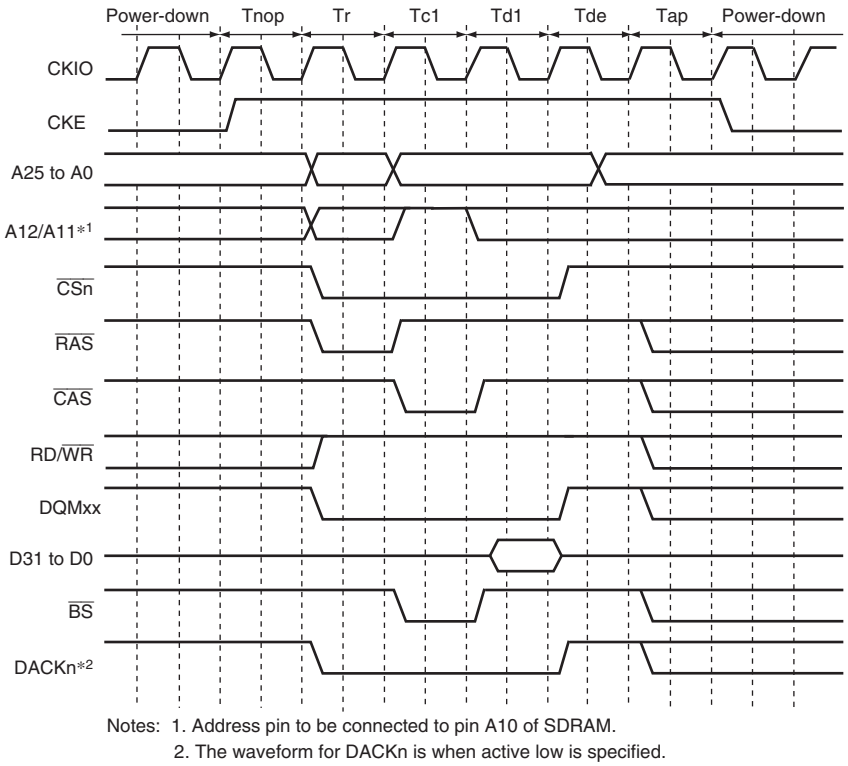


Figure 8.29 Power-Down Mode Access Timing

(11) Power-On Sequence

In order to use SDRAM, mode setting must first be made for SDRAM after the pose interval specified for the SDRAM to be used after powering on. The pose interval should be obtained by a power-on reset generating circuit or software.
To perform SDRAM initialization correctly, the registers of this module must first be set, followed by a write to the SDRAM mode register. In SDRAM mode register setting, the address signal value at that time is latched by a combination of the $\overline{CSn}$, $\overline{RAS}$, $\overline{CAS}$, and RD/$\overline{WR}$ signals. If the value to be set is X, the bus state controller provides for value X to be written to the SDRAM mode register by performing a 16-bit write to address H'3FFFD000 + X for area 2 SDRAM, and to address H'3FFFE000 + X for area 3 SDRAM. In this operation the data is ignored, but the mode write is performed as a byte-size access. To set burst read/single write or burst read/burst write (CAS latency 2 to 3, wrap type = sequential, and burst length 1) supported by the LSI, arbitrary data is written in 16 bits to the access addresses shown in Table 8.15. In this time 0 is output at the external address pins of A12 or later.

Table 8.15 Access Address in SDRAM Mode Register Write

- Setting for Area 2
  Burst read/single write (burst length 1):

Data Bus Width	CAS Latency	Access Address	External Address Pin
16 bits	2	H'3FFFD440	H'0000440

Data Bus Width	CAS Latency	Access Address	External Address Pin
16 bits	2	H'3FFFE040	H'0000040
	3	H'3FFFE060	H'0000060
32 bits	2	H'3FFFE080	H'0000080
	3	H'3FFFE0C0	H'00000C0

Mode register setting timing is shown in Figure 8.30. A PALL command (all bank pre-charge command) is firstly issued. A REF command (auto refresh command) is then issued 8 times. An MRS command (mode register write command) is finally issued. Idle cycles, of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR, are inserted between the PALL and the first REF. Idle cycles, of which number is specified by the WTRC1 and WTRC0 bits in CS3WCR, are inserted between REF and REF, and between the 8th REF and MRS. One or more idle cycles are inserted between the MRS and a command to be issued next.
It is necessary to keep idle time of certain cycles for SDRAM before issuing PALL command after power-on. Refer to the manual of the SDRAM for the idle time to be needed. When the pulse width of the reset signal is longer than the idle time, mode register setting can be started immediately after the reset, but care should be taken when the pulse width of the reset signal is shorter than the idle time.

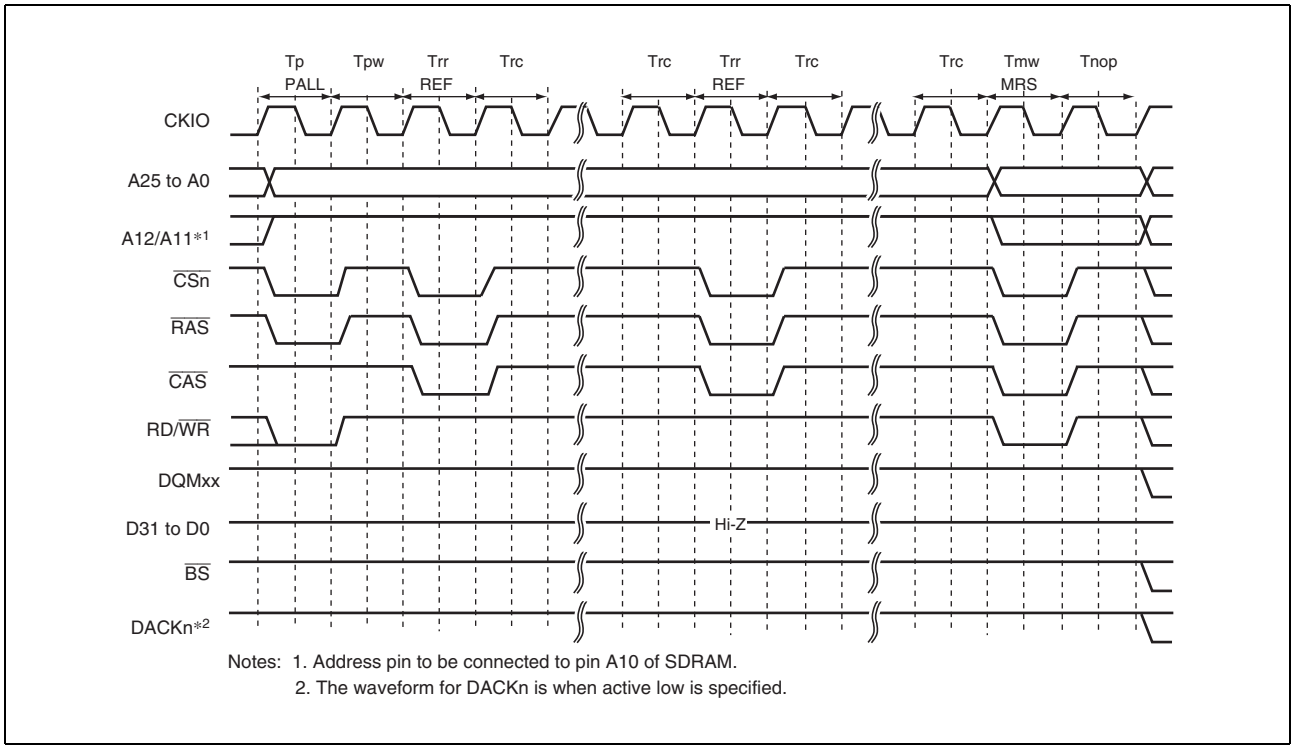

Figure 8.30 SDRAM Mode Write Timing (Based on JEDEC)

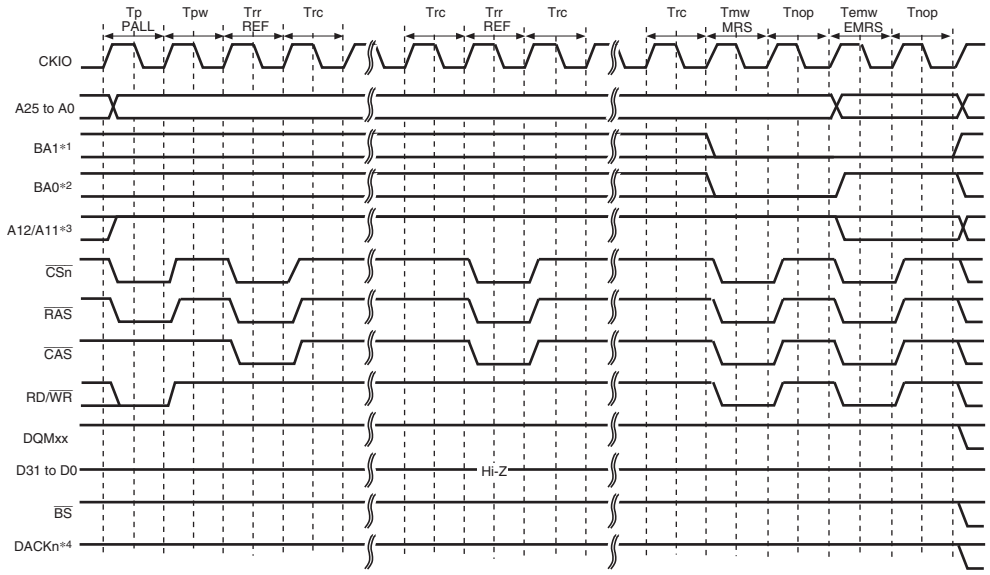
(12) Low-Power SDRAM

The low-power SDRAM can be accessed using the same protocol as the normal SDRAM.
The differences between the low-power SDRAM and normal SDRAM are that partial refresh takes place that puts only a part of the SDRAM in the self-refresh state during the self-refresh function, and that power consumption is low during refresh under user conditions such as the operating temperature. The partial refresh is effective in systems in which the data in a work area other than the specific area can be lost without severe repercussions. For details, refer to the Data Sheet for the low-power SDRAM to be used.
The low-power SDRAM supports the extension mode register in addition to the mode registers as the normal SDRAM. This LSI supports issuing of the extension mode register write command (EMRS).
The EMRS command is issued according to the conditions specified in table below. For example, if data H'0YYYYYYY is written to address H'3FFFEXX0 in 32 bits, the commands are issued to the CS3 space in the following sequence: PALL -> REF × 8 -> MRS -> EMRS. In this case, the MRS and EMRS issue addresses are H'0000XX0 and H'YYYYYYY, respectively. If data H'1YYYYYYY is written to address H'3FFFEXX0 in 32 bits, the commands are issued to the CS3 space in the following sequence: PALL -> MRS -> EMRS.

Table 8.16 Output Addresses when EMRS Command Is Issued

Command to be Issued	Access Address	Access Data	Write Access Size	MRS Command Issue Address	EMRS Command Issue Address
CS2 MRS	H'3FFFDXX0	H'********	16 bits	H'0000XX0	—
CS3 MRS	H'3FFFEXX0	H'********	16 bits	H'0000XX0	—
CS2 MRS + EMRS (with refresh)	H'3FFFDXX0	H'0YYYYYYY	32 bits	H'0000XX0	H'YYYYYYY
CS3 MRS + EMRS (with refresh)	H'3FFFEXX0	H'0YYYYYYY	32 bits	H'0000XX0	H'YYYYYYY
CS2 MRS + EMRS (without refresh)	H'3FFFDXX0	H'1YYYYYYY	32 bits	H'0000XX0	H'YYYYYYY
CS3 MRS + EMRS (without refresh)	H'3FFFEXX0	H'1YYYYYYY	32 bits	H'0000XX0	H'YYYYYYY

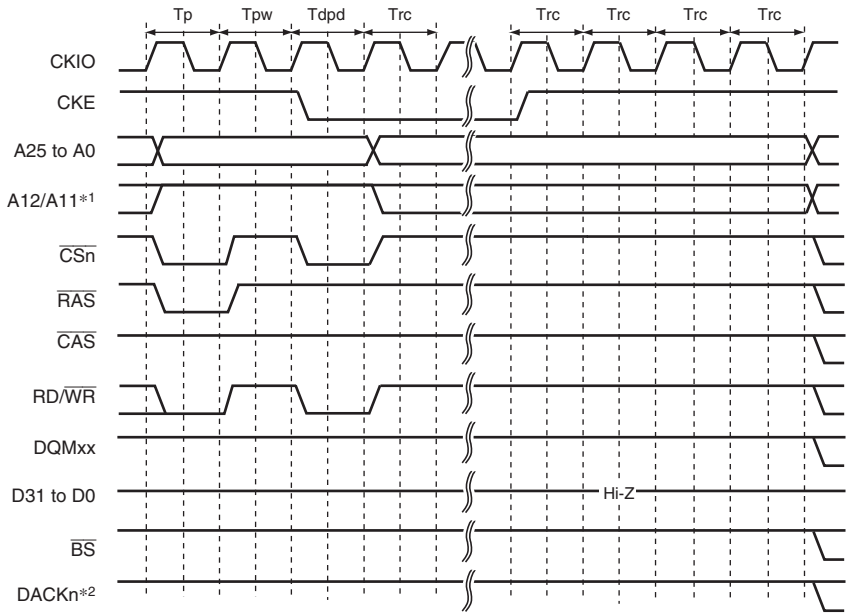


Notes: 1. Address pin to be connected to pin BA1 of SDRAM.
2. Address pin to be connected to pin BA0 of SDRAM.
3. Address pin to be connected to pin A10 of SDRAM.
4. The waveform for DACKn is when active low is specified.

Figure 8.31 EMRS Command Issue Timing

- Deep power-down mode
  The low-power SDRAM supports the deep power-down mode as a low-power consumption mode. In the partial self-refresh function, self-refresh is performed on a specific area. In the deep power-down mode, self-refresh will not be performed on any memory area. This mode is effective in systems where all of the system memory areas are used as work areas.

If the RMODE bit in the SDCR is set to 1 while the DEEP and RFSH bits in the SDCR are set to 1, the low-power SDRAM enters the deep power-down mode. If the RMODE bit is cleared to 0, the CKE signal is pulled high to cancel the deep power-down mode. Before executing an access after returning from the deep power-down mode, the power-up sequence must be re-executed.



Notes: 1. Address pin to be connected to pin A10 of SDRAM.
2. The waveform for DACKn is when active low is specified.

Figure 8.32 Deep Power-Down Mode Transition Timing

8.5.7 Burst ROM (Clocked Asynchronous) Interface

The burst ROM (clocked asynchronous) interface is used to access a memory with a high-speed read function using a method of address switching called the burst mode or page mode. In a burst ROM (clocked asynchronous) interface, basically the same access as the normal space is performed, but the 2nd and subsequent access cycles are performed only by changing the address, without negating the $\overline{RD}$ signal at the end of the 1st cycle. In the 2nd and subsequent access cycles, addresses are changed at the falling edge of the CKIO.

For the 1st access cycle, the number of wait cycles specified by the W3 to W0 bits in CSnWCR is inserted. For the 2nd and subsequent access cycles, the number of wait cycles specified by the BW1 and BW0 bits in CSnWCR is inserted.

In the access to the burst ROM (clocked asynchronous), the $\overline{BS}$ signal is asserted only to the first access cycle. An external wait input is valid only to the first access cycle.

In the single access or write access that does not perform the burst operation in the burst ROM (clocked asynchronous) interface, access timing is same as a normal space.

Table 8.17 lists a relationship between bus width, access size, and the number of bursts. Figure 8.33 shows a timing chart.

Table 8.17 Relationship between Bus Width, Access Size, and Number of Bursts

Bus Width	Access Size	CSnWCR. BST[1:0] Bits	Number of Bursts	Access Count
8 bits	8 bits	Not affected	1	1
	16 bits	Not affected	2	1
	32 bits	Not affected	4	1
	16 bytes	00	16	1
		01	4	4
	32 bytes	00	16	2
		01	4	8
	64 bytes	00	16	4
		01	4	16
16 bits	8 bits	Not affected	1	1
	16 bits	Not affected	1	1
	32 bits	Not affected	2	1
	16 bytes	00	8	1
		01	2	4
		10*1	4	2
			2, 4, 2	3
	32 bytes	00	8	2
		01	2	8
		10*1	4	4
			2, 4, 2	6
	64 bytes	00	8	4
		01	2	16
		10*1	4	8
			2, 4, 2	12
32 bits	8 bits	Not affected	1	1
	16 bits	Not affected	1	1
	32 bits	Not affected	1	1
	16 bytes	Not affected	4	1
	32 bytes	Not affected	4	2
	64 bytes	Not affected	4	4

Note 1. When the bus width is 16 bits, the access size is 16 bytes or more, and the BST[1:0] bits in CSnWCR are 10, the number of bursts and access count depend on the access start address. At address H'xxx0 or H'xxx8, 4-4 burst access is performed. At address H'xxx4 or H'xxxC, 2-4-2 burst access is performed.

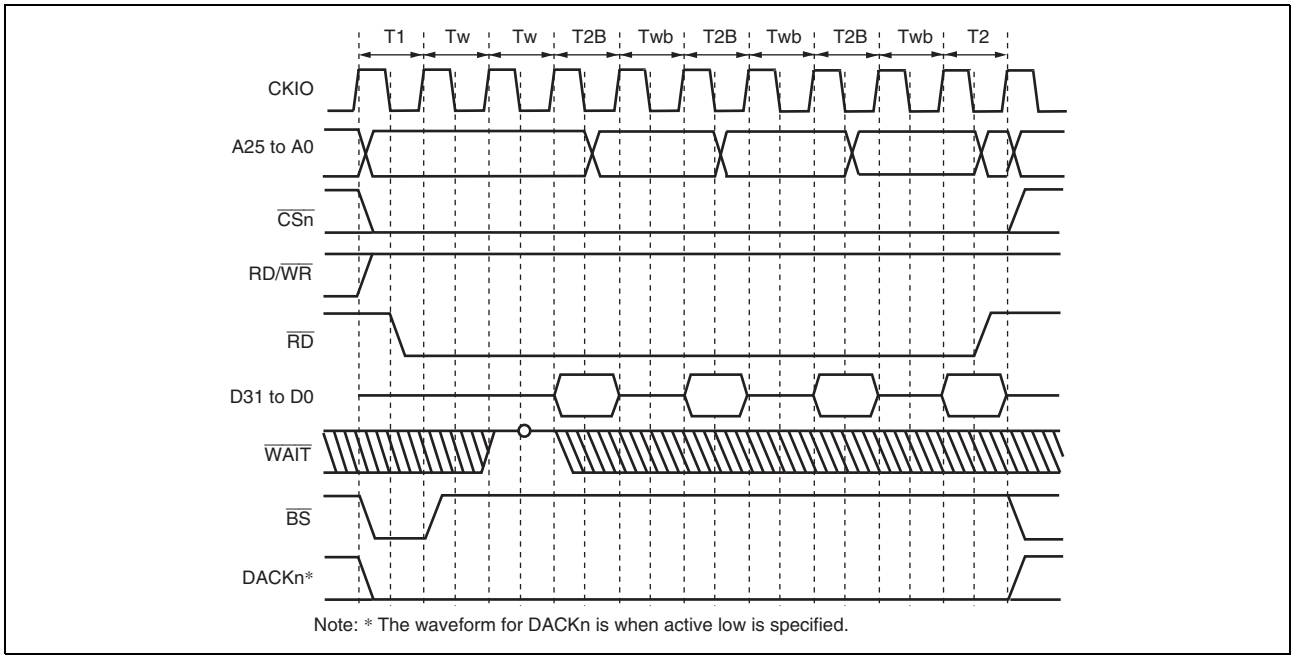


Figure 8.33 Burst ROM Access Timing (Clocked Asynchronous) (Bus Width = 32 Bits, 16-Byte Transfer (Number of Burst 4), Wait Cycles Inserted in First Access = 2, Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)

8.5.8 SRAM Interface with Byte Selection

The SRAM interface with byte selection is a memory interface that outputs the byte selection signal ($\overline{\text{WEn}}$) in both read and write bus cycles. This interface has 16-bit data pins and accesses SRAMs having upper and lower byte selection pins, such as $\overline{\text{UB}}$ and $\overline{\text{LB}}$.

When the BAS bit in CSnWCR is cleared to 0 (initial value), the write access timing of the SRAM interface with byte selection is the same as that for the normal space interface. While in read access of a byte-selection SRAM interface, the byte-selection signal is output from the $\overline{\text{WEn}}$ pin, which is different from that for the normal space interface. The basic access timing is shown in Figure 8.34. In write access, data is written to the memory according to the timing of the byte-selection pin ($\overline{\text{WEn}}$). For details, refer to the Data Sheet for the corresponding memory.

If the BAS bit in CSnWCR is set to 1, the $\overline{\text{WEn}}$ pin and RD/$\overline{\text{WR}}$ pin timings change. Figure 8.35 shows the basic access timing. In write access, data is written to the memory according to the timing of the write enable pin (RD/$\overline{\text{WR}}$). The data hold timing from RD/$\overline{\text{WR}}$ negation to data write must be acquired by setting the HW1 and HW0 bits in CSnWCR. Figure 8.36 shows the access timing when a software wait is specified.

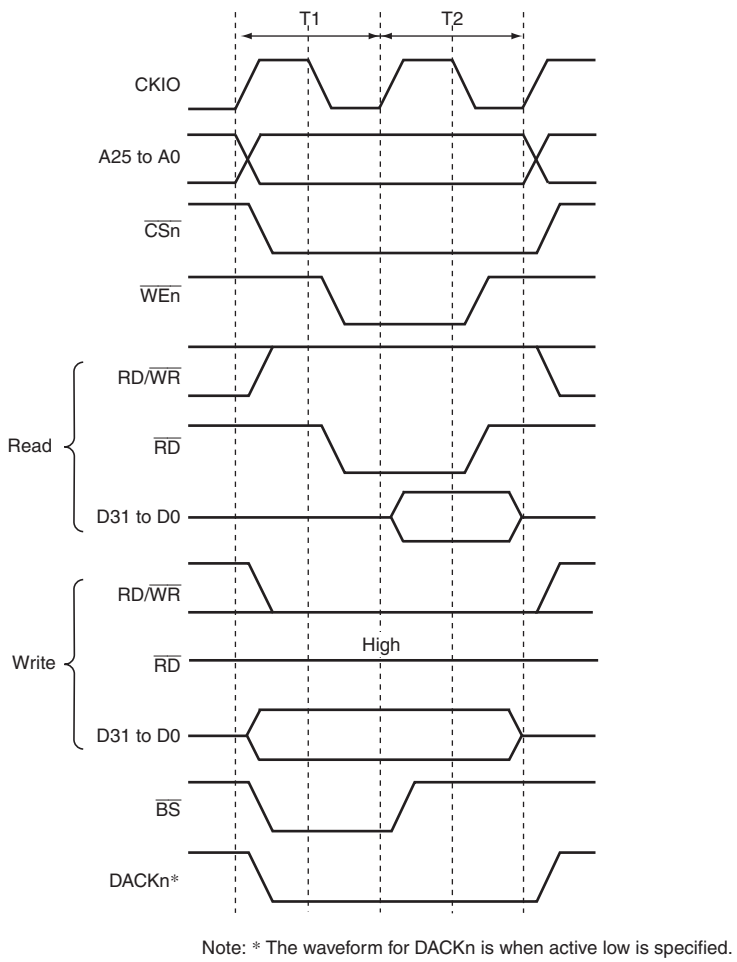

Figure 8.34 Basic Access Timing for SRAM with Byte Selection (BAS = 0)

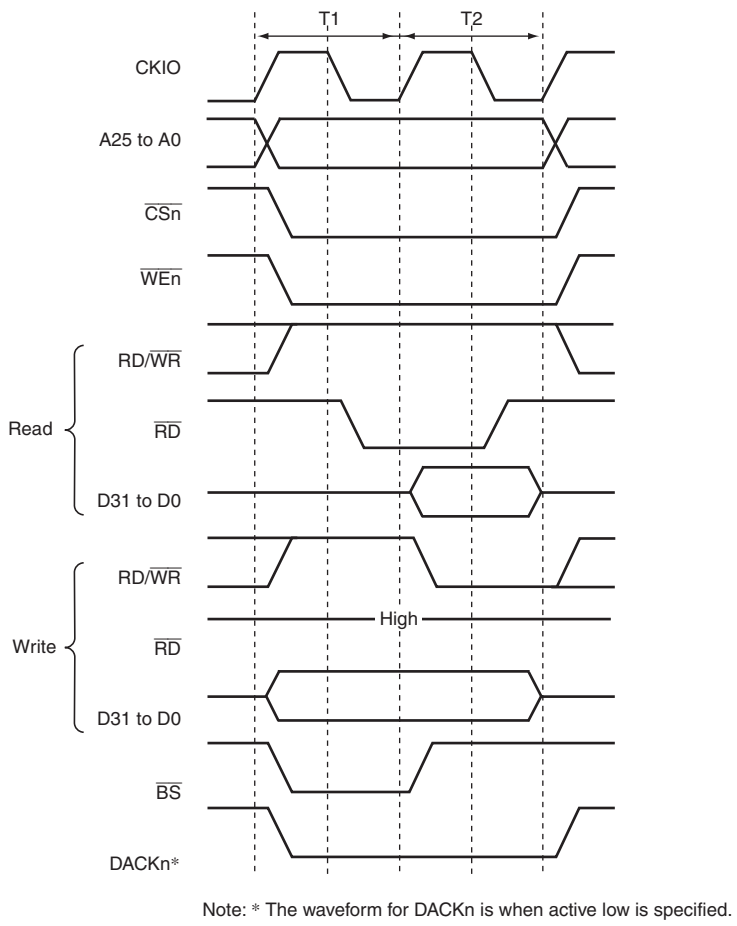

Figure 8.35 Basic Access Timing for SRAM with Byte Selection (BAS = 1)

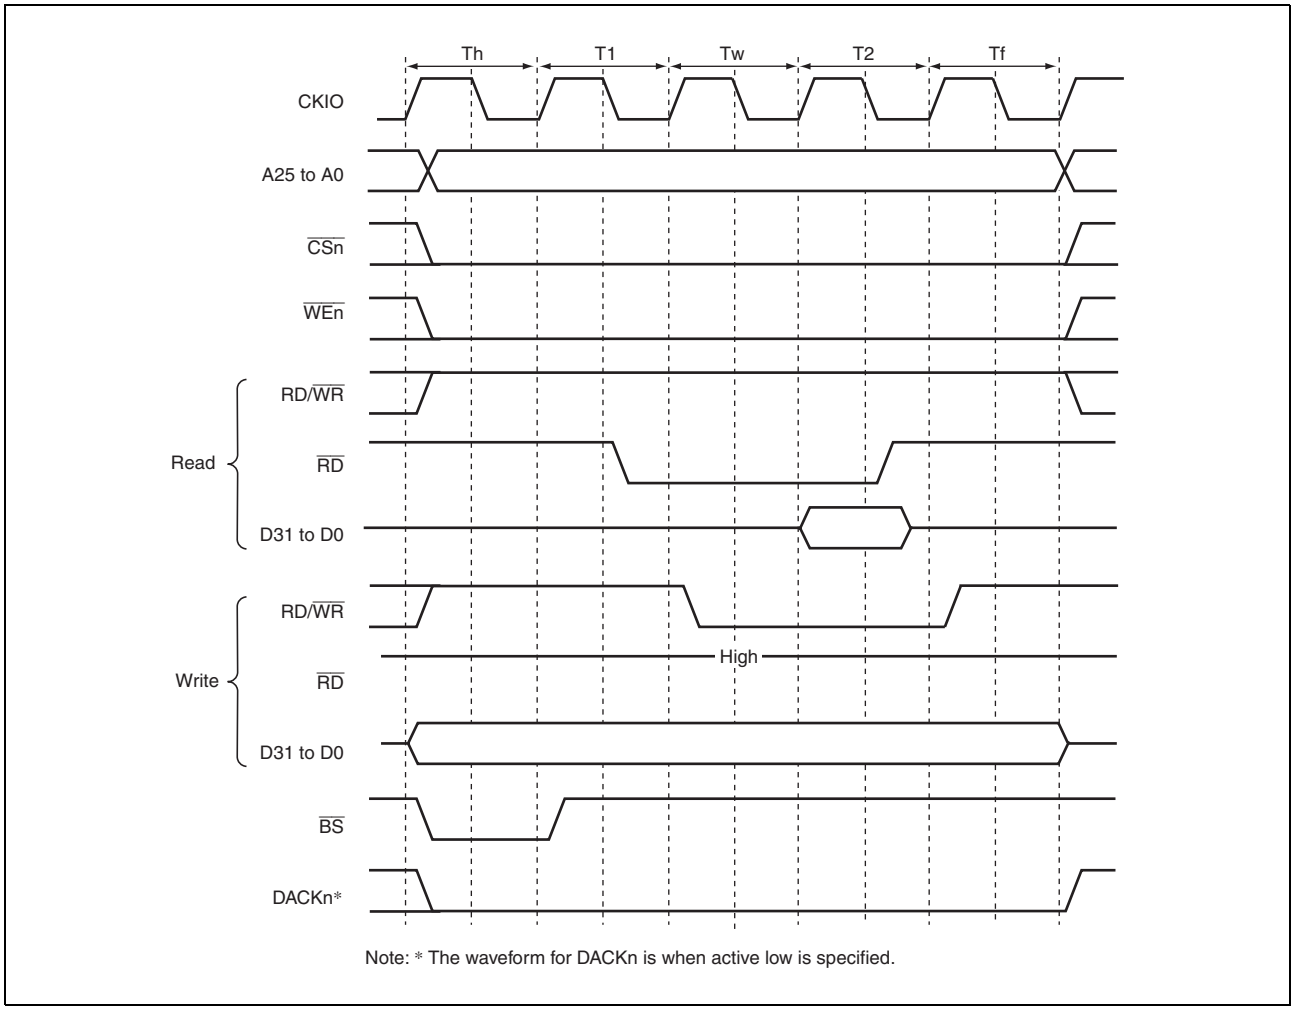

Figure 8.36 Wait Timing for SRAM with Byte Selection (BAS = 1) (SW[1:0] = 01, WR[3:0] = 0001, HW[1:0] = 01)

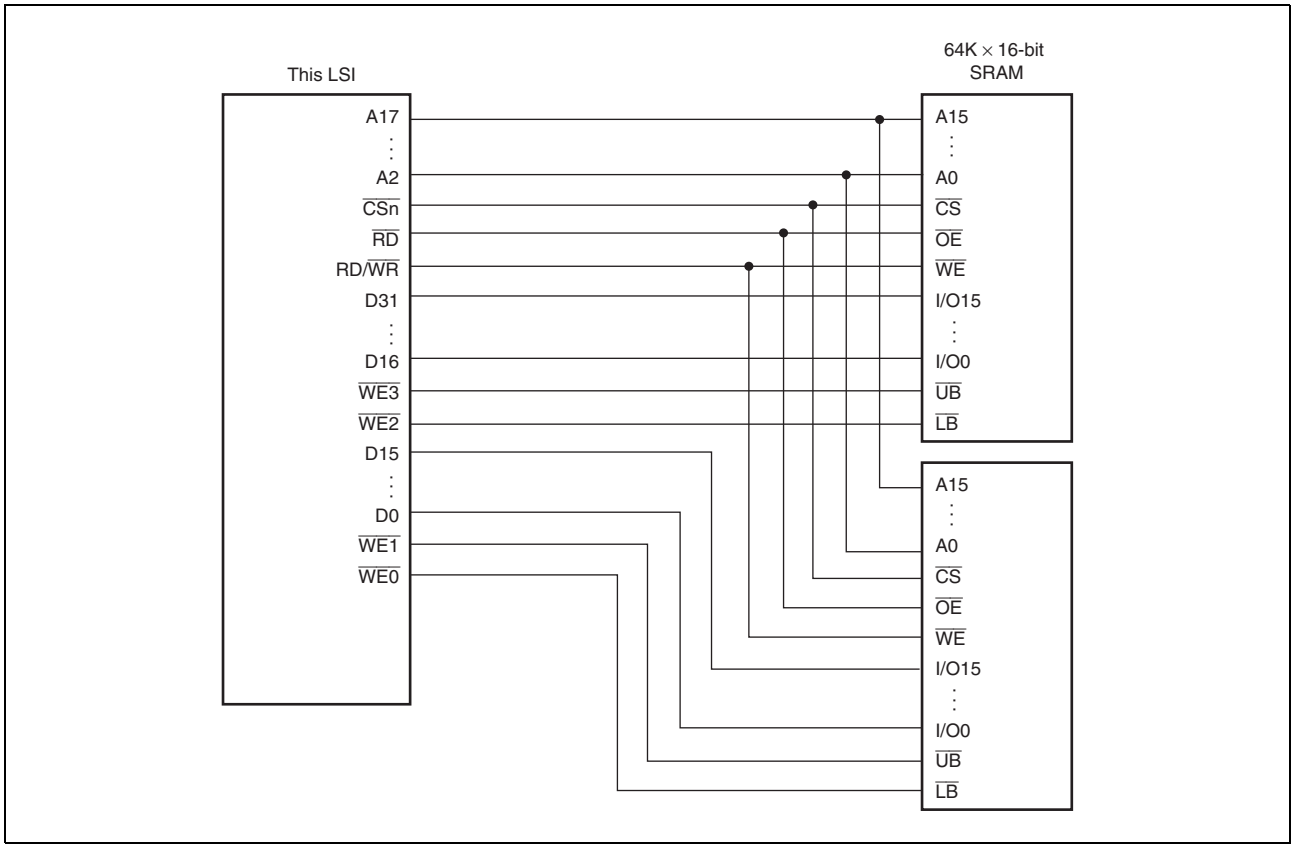

Figure 8.37 Example of Connection with 32-Bit Data-Width SRAM with Byte Selection

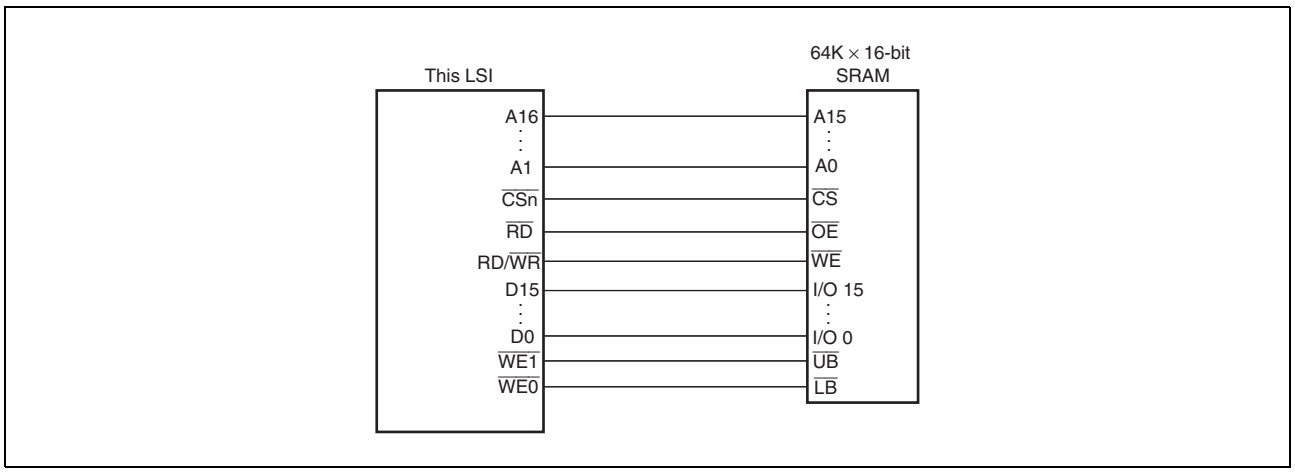

Figure 8.38 Example of Connection with 16-Bit Data-Width SRAM with Byte Selection

8.5.9 Burst ROM (Clocked Synchronous) Interface

The burst ROM (clocked synchronous) interface is supported to access a ROM with a synchronous burst function at high speed. The burst ROM interface accesses the burst ROM in the same way as a normal space. This interface is valid only for area 0.

In the first access cycle, wait cycles are inserted. In this case, the number of wait cycles to be inserted is specified by the W3 to W0 bits in CS0WCR. In the second and subsequent cycles, the number of wait cycles to be inserted is specified by the BW1 and BW0 bits in CS0WCR.

While the burst ROM (clocked synchronous) is accessed, the $\overline{BS}$ signal is asserted only for the first access cycle and an external wait input is also valid for the first access cycle.

When the bus width is 16 bits, the burst length must be specified as 8. When the bus width is 32 bits, the burst length must be specified as 4. The burst ROM interface does not support the 8-bit bus width for the burst ROM.

The burst ROM interface performs burst operations for all read access. For example, in a 32-bit access over a 16-bit bus, valid 16-bit data is read two times and invalid 16-bit data is read six times. These invalid data read cycles increase the memory access time and degrade the program execution speed and DMA transfer speed. To prevent this problem, it is recommended using a read in a 16-byte or more access size. The burst ROM interface performs write access in the same way as normal space access.

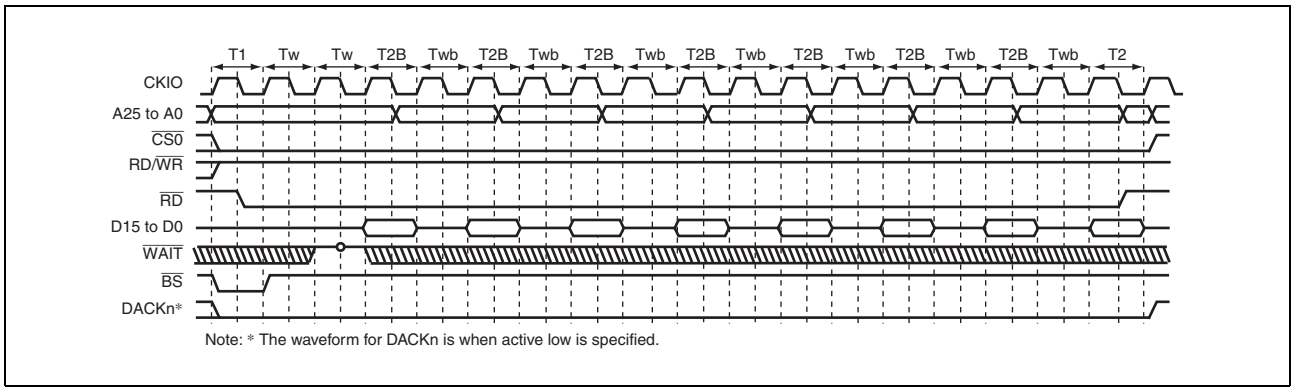

Figure 8.39 Burst ROM Access Timing (Clocked Synchronous) (Burst Length = 8, Wait Cycles Inserted in First Access = 2, Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)

8.5.10 Wait between Access Cycles

As the operating frequency of LSIs becomes higher, the off-operation of the data buffer often collides with the next data access when the read operation from devices with slow access speed is completed. As a result of these collisions, the reliability of the device is low and malfunctions may occur. A function that avoids data collisions by inserting idle (wait) cycles between continuous access cycles has been newly added.
The number of wait cycles between access cycles can be set by the WM bit in CSnWCR, bits IWW2 to IWW0, IWRWD2 to IWRWD0, IWRWS2 to IWRWS0, IWRRD2 to IWRRD0, and IWRRS2 to IWRRS 0 in CSnBCR. The conditions for setting the idle cycles between access cycles are shown below.

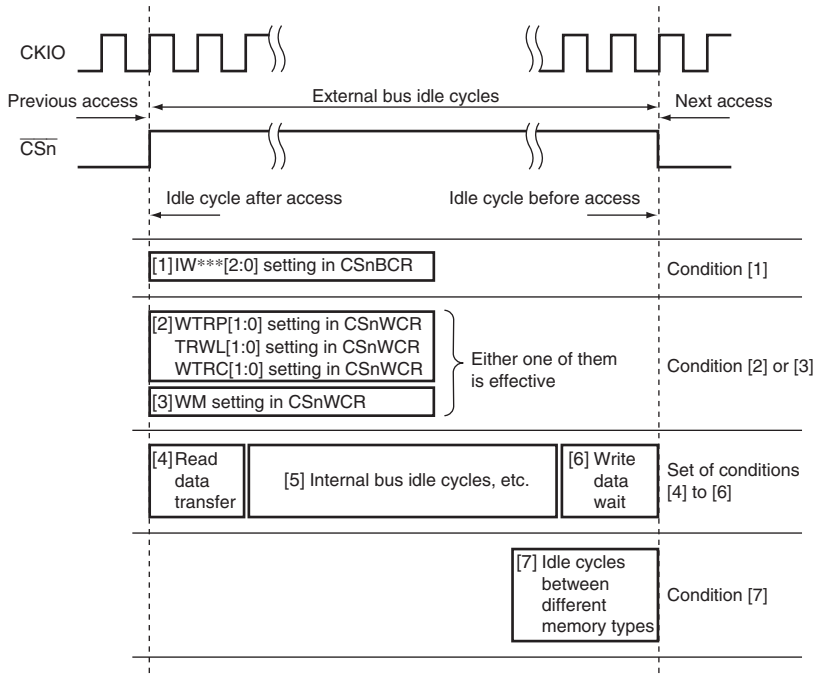
1. Continuous access cycles are write-read or write-write
2. Continuous access cycles are read-write for different spaces
3. Continuous access cycles are read-write for the same space
4. Continuous access cycles are read-read for different spaces
5. Continuous access cycles are read-read for the same space

For the specification of the number of idle cycles between access cycles described above, refer to the description of each register.
Besides the idle cycles between access cycles specified by the registers, idle cycles must be inserted to interface with the internal bus or to obtain the minimum pulse width for a multiplexed pin ($\overline{\text{WEn}}$). The following gives detailed information about the idle cycles and describes how to estimate the number of idle cycles.
The number of idle cycles on the external bus from $\overline{\text{CSn}}$ negation to $\overline{\text{CSn}}$ or $\overline{\text{CSm}}$ assertion is described below.
There are seven conditions that determine the number of idle cycles on the external bus as shown in Table 8.18. The effects of these conditions are shown in Figure 8.40.

Table 8.18 Conditions for Determining Number of Idle Cycles

No.	Condition	Description	Range	Note
[1]	IW***[2:0] in CSnBCR	These bits specify the number of idle cycles for access. The number of idle cycles can be specified independently for each combination of the previous and next cycles. For example, in the case where reading CS1 space followed by reading other CS space, the bits IWRRD[2:0] in CS1BCR should be set to B'100 to specify six or more idle cycles. This condition is effective only for access cycles other than single address transfer and generates idle cycles after the access is completed.	0 to 12	Do not set 0 for the number of idle cycles between memory types which are not allowed to be accessed successively.
[2]	SDRAM-related bits in CSnWCR	These bits specify precharge completion and startup wait cycles and idle cycles between commands for SDRAM access. This condition is effective only for SDRAM access and generates idle cycles after the access is completed	0 to 3	Specify these bits in accordance with the specification of the target SDRAM.
[3]	WM in CSnWCR	This bit enables or disables external $\overline{\text{WAIT}}$ pin input for the memory types other than SDRAM. When this bit is cleared to 0 (external $\overline{\text{WAIT}}$ enabled), one idle cycle is inserted to check the external $\overline{\text{WAIT}}$ pin input after the access is completed. When this bit is set to 1 (disabled), no idle cycle is generated.	0 or 1	
[4]	Read data transfer cycle	One idle cycle is inserted after a read access is completed. This idle cycle is not generated for the first or middle cycles in divided access cycles. This is neither generated when the HW[1:0] bits in CSnWCR are not B'00.	0 or 1	One idle cycle is always generated after a read cycle with SDRAM.
[5]	Internal bus idle cycles, etc.	External bus access requests from the CPU or the direct memory access controller and their results are passed through the internal bus. The external bus enters idle state during internal bus idle cycles or while a bus other than the external bus is being accessed. This condition is not effective for divided access cycles, which are generated by the bus state controller when the access size is larger than the external data bus width.	0 or larger	The number of internal bus idle cycles may not become 0 depending on the CPU: internal bus: CKIO
[6]	Write data wait cycles	During write access, a write cycle is executed on the external bus only after the write data becomes ready. This write data wait period generates idle cycles before the write cycle. Note that when the previous cycle is a write cycle and the internal bus idle cycles are shorter than the previous write cycle, write data can be prepared in parallel with the previous write cycle and therefore, no idle cycle is generated (write buffer effect).	0 or 1	For write → write or write → read access cycles, successive access cycles without idle cycles may be available due to the write buffer effect described in the left column. If successive access cycles without idle cycles are not allowed, specify the minimum number of idle cycles between access cycles through CSnBCR.
[7]	Idle cycles between different memory types	To ensure the minimum pulse width on the signal-multiplexed pins, idle cycles may be inserted before access after memory types are switched. For some memory types, idle cycles are inserted even when memory types are not switched.	0 to 2	The number of idle cycles depends on the target memory types. See Table 8.19.

In the above conditions, a total of four conditions, that is, condition [1], condition [2] or [3] (either one is effective), a set of conditions [4] to [6] (these are generated successively, and therefore the sum of them should be taken as one set of idle cycles), and condition [7] are generated at the same time. The maximum number of idle cycles among these four conditions become the number of idle cycles on the external bus. To ensure the minimum idle cycles, be sure to make register settings for condition [1].



Note: A total of four conditions (condition [1], condition [2] or [3], a set of conditions [4] to [6], and condition [7]) generate idle cycle at the same time. Accordingly, the maximum number of cycles among these four conditions become the number of idle cycles.

Figure 8.40 Idle Cycle Conditions

Table 8.19 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types

	Next Cycle						
Previous Cycle	**SRAM**	**Burst ROM (Asynchronous)**	**MPX-I/O**	**Byte SRAM (BAS = 0)**	**Byte SRAM (BAS = 1)**	**SDRAM**	**Burst ROM (Synchronous)**
SRAM	0	0	1	0	0/1*	0/1*	0
Burst ROM (asynchronous)	0	0	1	0	0/1*	0/1*	0
MPX-I/O	1	1	0	1	1	1	1
Byte SRAM (BAS = 0)	0	0	1	0	0/1*	0/1*	0
Byte SRAM (BAS = 1)	0/1*	0/1*	1/2*	0/1*	0	0	0/1*
SDRAM	1	1	2	1	0	0	1
Burst ROM (synchronous)	0	0	1	0	1	1	0

Note: * The number of idle cycles is determined by the setting of bits HW[1:0] in the CSnWCR register for the previous cycle. The values on the left and right sides of the virgules show the numbers of idle cycles when HW[1:0] ≠ B'00 and HW[1:0] = B'00, respectively. If the memory connected to the CSn space in the previous cycle is of a type for which bits HW[1:0] in the CSnWCR register are ineffective, the number of idle cycles will be the value on the right side.

8.5.11 Others

(1) Reset

This module can be initialized completely only at power-on reset. At power-on reset, all signals are negated and data output buffers are turned off regardless of the bus cycle state after the internal reset is synchronized with the internal clock. All control registers are initialized. In software standby and sleep, control registers of the bus state controller are not initialized.

(2) Caution on Write Buffer

Since the bus state controller incorporates a one-stage write buffer, it can execute an access via the internal bus before the previous external bus cycle is completed in a write cycle. If the on-chip module is read or written after the external low-speed memory is written, the on-chip module can be accessed before the completion of the external low-speed memory write cycle.

In read cycles, the CPU is placed in the wait state until read operation has been completed. To continue the process after the data write to the device has been completed, perform a dummy read to the same address to check for completion of the write before the next process to be executed.

The write buffer of the bus state controller functions in the same way for an access by a bus master other than the CPU such as the direct memory access controller. Accordingly, to perform DMA transfers, the next read cycle is initiated before the previous write cycle is completed. Note, however, that if both the DMA source and destination addresses exist in external memory space, the next read cycle will not be initiated until the previous write cycle is completed.

Changing the registers in this module while the write buffer is operating may disrupt correct write access. Therefore, do not change the registers in this module immediately after a write access. If this change becomes necessary, do it after executing a dummy read of the write data.

(3) On-Chip Peripheral Module Access

To access an on-chip module register, two or more peripheral module clock (P0φ or P1φ) cycles are required.

When the CPU writes data to the internal peripheral registers, the CPU performs the succeeding instructions without waiting for the completion of writing to registers.

For example, a case is described here in which the system is transferring to the software standby mode for power savings. To make this transition, the WFI instruction must be performed after setting the STBY bit in the STBCR1 register to 1. However a dummy read of the STBCR1 register is required before executing the WFI instruction. If a dummy read is omitted, the CPU executes the WFI instruction before the STBY bit is set to 1, thus the system enters sleep mode not software standby mode. A dummy read of the STBCR1 register is indispensable to complete writing to the STBY bit.

To reflect the change by internal peripheral registers while performing the succeeding instructions, execute a dummy read of registers to which write instruction is given and then perform the succeeding instructions.

9. Direct Memory Access Controller

The direct memory access controller can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

9.1 Features

- Number of channels selectable: 16 channels (CH0 to CH15). Only the CH0 channel can receive external requests.
- 4-Gbyte address space (according to the architecture)
- Transfer data size: Byte, two bytes, four bytes, eight bytes, 16 bytes, 32 bytes, 64 bytes, and 128 bytes
- Maximum transfer count: 2^{32} - 1 bytes
- Address mode: Dual address mode
- Transfer requests: Can be selected from the three types of external request, on-chip peripheral module request, and auto request (software trigger)
  The following modules can issue on-chip peripheral module requests.
  —Serial communication interface with FIFO: 10 sources
  —A/D converter: 1 source
  —Multi-function timer pulse unit 2: 5 sources
  —USB2.0 host/function module: 4 sources
  —Serial sound interface: 7 sources
  —Renesas SPDIF interface: 2 sources
  —CD-ROM decoder: 1 source (RZ/A1L only)
  —SD host interface: 4 sources
  —MMC host interface: 2 sources
  —Renesas serial peripheral interface: 6 sources
  —IEBus™ controller: 2 sources (RZ/A1L only)
  —OS timer: 2 sources
  —SCUX: 8 sources
  —Media local bus: 1 source (RZ/A1L only)
  —Serial communication interface: 4 sources
  —I^2C bus interface: 8 sources
  —LIN interface: 2 sources (RZ/A1L only)
- Transfer mode: Single transfer mode and block transfer mode are selectable.
- Priority: The channel priority levels within channels 0 to 7 and within channels 8 to 15 are selectable between fixed mode and round-robin mode (the channel priority level between the group of channels 0 to 7 and the group of channels 8 to 15 is round-robin mode).
- Interrupt request: An interrupt request can be sent to the CPU on completion of data transfer (DMA transfer end interrupt per channel) or on occurrence of a transfer error (DMA error interrupt).
- External request detection: Low level detection, high level detection, rising edge detection, and falling edge detection are selectable for DREQ input detection.
- The DMA registers have a continuous execution function that allows the next DMA transfer to be executed continuously by making settings for the next DMA transfer during execution of the current DMA transfer. This continuous execution function can be enabled or disabled independently in each channel.
- Link mode: In this mode, the setting data (descriptor data) located in the memory by the CPU is automatically retrieved by the DMAC, and DMA transfer is performed according to those values.
- Buffer sweep: If an ongoing DMA transfer is forced to end, the data already retrieved into the buffer can be output before DMA transfer ends.

- Interval: A specific DMA transfer interval can be specified to adjust the bus occupancy.

9.2 Input/Output Pins

Table 9.1 lists the pin configuration. This module has pins for a single channel (CH0) as the external bus use.

Table 9.1 Pin Configuration

Channel	Name	Pin Name	I/O	Function
0	DMA transfer request	DREQ0	Input	DMA transfer request input from an external device to channel 0
	DMA transfer request acknowledge	DACK0	Output	DMA transfer request acknowledge output from channel 0 of this module
	DMA transfer end	TEND0	Output	DMA transfer end output for channel 0 of this module

Note 1. For the active level of DACK0 and TEND0, refer to section 8, Bus State Controller.

9.3 Register Configuration

The register configuration is shown in the figure below.

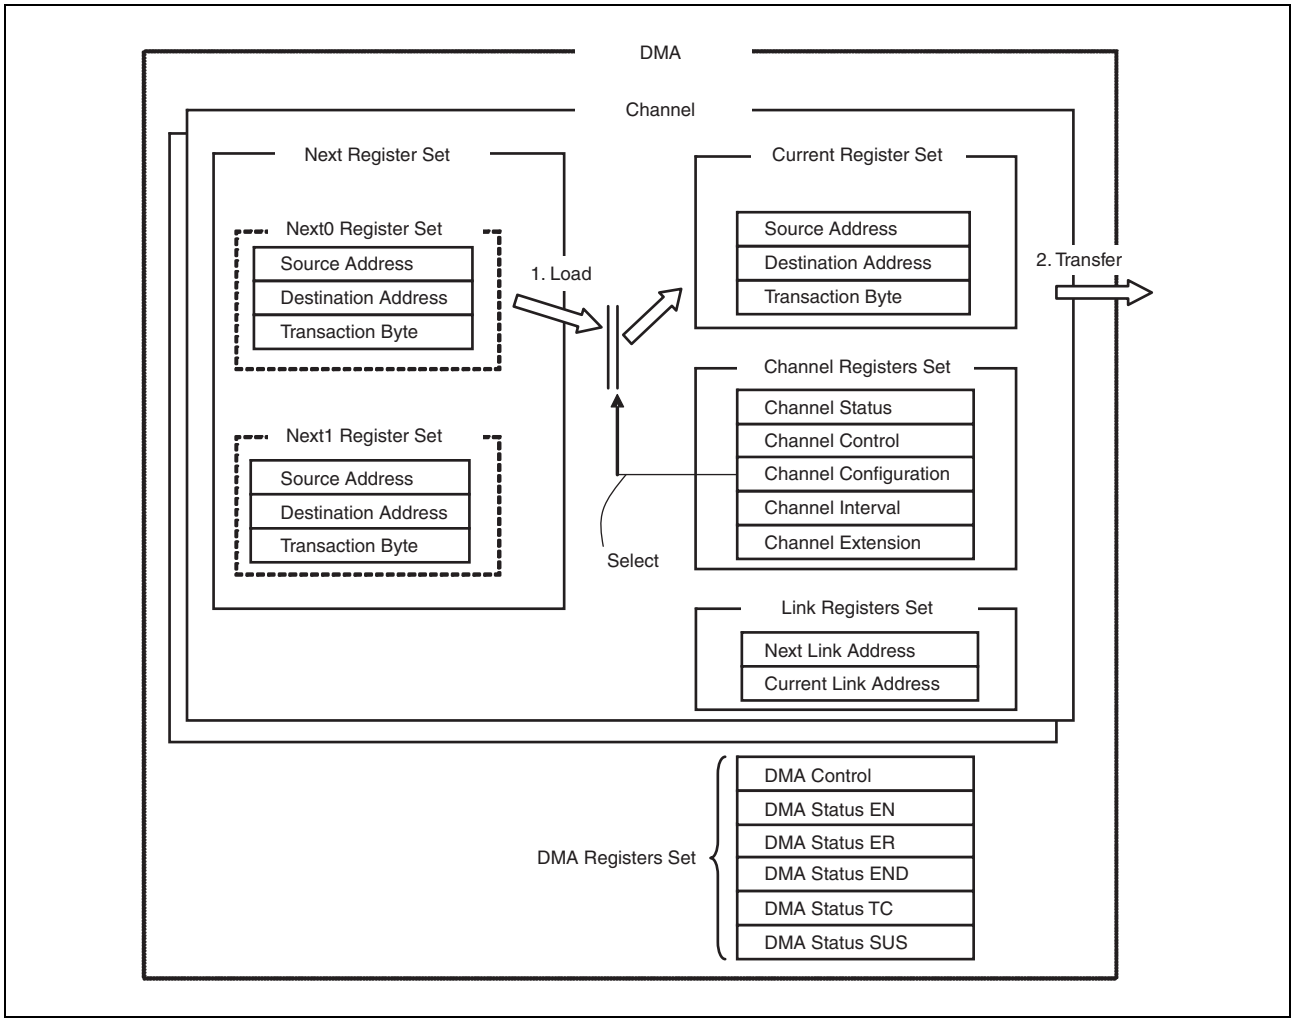


Figure 9.1 Register Configuration

(a) Next Register Set

This register set is used to set the source address, destination address, and transfer byte count of the DMA transaction to be executed next.

It consists of the Next0 Register Set and the Next1 Register Set.
In register mode, set this register set by using software. In link mode, the descriptor read data is automatically set in the Next0 Register Set.
These register set values are loaded to the Current Register Set and used for DMA transfer.

(b) Current Register Set

This register set indicates the source address, destination address, and transfer byte count of the currently executed DMA transaction.
The values are loaded from the Next0/1 Register Set (register mode) or from the descriptor read data (link mode). The user cannot write directly to this register set.
The register set is automatically updated each time a DMA transaction is executed.

(c) Channel Register Set

This register set is used to make the DMA transfer settings.
The settings to be made with this register set include channel status indication, channel control, DMA transaction setting, and DMA transaction interval.

(d) Link Register Set

This register set consists of a register that sets the address of the descriptor to be loaded next in link mode (Next Link Address Register) and a register that indicates the address of the currently executed descriptor (Current Link Address Register).
The Current Link Address Register is automatically updated when a descriptor is read. The user cannot write directly to this register set.

(e) DMA Register Set

This register set consists of a register that controls DMA as a whole and registers that indicate the status of the corresponding channels. It enables channel priority control as well as the monitoring of the channel status (EN, ER, END, TC, and SUS).

(f) Extended Resource Selector Register Set

This register set is used to select the on-chip peripheral module to perform DMA transfer and the external request.

9.4 Register Descriptions

Table 9.2 lists the register configuration. There are eleven control registers and five status registers for each channel, and twelve common control registers are used by all channels. In addition, there is one extension resource selector per two channels. Each channel number is expressed in the register names, as in N0SA_0 for N0SA in channel 0.

Table 9.2 Register Configuration

Channel	Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
0	Next0 source address register 0	N0SA_0	RW	H'00000000	H'E8200000	32
	Next0 destination address register 0	N0DA_0	RW	H'00000000	H'E8200004	32
	Next0 transaction byte register 0	N0TB_0	RW	H'00000000	H'E8200008	32
	Next1 source address register 0	N1SA_0	RW	H'00000000	H'E820000C	32
	Next1 destination address register 0	N1DA_0	RW	H'00000000	H'E8200010	32
	Next1 transaction byte register 0	N1TB_0	RW	H'00000000	H'E8200014	32
	Current source address register 0	CRSA_0	R	H'00000000	H'E8200018	32
	Current destination address register 0	CRDA_0	R	H'00000000	H'E820001C	32
	Current transaction byte register 0	CRTB_0	R	H'00000000	H'E8200020	32
	Channel status register 0	CHSTAT_0	R	H'00000000	H'E8200024	32
	Channel control register 0	CHCTRL_0	RW	H'00000000	H'E8200028	32
	Channel configuration register 0	CHCFG_0	RW	H'00000000	H'E820002C	32

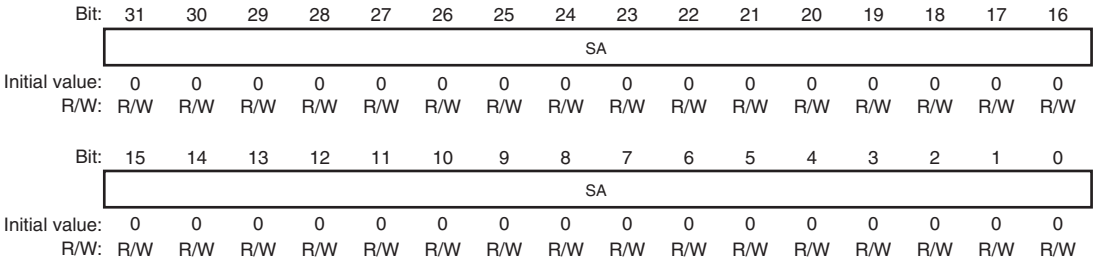
9.4.1 Next Source Address Register n (N0SA_n, N1SA_n)

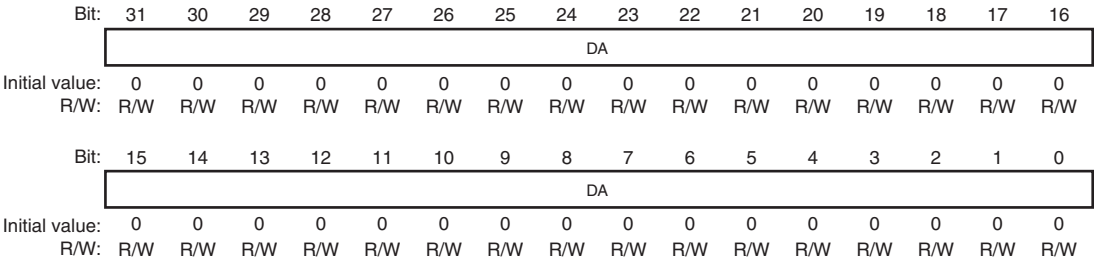
This register sets the DMA transfer source address (32 bits) of DMA channel n (n = 0 to 15) which is to be executed next.
N0SA_n is for the Next0 Register Set, and N1SA_n is for the Next1 Register Set.
In register mode, set this register set by using software. In link mode, the descriptor read data is automatically set in the Next0 Register Set.
These register set values are loaded to the Current Register Set and used for DMA transfer.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SA	All 0	R/W	Source Address Sets the start address of the DMA transfer source.

9.4.2 Next Destination Address Register n (N0DA_n, N1DA_n)

This register sets the DMA transfer destination address (32 bits) of DMA channel n (n = 0 to 15) which is to be executed next.
N0DA_n is for the Next0 Register Set, and N1DA_n is for the Next1 Register Set.
In register mode, set this register set by using software. In link mode, the descriptor read data is automatically set in the Next0 Register Set.
These register set values are loaded to the Current Register Set and used for DMA transfer.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DA	All 0	R/W	Destination Address Sets the start address of the DMA transfer destination.

9.4.3 Next Transaction Byte Register n (N0TB_n, N1TB_n)

This register sets the total transfer byte count (DMA transaction) of DMA channel (n = 0 to 15) which is to be executed next.
N0TB_n is for the Next0 Register Set, and N1TB_n is for the Next1 Register Set.
In register mode, set this register set by using software. In link mode, the descriptor read data is automatically set in the Next0 Register Set.
These register set values are loaded to the Current Register Set and used for DMA transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TB	All 0	R/W	Transaction Byte Sets the total transfer byte count. Caution: Do not start a DMA transaction with 0 set in this register.

9.4.4 Current Source Address Register (CRSA_n)

This register indicates the DMA transfer source address of DMA channel n (n = 0 to 15).
The values are loaded from the Next0/1 Register Set in register mode or from the descriptor read data in link mode. You cannot write to this register set using software.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRSA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	CRSA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CRSA	All 0	R	Current Source Address Register Indicates the read address of the next DMA transaction. The value automatically increments during the DMA transaction. (The value is fixed when 1 is set in SAD of the CHCFG_n register.) The value increments when a read transfer starts. Read this register after DMA stops (0 is set in EN of the CHSTAT_n register). (Any value obtained during the DMA operation should be handled as a reference value.)

9.4.5 Current Destination Address Register (CRDA_n)

This register indicates the DMA transfer destination address of DMA channel n (n = 0 to 15).
The values are loaded from the Next0/1 Register Set in register mode or from the descriptor read data in link mode. You cannot write to this register set using software.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRDA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRDA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CRDA	All 0	R	Current Destination Address Register Indicates the write address of the next DMA transaction. The value automatically increments during the DMA transaction. (The value is fixed when 1 is set in DAD of the CHCFG_n register.) The value increments when a write transfer starts. Read this register after DMA stops (0 is set in EN of the CHSTAT_n register). (Any value obtained during the DMA operation should be handled as a reference value.)

9.4.6 Current Transaction Byte Register (CRTB_n)

This register indicates the total transfer byte count of DMA channel n (n = 0 to 15). The value of this register becomes 0 when the transaction ends.
The values are loaded from the Next0/1 Register Set in register mode or from the descriptor read data in link mode. You cannot write to this register set using software.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRTB															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRTB															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CRTB	All 0	R	Current Transaction Byte Register Indicates the remaining transfer byte count of the currently executed DMA transaction. The value automatically decrements during the DMA transaction. The value decrements when a write transfer is completed. Read this register after DMA stops (0 is set in EN of the CHSTAT_n register). (Any value obtained during the DMA operation should be handled as a reference value.)

9.4.7 Channel Status Register n (CHSTAT_n)

This register indicates the status of DMA channel n (n = 0 to 15).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	INTMSK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	MODE	DER	DW	DL	SR	TC	END	ER	SUS	TACT	RQST	EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
16	INTMSK	0	R	Indicates the temporary mask status of the DMA transfer end interrupt. 1: Masked temporarily 0: Unmasked temporarily Set condition(s): • When SETINTMSK (CHCTRL_n) is set to 1 Reset condition(s): • When CLRINTMSK (CHCTRL_n) is set to 1 • When SWRST (CHCTRL_n) is set to 1
15 to 12	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
11	MODE	0	R	DMA Mode Indicates the DMA mode. It corresponds to the value set in the DMS bit of the CHCFG_n register. 0: Register mode 1: Link mode
10	DER	0	R	Descriptor Error Indicates whether the link valid value of the read descriptor is invalid (LV = 0) (this is not dependent on the DIM level of the descriptor). If a descriptor error has occurred, the transfer is stopped but no DMA error interrupt occurs. 0: Descriptor Error not detected 1: Descriptor Error detected Set condition(s): • When the LV value loaded with the descriptor in link mode is 0 Reset condition(s): • When SWRST (CHCTRL_n) is set to 1
9	DW	0	R	Descriptor WriteBack Indicates the descriptor writeback status. The bit maintains 1 if a bus error is received during descriptor writeback. 0: Operation other than writeback is being performed for the header in link mode. 1: (ER = 0) Writeback is being performed for the header in link mode. (ER = 1) A bus error occurs during writeback for the header in link mode. Set condition(s): • When header writeback in link mode starts Reset condition(s): • When header writeback in link mode ends with an OK response • When SWRST (CHCTRL_n) is set to 1

Bit	Bit Name	Initial Value	R/W	Description
8	DL	0	R	Descriptor Load Indicates whether the descriptor is being loaded. The bit maintains 1 if a bus error is received during descriptor load. 0: Operation other than descriptor load 1: (ER = 0) Descriptor load is in progress in link mode. (ER = 1) A bus error occurs during descriptor load in link mode. Set condition(s): • When descriptor load in link mode starts Reset condition(s): • When descriptor load in link mode ends with an OK response • When SWRST (CHCTRL_n) is set to 1
7	SR	0	R	Selected Register Set Indicates the register set currently selected in register mode. 0: Next0 Register Set 1: Next1 Register Set Set condition(s): • When RSEL (CHCFG_n) is set to 1 Reset condition(s): • When RSEL (CHCFG_n) is set to 0
6	TC	0	R	Terminal Count Indicates whether the DMA transaction is completed. 0: DMA transfer not completed 1: DMA transfer completed Set condition(s): • When data equivalent to the total transfer byte count set in the CRTB register has been transferred in register mode • When data equivalent to the total transfer byte count set in the CRTB register has been transferred in link mode, with 1 set in WBD of the descriptor header • When descriptor writeback is completed in link mode, with 0 set in WBD of the descriptor header Clear condition(s): • When the CLRTC (CHCTRL_n) bit is set to 1 • When the SWRST (CHCTRL_n) bit is set to 1
5	END	0	R	DMAEND Interrupted Indicates whether the DMA transaction is completed and whether the DMA transfer end interrupt has occurred. 0: DMA transfer not completed 1: DMA transfer completed Set condition(s): • When one of the set conditions for the TC bit is met and 0 is set in DEM of the CHCFG_n register • When the descriptor is read in link mode and both LV of the header and DIM are set to 0 Clear condition(s): • When CLREND (CHCTRL_n) is set to 1 • When SWRST (CHCTRL_n) is set to 1
4	ER	0	R	Error bit Indicates that a DMA error interrupt has occurred because an error response has been received from the transfer source or destination and a bus error has occurred during the DMA transfer. 0: No bus error has occurred 1: A DMA error interrupt has occurred due to a bus error Set condition(s): • When a bus error has occurred during a bus cycle Clear condition(s): • When SWRST (CHCTRL_n) is set to 1

Bit	Bit Name	Initial Value	R/W	Description
3	SUS	0	R	Suspend Indicates whether the channel is suspended. 0: Channel_n not suspended 1: Channel_n suspended Set condition(s): • When SETSUS (CHCTRL_n) is set to 1 during a DMA transfer on Channel_n, creating a SUSPEND status internally Clear condition(s): • When CLRSUS (CHCTRL_n) is set to 1 • When CLREN (CHCTRL_n) is set to 1
2	TACT	0	R	Transaction Active Indicates whether the DMAC is active. This bit is intended to check that the channel is completely inactive. 0: DMA on Channel_n inactive 1: DMA on Channel_n active Set condition(s): • When a DMA transaction starts on Channel_n Clear condition(s): • When a DMA transaction is completed
1	RQST	0	R	Request Indicates whether a transfer request is being received. 0: DMA transfer request not being received 1: DMA transfer request being received Set condition(s): • When the STG bit (CHCTRL_n) is set to 1 (auto request) • When a transfer request is received from the DMA request source set in the CHCFG_n register Clear condition(s): • When SWRST (CHCTRL_n) is set to 1 • When CLRRQ (CHCTRL_n) is set to 1 • When a transfer is executed on the side specified by REQD (CHCFG_n) in single transfer mode (TM = 0). • When all DMA transactions are completed in register mode (the transaction ends with REN set to 0) • When the DMA transfer of the last descriptor (LE = 1) is completed in link mode • When descriptor read stops (LV = 0) in link mode • When a DMA transaction is completed in link mode while DEM is set to 0 • When a bus error is received due to an error response
0	EN	0	R	Enable Indicates whether the operation of DMA channel n is enabled or disabled. 0: Operation disabled 1: Operation enabled Set condition(s): • When SETEN (CHCTRL_n) is set to 1 Clear condition(s): • When SWRST (CHCTRL_n) is set to 1 • When CLREN (CHCTRL_n) is set to 1 • When a bus error is received due to an error response during the transfer • When all DMA transactions are completed in register mode (the transaction ends with REN set to 0) • When the DMA transfer of the last descriptor (LE = 1) is completed in link mode (writeback when WBD is set to 0) • When descriptor read stops (LV = 0) in link mode

<Caution> If the ER bit is set to 1 for any transfer, the whole transfer should be handled as invalid.
To suspend a DMA transaction, mask or clear the transfer request or clear the Enable bit (for the procedure, see section 9.7.11 (2) Transfer Stop).
If you make a transfer request from an on-chip peripheral module or the external DREQ input concurrently with an auto request (by setting 1 in the STG bit) for the same one channel, you cannot identify the trigger source that takes effect. Make sure that only one of these transfer requests is used in the system.
When transfer is requested by an auto request, wait for the last requested DMA transfer to complete (use the Current Register or other data to check the status) before setting the STG bit for the next transfer request.

9.4.8 Channel Control Register n (CHCTRL_n)

This register controls the DMA transfer operation on DMA channel n (n = 0 to 15).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	CLR SUS	SET SUS	-	CLRTC	CLR END	CLRRQ	SWRST	STG	CLREN	SETEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
17	CLRINTMSK	0	R/W	When this bit is set to 1, the mask of the DMA transfer end interrupt is cleared. Also, the INTMSK bit of the CHSTAT_n register is set to 0. If the mask is cleared when 1 is set in both LVINT of the DCTRL register and END of the CHSTAT_n register, the DMA transfer end interrupt becomes active. (It does not become active when 0 is set in LVINT.) A read operation results in 0 being read. 1: Clears the mask set by SETINTMSK. 0: Does not affect the operation.
16	SETINTMSK	0	R/W	When this bit is set to 1, the DMA transfer end interrupt is temporarily masked. Also, the INTMSK bit of the CHSTAT_n register is set to 1. A read operation results in 0 being read. 1: Masks the DMA transfer end interrupt. 0: Does not affect the operation.
15 to 10	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
9	CLRSUS	0	R/W	Clear Suspend Clears the suspend status. Setting this bit to 1 when 1 is set in SUS of the CHSTAT_n register can clear the suspend status. An attempt to read this bit results in 0 being read. 1: Clears the suspend status of the current DMA transfer. 0: Does not affect the operation.
8	SETSUS	0	R/W	Set Suspend Suspends the current DMA transfer. Setting this bit to 1 when 1 is set in EN of the CHSTAT_n register can suspend the current DMA transfer. An attempt to read this bit results in 0 being read. 1: Suspends the current DMA transfer. 0: Does not affect the operation.
7	—	0	R	Reserved area. Set 0. A read operation results in 0 being read.
6	CLRTC	0	R/W	Clear TC bit Setting this bit to 1 can clear the TC bit of the CHSTAT_n register. An attempt to read this bit results in 0 being read. 1: Clears the TC bit. 0: Does not affect the operation.
5	CLREND	0	R/W	Clear End bit Setting this bit to 1 can clear the END bit of the CHSTAT_n register. Also, the DMA transfer end interrupt is cleared. An attempt to read this bit results in 0 being read. 1: Clears the END bit. 0: Does not affect the operation.
4	CLRRQ	0	R/W	Clear Request bit Setting this bit to 1 can clear the RQST bit of the CHSTAT_n register. An attempt to read this bit results in 0 being read. 1: Clears the RQST bit. 0: Does not affect the operation.

Bit	Bit Name	Initial Value	R/W	Description
3	SWRST	0	R/W	Software Reset Setting this bit to 1 can clear the channel status register (CHSTAT_n). When setting this bit to 1, make sure that both the EN bit and TACT bit are set to 0. An attempt to read this bit results in 0 being read. 1: Resets the channel status register. 0: Does not affect the operation.
2	STG	0	R/W	Software Trigger Setting this bit to 1 sets an auto request. If this bit is set at the same time the SWRST bit is set, the clear operation by the SWRST bit takes precedence. An attempt to read this bit results in 0 being read. 1: Sets a transfer request triggered by an auto request (sets 1 in the RQST bit). 0: Does not affect the operation.
1	CLREN	0	R/W	Clear Enable Setting this bit to 1 can clear the EN bit (for details, see section 9.7.11 (2) Transfer Stop). An attempt to read this bit results in 0 being read. 1: Stops the DMA transfer (clears the EN bit). 0: Does not affect the operation.
0	SETEN	0	R/W	Set Enable Enables a DMA transfer on DMA channel n. If this bit is set at the same time the SWRST bit is set, the clear operation by the SWRST bit takes precedence and the transfer does not start. An attempt to read this bit results in 0 being read. 1: Enables a DMA transfer (sets 1 in the EN bit). 0: Does not affect the operation.

9.4.9 Channel Configuration Register n (CHCFG_n)

This register controls the DMA transfer operation on DMA channel n (n = 0 to 15).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDS[3:0]				-	AM[2:0]			-	LVL	HIEN	LOEN	REQD	SEL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	DMS	0	R/W	DMA Mode Select Sets the DMA mode. 0: Register mode (initial value) 1: Link mode
30	REN	0	R/W	Register Set Enable After a DMA transaction is completed, DMA transfers are continued using the Next Register Set selected by RSEL. This bit is valid only in register mode. 0: Does not continue DMA transfers. 1: Continues DMA transfers. Set condition(s): • When 1 is written to this bit Clear condition(s): • When 0 is written to this bit • When a DMA transaction is completed, with REN set to 1
29	RSW	0	R/W	Register Select Switch Inverts RSEL automatically after a DMA transaction is completed. This bit is valid only in register mode. 0: Does not invert RSEL automatically after a DMA transaction (initial value). 1: Inverts RSEL automatically after a DMA transaction.
28	RSEL	0	R/W	Register Set Select Selects the Next Register Set to be executed next. This bit is valid only in register mode. When RSW is set to 1, this bit is inverted automatically when a DMA transaction is completed. 0: Executes the Next0 Register Set (initial value). 1: Executes the Next1 Register Set. Transition condition(s): • When a DMA transaction is completed, with RSW set to 1
27	SBE	0	R/W	Sweep Buffer Enable Selects whether to sweep (write) the data already read into the buffer and stop the DMA transfer if the Enable bit is cleared to 0 during a DMA transaction. The sweep mode is available only when REQD is set to 0. 0: Stops the DMA transfer without sweeping the buffer (initial value). 1: Stops the DMA transfer after sweeping the buffer.
26, 25	—	0	R	Reserved area. Set 0. A read operation results in 0 being read.
24	DEM	0	R/W	DMA Transfer End Interrupt Mask Masks the DMA transfer end interrupt for register mode transfer. If 1 is set in this bit when a DMA transfer end interrupt is output, the DMA transfer end interrupt signal is not asserted. In this case, DEM is cleared to 0 automatically. 0: Does not mask the DMA transfer end interrupt (initial value). 1: Masks the DMA transfer end interrupt. Clear condition(s): • When a DMA transaction is completed with DEM set to 1
23	—	0	R	Reserved area. Set 0. A read operation results in 0 being read.

Bit	Bit Name	Initial Value	R/W	Description
22	TM	0	R/W	Transfer Mode Sets the DMA transfer mode. 0: Single transfer mode (initial value) 1: Block transfer mode
21	DAD	0	R/W	Sets the destination address counting direction of DMA channel n. 0: Increment (initial value) 1: Fixed
20	SAD	0	R/W	Sets the source address counting direction of DMA channel n. 0: Increment (initial value) 1: Fixed
19 to 16	DDS [3:0]	0000	R/W	Destination Data Size Sets the DMA transfer size of the transfer destination.

Value	Size	Remark
0000	8 bits	Initial value
0001	16 bits	
0010	32 bits	
0011	64 bits	
0100	128 bits	
0101	256 bits	
0110	512 bits	
0111	1024 bits	
Other than the above	—	Setting prohibited

15 to 12	SDS [3:0]	0000	R/W	Source Data Size Sets the DMA transfer size of the transfer source.

Value	Size	Remark
0000	8 bits	Initial value
0001	16 bits	
0010	32 bits	
0011	64 bits	
0100	128 bits	
0101	256 bits	
0110	512 bits	
0111	1024 bits	
Other than the above	—	Setting prohibited

11	—	0	R	Reserved area. Set 0. A read operation results in 0 being read.
10 to 8	AM [2:0]	000	R/W	ACK Mode Sets the DMAACK output mode. 000: (initial value) 001: Level mode (active until the transfer request from an on-chip peripheral module or the external DREQ input becomes inactive) 01x: Bus cycle mode (active while the DMA transfer is in a bus cycle) 1xx: DMAACK not to be output (this setting should be made when an auto request is made by STG (CHCTRL_n))
7	—	0	R	Reserved area. Set 0. A read operation results in 0 being read.
6	LVL	0	R/W	Level Selects whether to detect a DMA request based on the level or edge of the signal. 0: Detects based on the edge (initial value). 1: Detects based on the level.

Bit	Bit Name	Initial Value	R/W	Description
5	HIEN	0	R/W	High Enable Selects whether to detect a DMA request using the High level or rising edge of the signal. When LVL = 0: HIEN = 1: Detects a request in response to the rising edge of the signal. HIEN = 0: Does not detect a request in response to the rising edge of the signal (initial value). When LVL = 1: HIEN = 1: Detects a request when the signal is at the High level. HIEN = 0: Does not detect a request even when the signal is at the High level (initial value).
4	LOEN	0	R/W	Low Enable Selects whether to detect a DMA request using the Low level or falling edge of the signal. When LVL = 0: LOEN = 1: Detects a request in response to the falling edge of the signal. LOEN = 0: Does not detect a request in response to the falling edge of the signal (initial value). When LVL = 1: LOEN = 1: Detects a request when the signal is at the Low level. LOEN = 0: Does not detect a request even when the signal is at the Low level (initial value).
3	REQD	0	R/W	Request Direction Selects whether DMAREQ selected by the SEL bit is the source or destination. This bit is also used to define when DMAACK is to become active. 0: Source; DMAACK is to become active when read (initial value). 1: Destination; DMAACK is to become active when written.
2 to 0	SEL[2:0]	000	R/W	These bits are used to set a DMAC channel. Set one of the following values so that the channel set by the SEL bits matches the CHCFG_n channel. 000: CH0/CH8 001: CH1/CH9 010: CH2/CH10 011: CH3/CH11 100: CH4/CH12 101: CH5/CH13 110: CH6/CH14 111: CH7/CH15

9.4.10 Channel Interval Register n (CHITVL_n)

This register sets the transfer interval for DMA channel n (n = 0 to 15).

For details, see section 9.7.9, Interval Count Function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ITVL															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
15 to 0	ITVL	All 0	R/W	Sets the channel transfer interval.

9.4.11 Channel Extension Register n (CHEXT_n)

This is an extension register for DMA channel n (n = 0 to 15).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCA[3:0]				-	DPR[2:0]			SCA[3:0]				-	SPR[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Set 0. A read operation results in 0 being read.
15 to 12	DCA[3:0]	0000	R/W	Destination CACHE Sets the value to be output to AWCACHE[3:0] for DMA write transfer. See Note 1 below.
11	—	0	R	Set 0. A read operation results in 0 being read.
10 to 8	DPR[2:0]	000	R/W	Destination PROT Sets the value to be output to AWPROT[2:0] for DMA write transfer. See Note 2 below.
7 to 4	SCA[3:0]	0000	R/W	Source CACHE Sets the value to be output to ARCACHE[3:0] for DMA read transfer. See Note 1 below.
3	—	0	R	Set 0. A read operation results in 0 being read.
2 to 0	SPR[2:0]	000	R/W	Source PROT Sets the value to be output to ARPROT[2:0] for DMA read transfer. See Note 2 below.

Note 1. Cache support: Bits SCA and DCA are used to change the settings.
When the transfer destination or source is not in the external bus space, set these bits to 0000.
Even when the transfer destination or source is in the external bus space but the secondary cache is not in use, set these bits to 0000. In this case, the DACK0 output and TEND0 output are issued in response to the DREQ0 transfer request.
When the secondary cache is in use in the external bus space, set CACHE[3:0].

Note 2. Protection unit support: Bits SPR and DPR are used to change the settings.

For the setting value, see AMBA AXI Protocol Specification from Arm Limited.

9.4.12 Next Link Address Register n (NXLA_n)

This is a 32-bit register that sets the link address of DMA channel n (n = 0 to 15).
For information about the link mode, see section 9.6.3, Link Mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NXLA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NXLA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	NXLA	All 0	R/W	Sets a link address. The low-order 2 bits are masked with 0s. Only an address aligned with a 4-byte boundary can be set.

9.4.13 Current Link Address Register n (CRLA_n)

This is a 32-bit register that indicates the link address of DMA channel n (n = 0 to 15).
For information about the link mode, see section 9.6.3, Link Mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRLA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRLA															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CRLA	All 0	R	Indicates the address of the currently executed descriptor.

9.4.14 DMA Control Register (DCTRL_0_7, DCTRL_8_15)

This register sets the transfer type for descriptor access and the arbitration between channels.
(DCTRL_0_7 is common for channels 0 to 7 and DCTRL_8_15 is common for channels 8 to 15.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LWCA				-	LWPR			LDCA				-	LDPR		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	LVINT	PR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	LWCA	0000	R/W	Link WriteBack CACHE Sets the value to be output to AWCACHE[3:0] during descriptor writeback in link mode. For the setting value, see Note in section 9.4.11, Channel Extension Register n (CHEXT_n).
27	—	0	R	Reserved area. Set 0. The initial value is 0.
26 to 24	LWPR	000	R/W	Link WriteBack PROT Sets the value to be output to AWPROT[2:0] during descriptor writeback in link mode. For the setting value, see AMBA AXI Protocol Specification from Arm Limited.
23 to 20	LDCA	0000	R/W	Link Descriptor CACHE Sets the value to be output to ARCACHE[3:0] during descriptor load in link mode. For the setting value, see Note in section 9.4.11, Channel Extension Register n (CHEXT_n).
19	—	0	R	Reserved area. Set 0. The initial value is 0.
18 to 16	LDPR	000	R/W	Link Descriptor PROT Sets the value to be output to ARPROT[2:0] during descriptor load in link mode. For the setting value, see AMBA AXI Protocol Specification from Arm Limited.
15 to 2	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
1	LVINT	0	R/W	Sets whether to use pulse output or level output for the DMA transfer end interrupt and DMA error interrupt. Set pulse output for this product. 0: Pulse output (initial value) 1: Level output
0	PR	0	R/W	Sets the transfer priority control mode between channels (see section 9.7.2, Priority Control for DMA Channels. 0: Fixed priority mode (initial value) 1: Round robin mode

9.4.15 DMA Status EN Register (DSTAT_EN_0_7)

This register indicates the EN bit status of the CHSTAT_n register (n = 0 to 7).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	EN7	EN6	EN5	EN4	EN3	EN2	EN1	EN0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	EN7	0	R	Indicates the EN bit status of DMA channel 7.
6	EN6	0	R	Indicates the EN bit status of DMA channel 6.
5	EN5	0	R	Indicates the EN bit status of DMA channel 5.
4	EN4	0	R	Indicates the EN bit status of DMA channel 4.
3	EN3	0	R	Indicates the EN bit status of DMA channel 3.
2	EN2	0	R	Indicates the EN bit status of DMA channel 2.
1	EN1	0	R	Indicates the EN bit status of DMA channel 1.
0	EN0	0	R	Indicates the EN bit status of DMA channel 0.

9.4.16 DMA Status EN Register (DSTAT_EN_8_15)

This register indicates the EN bit status of the CHSTAT_n register (n = 8 to 15).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	EN15	EN14	EN13	EN12	EN11	EN10	EN9	EN8
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	EN15	0	R	Indicates the EN bit status of DMA channel 15.
6	EN14	0	R	Indicates the EN bit status of DMA channel 14.
5	EN13	0	R	Indicates the EN bit status of DMA channel 13.
4	EN12	0	R	Indicates the EN bit status of DMA channel 12.
3	EN11	0	R	Indicates the EN bit status of DMA channel 11.
2	EN10	0	R	Indicates the EN bit status of DMA channel 10.
1	EN9	0	R	Indicates the EN bit status of DMA channel 9.
0	EN8	0	R	Indicates the EN bit status of DMA channel 8.

9.4.17 DMA Status ER Register (DSTAT_ER_0_7)

This register indicates the ER bit status of the CHSTAT_n register (n = 0 to 7).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	ER7	ER6	ER5	ER4	ER3	ER2	ER1	ER0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	ER7	0	R	Indicates the ER bit status of DMA channel 7.
6	ER6	0	R	Indicates the ER bit status of DMA channel 6.
5	ER5	0	R	Indicates the ER bit status of DMA channel 5.
4	ER4	0	R	Indicates the ER bit status of DMA channel 4.
3	ER3	0	R	Indicates the ER bit status of DMA channel 3.
2	ER2	0	R	Indicates the ER bit status of DMA channel 2.
1	ER1	0	R	Indicates the ER bit status of DMA channel 1.
0	ER0	0	R	Indicates the ER bit status of DMA channel 0.

9.4.18 DMA Status ER Register (DSTAT_ER_8_15)

This register indicates the ER bit status of the CHSTAT_n register (n = 8 to 15).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	ER15	0	R	Indicates the ER bit status of DMA channel 15.
6	ER14	0	R	Indicates the ER bit status of DMA channel 14.
5	ER13	0	R	Indicates the ER bit status of DMA channel 13.
4	ER12	0	R	Indicates the ER bit status of DMA channel 12.
3	ER11	0	R	Indicates the ER bit status of DMA channel 11.
2	ER10	0	R	Indicates the ER bit status of DMA channel 10.
1	ER9	0	R	Indicates the ER bit status of DMA channel 9.
0	ER8	0	R	Indicates the ER bit status of DMA channel 8.

9.4.19 DMA Status END Register (DSTAT_END_0_7)

This register indicates the END bit status of the CHSTAT_n register (n = 0 to 7).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	END7	0	R	Indicates the END bit status of DMA channel 7.
6	END6	0	R	Indicates the END bit status of DMA channel 6.
5	END5	0	R	Indicates the END bit status of DMA channel 5.
4	END4	0	R	Indicates the END bit status of DMA channel 4.
3	END3	0	R	Indicates the END bit status of DMA channel 3.
2	END2	0	R	Indicates the END bit status of DMA channel 2.
1	END1	0	R	Indicates the END bit status of DMA channel 1.
0	END0	0	R	Indicates the END bit status of DMA channel 0.

9.4.20 DMA Status END Register (DSTAT_END_8_15)

This register indicates the END bit status of the CHSTAT_n register (n = 8 to 15).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	END15	0	R	Indicates the END bit status of DMA channel 15.
6	END14	0	R	Indicates the END bit status of DMA channel 14.
5	END13	0	R	Indicates the END bit status of DMA channel 13.
4	END12	0	R	Indicates the END bit status of DMA channel 12.
3	END11	0	R	Indicates the END bit status of DMA channel 11.
2	END10	0	R	Indicates the END bit status of DMA channel 10.
1	END9	0	R	Indicates the END bit status of DMA channel 9.
0	END8	0	R	Indicates the END bit status of DMA channel 8.

9.4.21 DMA Status TC Register (DSTAT_TC_0_7)

This register indicates the TC bit status of the CHSTAT_n register (n = 0 to 7).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	TC7	0	R	Indicates the TC bit status of DMA channel 7.
6	TC6	0	R	Indicates the TC bit status of DMA channel 6.
5	TC5	0	R	Indicates the TC bit status of DMA channel 5.
4	TC4	0	R	Indicates the TC bit status of DMA channel 4.
3	TC3	0	R	Indicates the TC bit status of DMA channel 3.
2	TC2	0	R	Indicates the TC bit status of DMA channel 2.
1	TC1	0	R	Indicates the TC bit status of DMA channel 1.
0	TC0	0	R	Indicates the TC bit status of DMA channel 0.

9.4.22 DMA Status TC Register (DSTAT_TC_8_15)

This register indicates the TC bit status of the CHSTAT_n register (n = 8 to 15).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	TC15	0	R	Indicates the TC bit status of DMA channel 15.
6	TC14	0	R	Indicates the TC bit status of DMA channel 14.
5	TC13	0	R	Indicates the TC bit status of DMA channel 13.
4	TC12	0	R	Indicates the TC bit status of DMA channel 12.
3	TC11	0	R	Indicates the TC bit status of DMA channel 11.
2	TC10	0	R	Indicates the TC bit status of DMA channel 10.
1	TC9	0	R	Indicates the TC bit status of DMA channel 9.
0	TC8	0	R	Indicates the TC bit status of DMA channel 8.

9.4.23 DMA Status SUS Register (DSTAT_SUS_0_7)

This register indicates the SUS bit status of the CHSTAT_n register (n = 0 to 7).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	SUS7	SUS6	SUS5	SUS4	SUS3	SUS2	SUS1	SUS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	SUS7	0	R	Indicates the SUS bit status of DMA channel 7.
6	SUS6	0	R	Indicates the SUS bit status of DMA channel 6.
5	SUS5	0	R	Indicates the SUS bit status of DMA channel 5.
4	SUS4	0	R	Indicates the SUS bit status of DMA channel 4.
3	SUS3	0	R	Indicates the SUS bit status of DMA channel 3.
2	SUS2	0	R	Indicates the SUS bit status of DMA channel 2.
1	SUS1	0	R	Indicates the SUS bit status of DMA channel 1.
0	SUS0	0	R	Indicates the SUS bit status of DMA channel 0.

9.4.24 DMA Status SUS Register (DSTAT_SUS_8_15)

This register indicates the SUS bit status of the CHSTAT_n register (n = 8 to 15).
Even if you write to this register, the values of the individual bits do not change.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	SUS15	SUS14	SUS13	SUS12	SUS11	SUS10	SUS9	SUS8
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved area. Set 0. A read operation results in 0 being read.
7	SUS15	0	R	Indicates the SUS bit status of DMA channel 15.
6	SUS14	0	R	Indicates the SUS bit status of DMA channel 14.
5	SUS13	0	R	Indicates the SUS bit status of DMA channel 13.
4	SUS12	0	R	Indicates the SUS bit status of DMA channel 12.
3	SUS11	0	R	Indicates the SUS bit status of DMA channel 11.
2	SUS10	0	R	Indicates the SUS bit status of DMA channel 10.
1	SUS9	0	R	Indicates the SUS bit status of DMA channel 9.
0	SUS8	0	R	Indicates the SUS bit status of DMA channel 8.

9.4.25 DMA Extension Resource Selectors 0 to 7 (DMARS0 to DMARS7)

DMARS are 32-bit readable/writable registers that specify the DMA transfer sources from peripheral modules in each channel. DMARS0 is for channels 0 and 1, DMARS1 is for channels 2 and 3, and so on.

Table 9.4 shows the specifiable combinations.

DMARS can specify transfer requests to be accepted for the following triggers.

The following modules can issue on-chip peripheral module requests.

Serial communication interface with FIFO: 10 sources
A/D converter: 1 source
Multi-function timer pulse unit 2: 5 sources
USB2.0 host/function module: 4 sources
Serial sound interface: 7 sources
Renesas SPDIF interface: 2 sources
CD-ROM decoder: 1 source (RZ/A1L only)
SD host interface: 4 sources
MMC host interface: 2 sources
Renesas serial peripheral interface: 6 sources
IEBus™ controller: 2 sources (RZ/A1L only)
OS timer: 2 sources
SCUX: 8 sources
Media local bus: 1 source (RZ/A1L only)
Serial communication interface: 4 sources
I^2C bus interface: 8 sources
LIN interface: 2 sources (RZ/A1L only)

Some on-chip peripheral modules in this product use the same signal both for an interrupt request and for a DMA transfer request. If such a module is selected by a DMARS register, the signal works as a DMA transfer request signal and interrupt requests to the interrupt controller are masked. To enable the interrupt, clear the setting of DMARS (set all MID[6:0] and RID[1:0] to 0).

9.5 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request.

9.5.1 Transfer Flow

After the next source address register (N0SA_n/N1SA_n), next destination address register (N0DA_n/N1DA_n), next transaction byte register (N0TB_n/N1TB_n), channel control register (CHCTRL_n), channel configuration register (CHCFG_n), channel extension register (CHEXT_n), DMA control register (DCTRL_0_7/DCTRL_8_15), and DMA extension resource selector (DMARS) are set for the target transfer conditions, the DMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (EN = 0 and TACT = 0 in channel status register).
2. Clears the channel status register (set 1 in the SWRST bit of the channel control register).
3. Enables DMA transfer (set 1 in the SETEN bit of the channel control register).
4. When a transfer request comes and transfer is enabled, the DMAC transfers one transfer unit of data (depending on the DDS[3:0] and SDS[3:0] bit settings). For an auto request, the transfer begins automatically when 1 is set in the STG bit of the channel control register. The CRTB_n value will be decremented by 1 for each transfer.
5. If 0 is set in the REN bit of the channel configuration register when transfer has been completed for the specified count (when CRTB_n reaches 0), transfer ends normally. If the DEM bit of the channel configuration register is set to 0 at this time, a DMA transfer end interrupt is sent to the CPU. If the REN bit is 1 when CRTB_n reaches 0, transfer operations are continued with the values of N0SA_n/N1SA_n, N0DA_n/N1DA_n, and N0TB_n/N1TB_n set by the RSEL bit of the channel configuration register until there are no more transfer requests.
6. When an address error in the DMAC is generated, the transfer is stopped. Transfers are also stopped when 1 is set in the CLREN bit of CHCTRL_n.

9.5.2 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated in external devices and on-chip peripheral modules that are neither the transfer source nor destination. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. External request or on-chip peripheral module request is selected by the DMARS0 to DMARS7 registers.

(1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the STG bit in channel control register is set to 1, the transfer begins so long as the TACT bit in channel status register is 0.

(2) External Request Mode

In this mode a transfer is performed at the transfer request signal (DREQ0) of an external device of the LSI. When the DMA transfer is enabled, DMA transfer is performed upon a DREQ input.
Choose to detect DREQ0 by either the edge or level of the signal input with the LVL, HIEN, and LOEN bits in channel configuration register 0 as shown below. The source of the transfer request does not have to be the data transfer source or destination.
For the output level settings of the DACK0 and TEND0 pins, refer to section 8, Bus State Controller.

Table 9.3 Settings for External Request Detection

	CHCFG_0		
LVL	**HIEN**	**LOEN**	**Detection of External Request**
0	0	1	Falling edge detection
	1	0	Rising edge detection
1	0	1	Low level detection
	1	0	High level detection

When DREQ0 is accepted, the DREQ0 pin enters the request accept disabled state (non-sensitive period). After issuing an acknowledge DACK0 signal for the accepted DREQ0, the DREQ0 pin again enters the request accept enabled state.

(3) On-Chip Peripheral Module Request Mode

In this mode, the transfer is performed in response to the DMA transfer request signal from an on-chip peripheral module.

When a transfer request signal is sent in on-chip peripheral module request mode while DMA transfer is enabled, the DMA transfer is performed.

The DMA transfer request signals to be sent from on-chip peripheral modules or external pin input are listed in Table 9.4.

The transfer source or destination is fixed for some on-chip peripheral module requests. For details, see Table 9.4.

9.6 DMA Mode

9.6.1 Mode Setting

You can toggle between register mode and link mode, by using the DMS field of the CHCFG_n register.

Table 9.5 DMA Mode Setting

DMS (CHCFG_n)	Mode	Description
0	Register mode	A DMA transfer is executed using the values set in the Next Register Set.
1	Link mode	A DMA transfer is executed using the descriptor set in the Current register. The DMAC repeatedly loads the descriptor and executes the DMA transfer unless otherwise set by the descriptor or stopped by the control register.

9.6.2 Register Mode

In register mode, a DMA transfer is executed using the values set in the internal registers.
Two sets of the source address, destination address, and transfer byte count (Next0 Register Set and Next1 Register Set) can be set. It is possible to select the Next Register Set to be used for the DMA transfer, as well as to execute two Next Register Sets continuously for the DMA transfer.

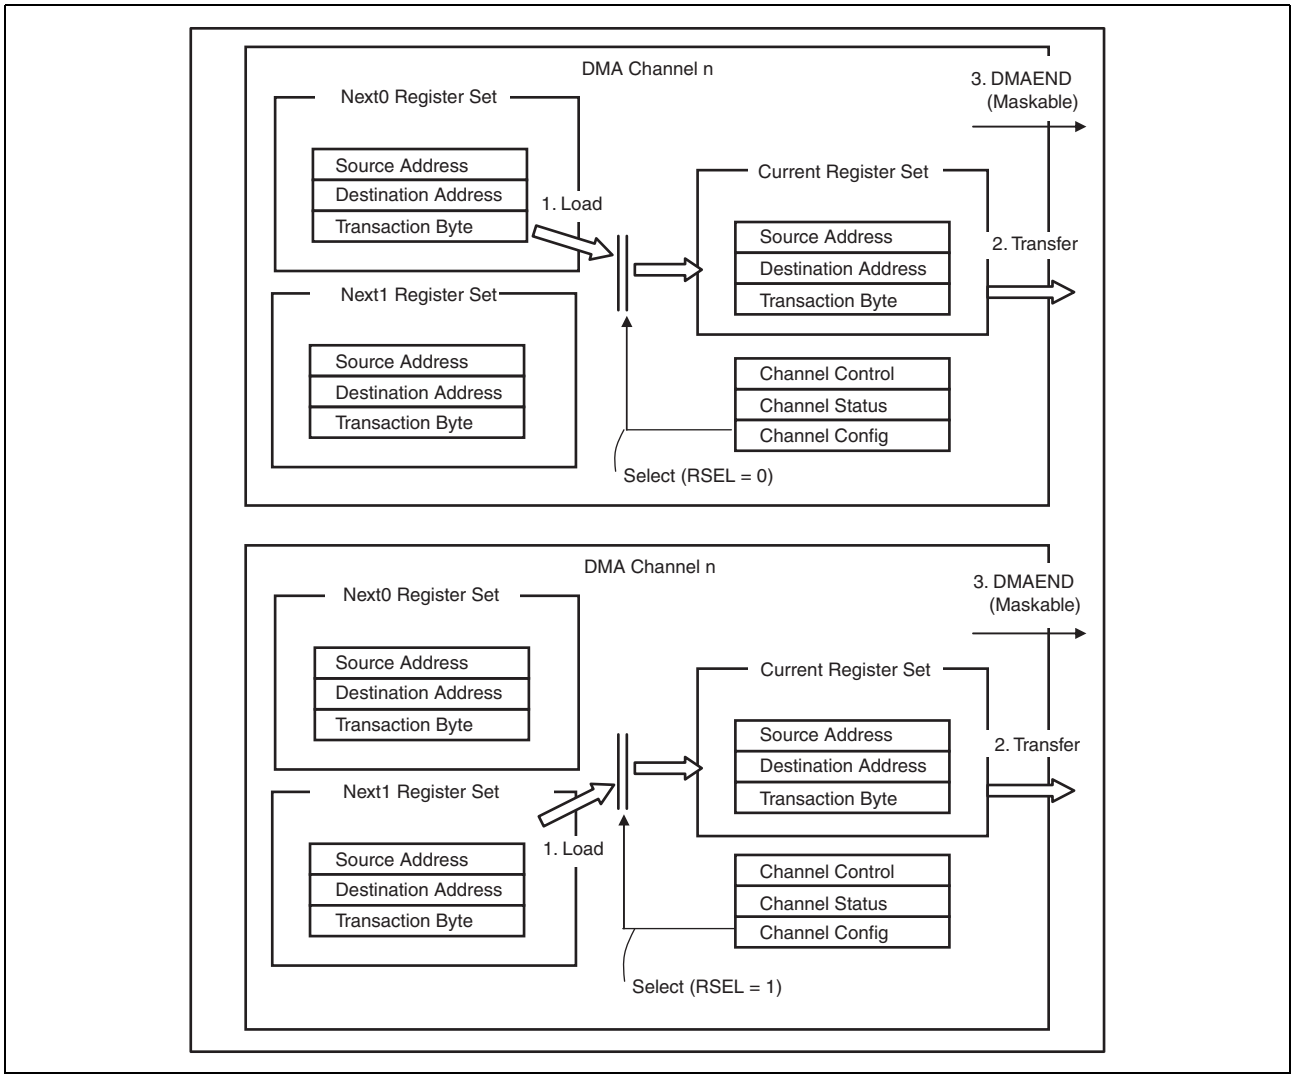

Figure 9.2 Outline of Normal Register Mode

The above figure shows how the transfer is executed when the Next0 Register Set is used (upper part of the figure) and when the Next1 Register Set is used (lower part of the figure).

(1) Operation Flow

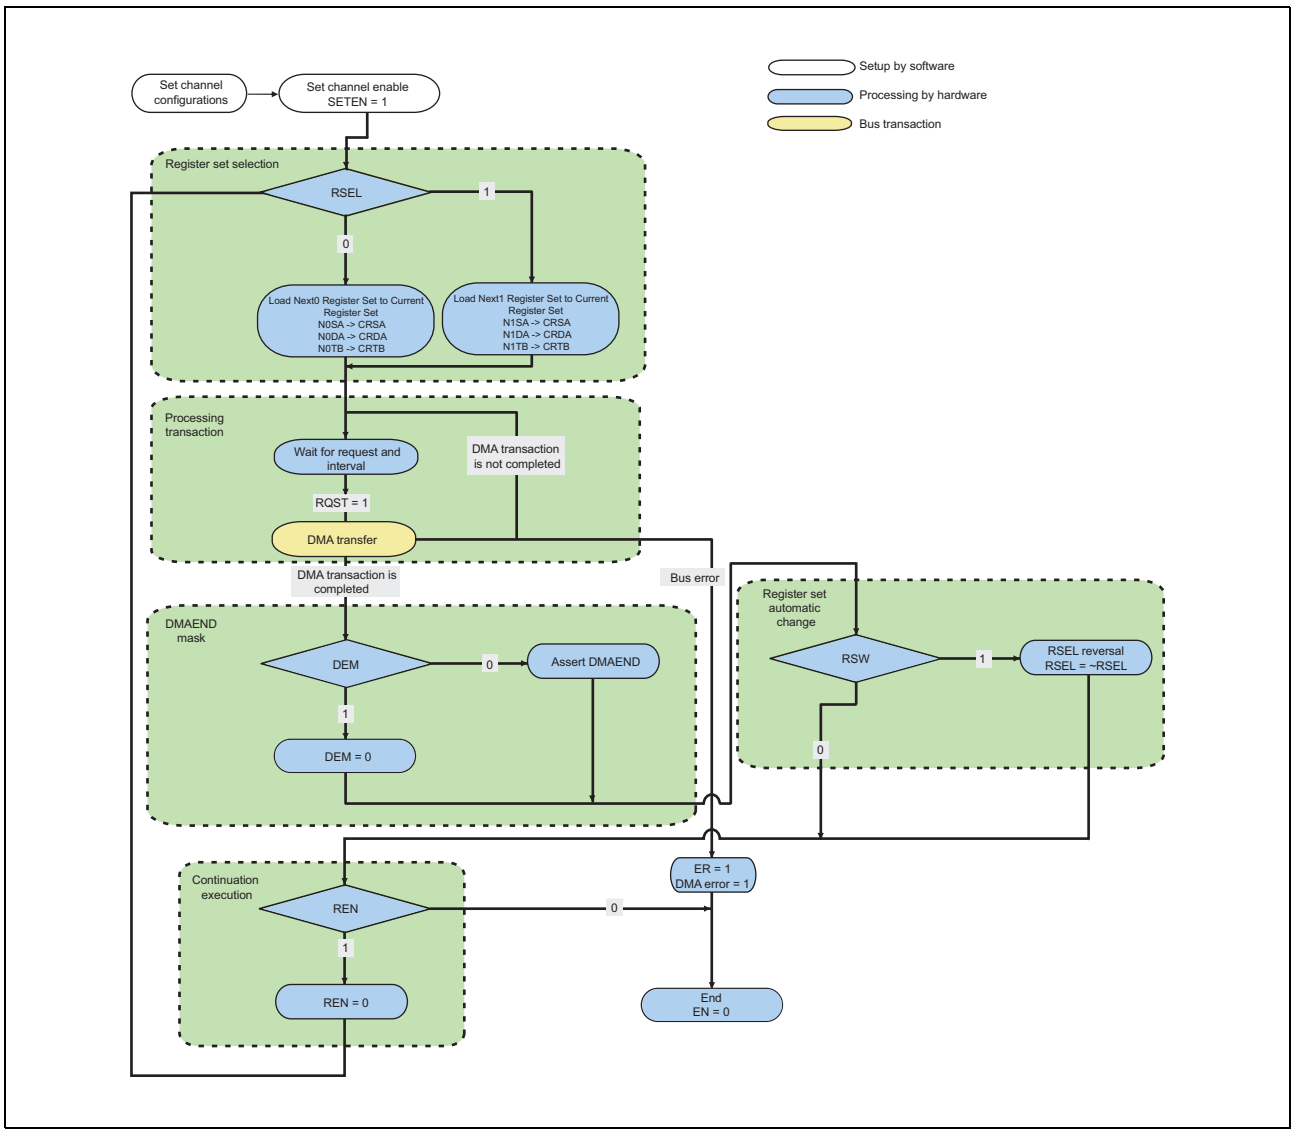

Figure 9.3 Register Mode Flow

<Explanation of the register mode flow>

1. Channel setting (set channel configuration)
   The Next0 or Next1 Register Set (destination address, source address, and total transfer byte count) is set.
   In the Channel Register Set, the DMA Register Set (REQ, DMAACK, transfer size, etc.) is set. (See section 9.7, DMA Transfer.)

2. Register set selection (register set selection)
   When 1 is set in EN, the values set in the Next Register Set selected by RSEL are loaded to the Current Register Set.

3. DMA transaction (processing transaction)
   A DMA transfer is executed according to the set values. For details of the transfer, see section 9.7, DMA Transfer.

4. DMA transfer end interrupt mask (DMAINT mask)
   The DMA transfer end interrupt is masked according to the value set in the DEM bit of CHCFG_n. When 1 is set in DEM, the DMA transfer end interrupt is not output. Also, immediately after that, DEM is automatically cleared to 0.

5. Automatic register set change (register set automatic change)
   Whether to use the other Next Register Set is determined by the value set in the RSW bit of CHCFG_n.

6. Continuation of execution (continuation execution)
   Whether to continue the execution of the DMA transfer is determined by the value set in the REN bit of CHCFG_n. When 1 is set in REN, the execution of the DMA transfer is continued. Also, immediately after that, REN is automatically cleared to 0.

(2) Register Setting

(a) Register mode setting

Select the register set to be executed.

Table 9.6 Register Mode Setting

DMS (CHCFG_n)	RSEL (CHCFG_n)	Description
0	0	Executes the Next0 Register Set.
	1	Executes the Next1 Register Set.

(b) DMA transfer end interrupt mask setting

The DMA transfer end interrupt can be masked individually for each register set.

Table 9.7 DMAINT Mask Setting

DEM (CHCFG_n)	Operation	Remark
0	When the DMA transaction is completed, a DMA transfer end interrupt is issued.	
1	Even when the DMA transaction is completed, a DMA transfer end interrupt is not issued. After the DMA transaction is completed, DEM is cleared to 0 by hardware.	

(c) Automatic register set execution setting

After DMA transfers, the DMA transaction of the selected register set is automatically executed.

Table 9.8 Automatic Register Set Execution Setting

REN (CHCFG_n)	Operation	Remark
0	When the DMA transaction of the register set selected by RSEL is completed, the EN bit is cleared and the DMA operation ends.	Set this value when you want to execute a DMA transaction once.
1	When a DMA transaction is completed, the DMAC continues to execute a DMA transfer by using the data set in the selected register set. When continuous transfers are successful, REN is cleared to 0.	Set this value when you want to continuously execute DMA transfers by using the data set in separate register sets.

(d) Automatic register set change setting

When 1 is set in REN, the DMAC can automatically change to the register set to be executed next, after a DMA transaction is completed.

Table 9.9 Automatic Register Set Change Setting

RSW (CHCFG_n)	Operation	Remark
0	If 1 is set in REN when a DMA transaction is completed, the register set is not changed.	Set this value when you want to use only one register set.
1	If 1 is set in REN when a DMA transaction is completed, the value of RSEL is automatically inverted and the other register set is selected.	Set this value when you want to change the register set.

(3) Setting Examples

(a) When only the Next0 Register Set is used

Table 9.10 Register Mode Setting Example 1

DMS (CHCFG_n)	RSEL (CHCFG_n)	DEM (CHCFG_n)	RSW (CHCFG_n)	REN (CHCFG_n)
0 (Register mode)	0 (Next0)	0 (not masked)	0 (not switched)	0 (not continuously executed)

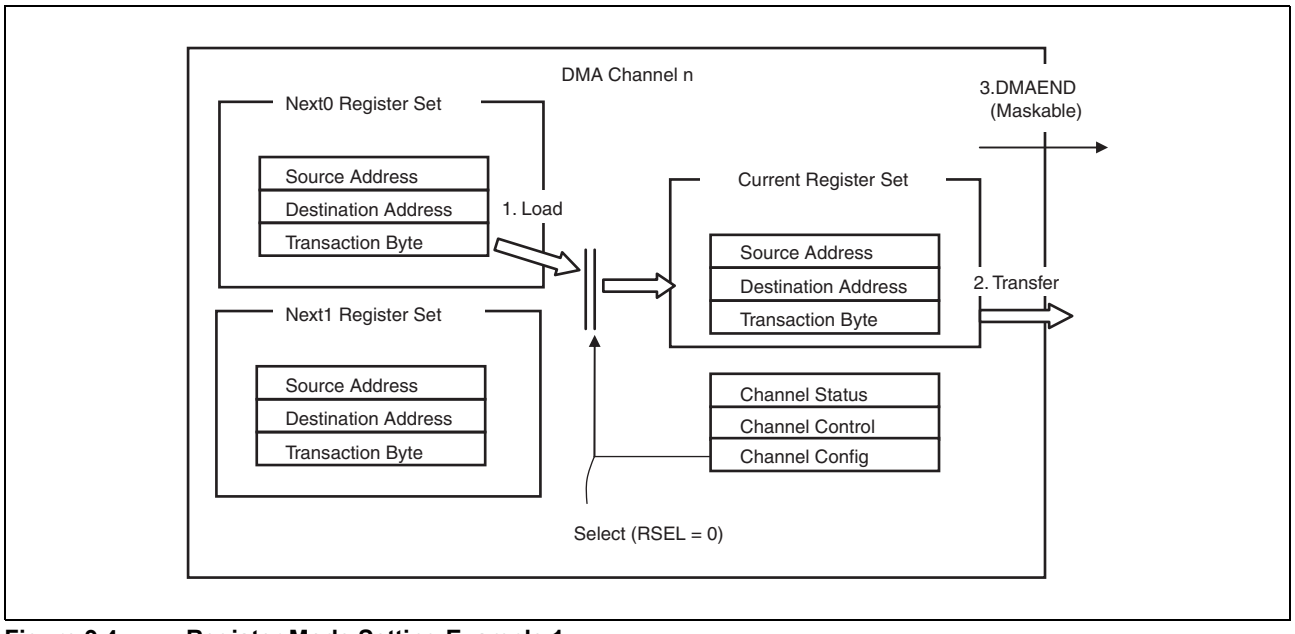

Figure 9.4 Register Mode Setting Example 1

1. 1 is set in EN (SETEN = 1), and the Next0 Register Set is loaded to the Current Register Set.
2. A DMA transaction is executed according to the values set in the Current Register Set and Channel Register Set.
3. Because 0 is set in DEM, the DMA transfer end interrupt is issued after the DMA transaction is completed.
4. Because 0 is set in REN, EN is cleared to 0 and the DMA transaction ends.

(b) When two register sets are used continuously

Table 9.11 Automatic Register Set Execution Setting

DMS (CHCFG_n)	RSEL (CHCFG_n)	DEM (CHCFG_n)	RSW (CHCFG_n)	REN (CHCFG_n)
0 (Register mode)	0 (Next0)	1 (masked)	1 (switched)	1 (continuously executed)

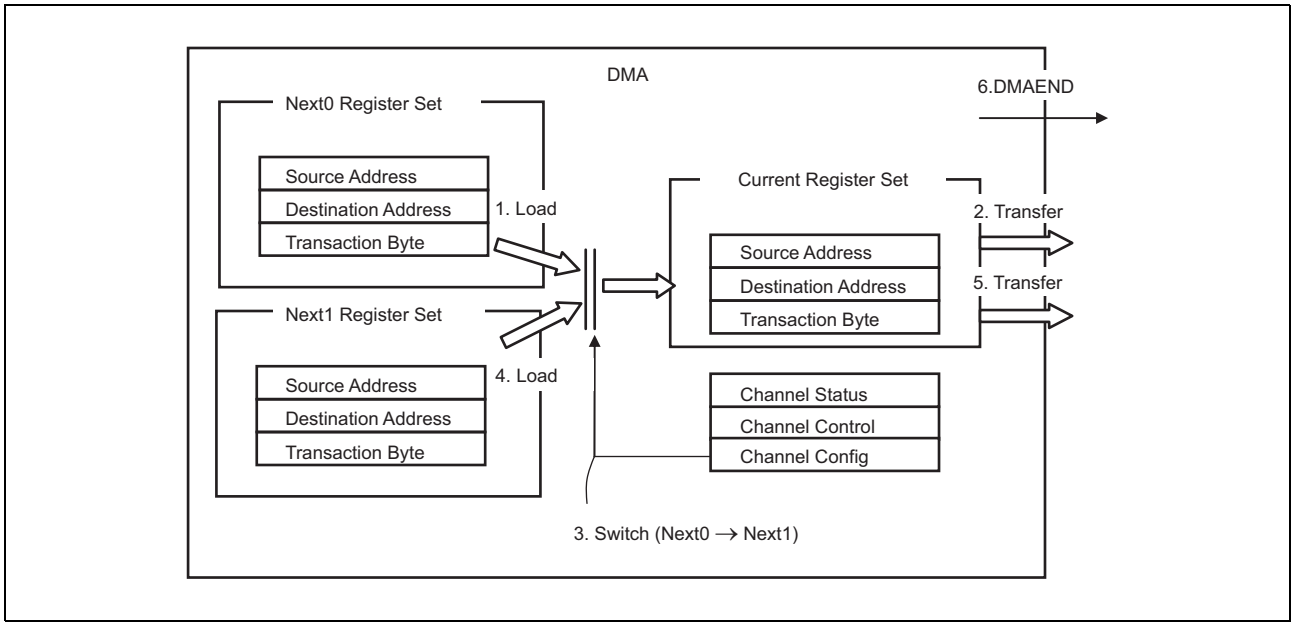

Figure 9.5 Register Mode Setting Example 2

1. 1 is set in EN (SETEN = 1), and the Next0 Register Set is loaded to the Current Register Set.
2. A DMA transaction is executed according to the values set in the Current Register Set and Channel Register Set.
3. Because 1 is set in DEM, DMA transfer end interrupt is not output after the DMA transaction is completed. Also, DEM is automatically cleared to 0.
4. Because 1 is set in REN, the execution is continued. Also, REN is automatically cleared to 0.
5. Because 1 is set in RSW, the register set to be executed next is switched (RSEL = 0 → 1).
6. The Next1 Register Set is loaded to the Current Register Set.
7. A DMA transaction is executed according to the values set in the Current Register Set and Channel Register Set.
8. Because 0 is set in DEM, the DMA transfer end interrupt is issued after the DMA transaction is completed.
9. Because 0 is set in REN, EN is cleared to 0 and the DMA transaction ends.

9.6.3 Link Mode

In link mode, a descriptor stored in external memory is loaded as set values and a DMA transaction is executed using the loaded values. The DMAC contains a Next Link address and a Current Link address for each channel, and these addresses are used to set the descriptor address to be executed next and to indicate the descriptor address of the currently executed DMA transaction, respectively.

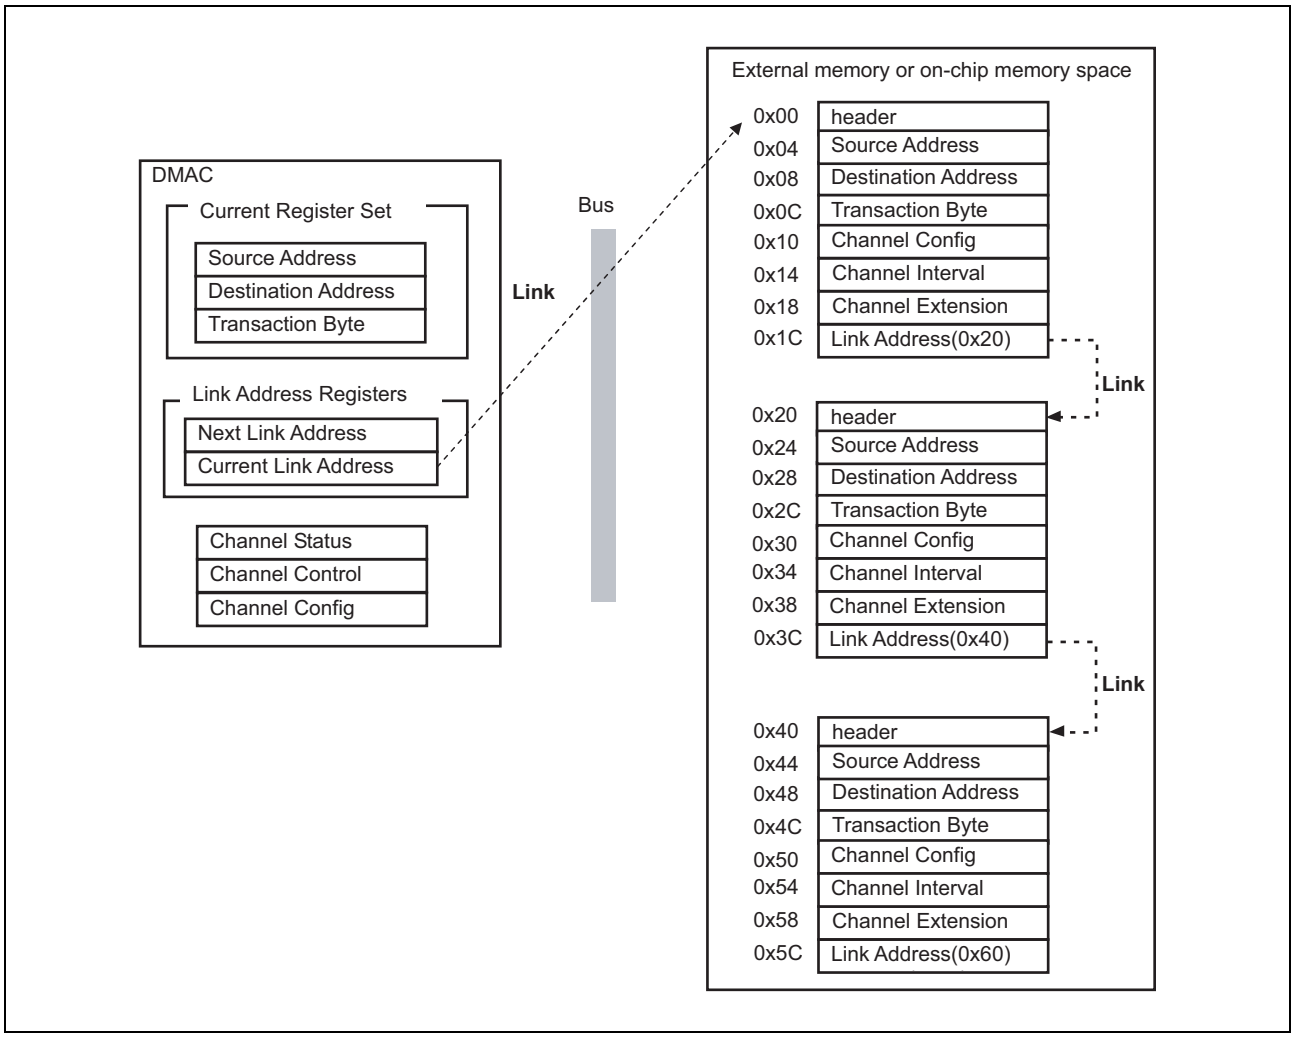

Figure 9.6 Link Mode Outline

(1) Operation Flow

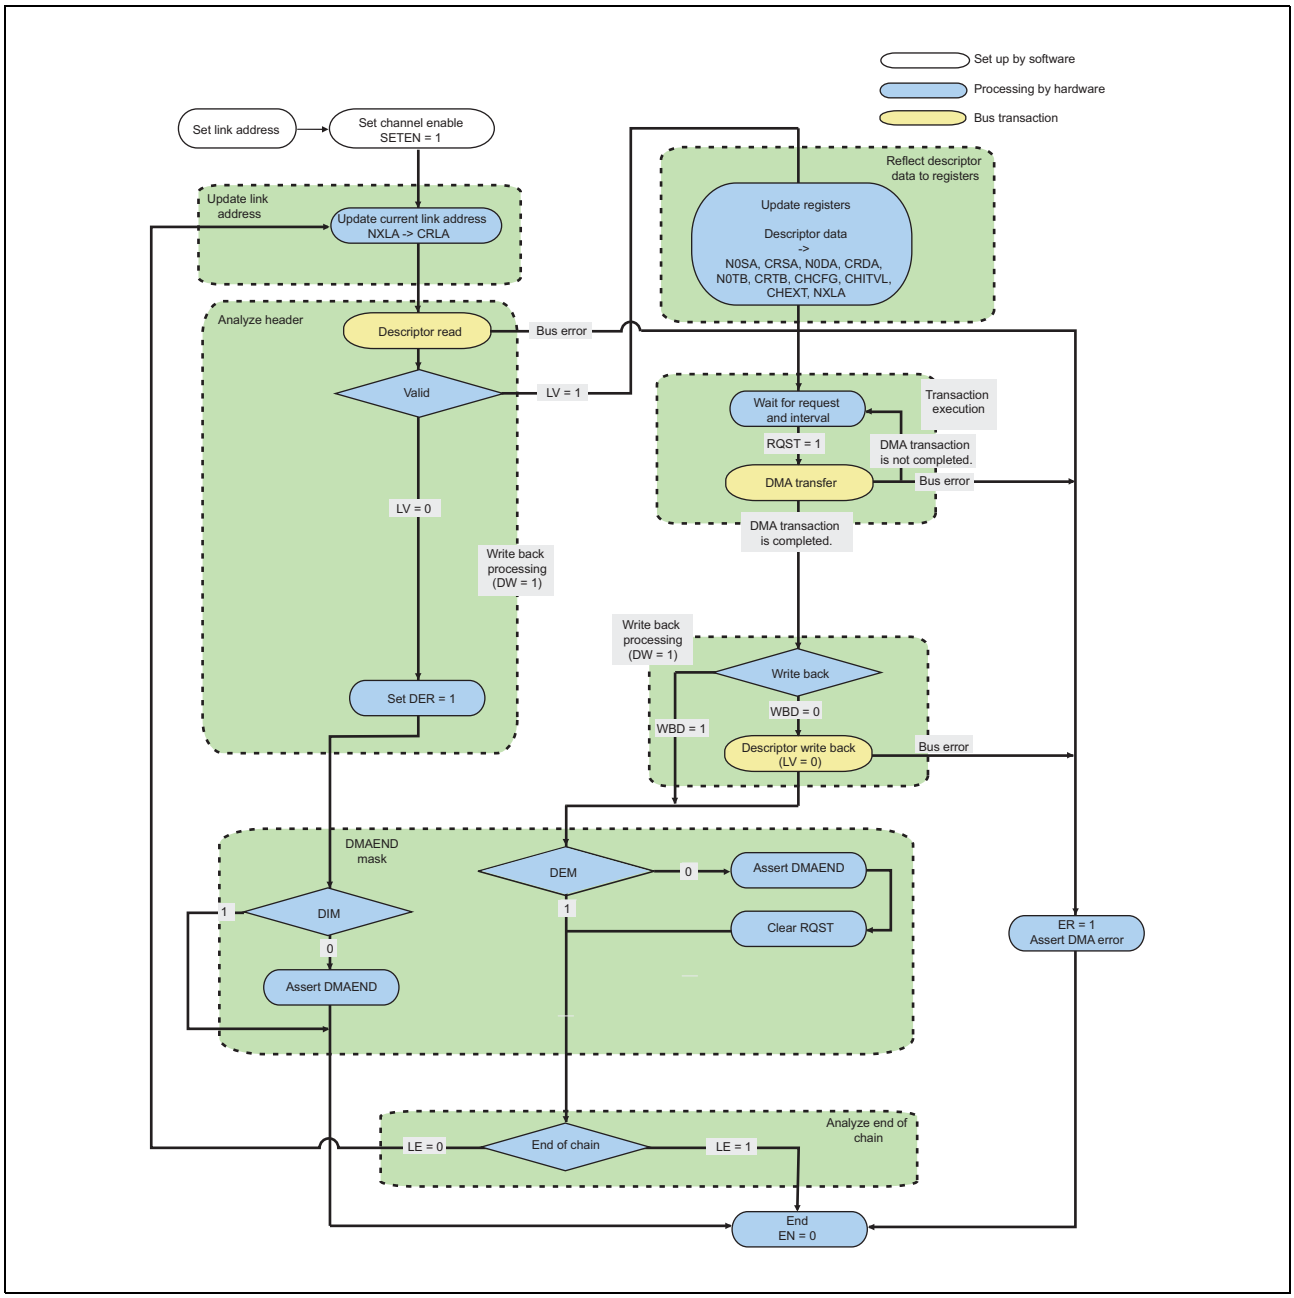

Figure 9.7 Link Mode Flow

<Explanation of the link mode flow>

1. Channel setting
   The start address of the link destination is set in NXLA_n.

2. Link address update
   When 1 is set in EN (1 is set in SETEN), the Link address set in NXLA_n is loaded to CRLA_n.

3. Descriptor load and header analysis
   The DMAC begins to load the descriptor and then analyzes the content of the header. When LV is 0, the DMAC discards the loaded descriptor and sets 1 in DER to end the operation (EN = 0). In this case, if 0 is set in DIM of the header, DMAEND is issued.

4. Descriptor setting
   The loaded descriptor is set in the Current Register Set and Channel Register Set. Also, the next link address is set in NXLA_n.

5. DMA transaction
   A DMA transaction is executed according to the set values.

6. Header writeback
   When 0 is set in WBD of the header, the DMAC writes back the header with 0 set in its LV bit.

7. DMAINT mask
   When 0 is set in the DEM bit of CHCFG_n, the DMA transfer end interrupt is issued.

8. Link end analysis
   When 1 is set in LE of the header, the operation is ended by clearing EN to 0, after the transfer using the settings of the descriptor is completed. When 0 is set in LE, the Current register is updated and the load of the next descriptor begins. TEND is issued each time a descriptor is transferred.

(2) Register Setting

(a) Link mode setting

To use the link mode, set 1 in the DMS bit of the CHCFG_n register.

Table 9.12 Link Mode Setting

DMS (CHCFG_n)	Description
1	Operates in link mode. This bit cannot be changed using a descriptor.

(b) Link address setting

There are two registers that indicate a link address: Next Link address register and Current Link address register.
To start the link mode, set a link address in the Next Link address register.
The Next Link address indicates the next link address after a descriptor is loaded. The Current Link address indicates the currently executed link address.

Table 9.13 Link Address Register Set

Register	Description
Next Link Address Register (NXLA_n)	Sets and indicates the next link address. Before starting the link mode, set a link address in this register.
Current Link Address Register (CRLA_n)	Indicates the currently executed link address. This register is read-only.

<Caution> In link mode, the settings can be changed by reading a descriptor. It is not possible, however, to synchronize the change of the settings with a peripheral module request or external request. Therefore, when using a peripheral module request or external request, set AM, LVL, HIEN, LOEN, and SEL of the CHCFG_n register before setting Enable and do not change any of these bits in the descriptor.

(3) Descriptor Setting

In a link address, prepare a descriptor with data arranged in the order shown below.
The DMAC reads the descriptor in burst mode.

(a) Descriptor data arrangement

Table 9.14 Descriptor Data Arrangement

Address	Data	Remark
Link address + 00H	header	
Link address + 04H	Source Address	
Link address + 08H	Destination Address	
Link address + 0CH	Transaction Byte	
Link address + 10H	Config	The register mode cannot be set.
Link address + 14H	Interval	
Link address + 18H	Extension	
Link address + 1CH	Next Link Address	

Remark: As a link address, set an address aligned along the 32-bit boundary.

(b) header

The header indicates the status of the descriptor, as shown below.
The DMAC reads this area when a DMA transfer is started in link mode. Also, after a DMA transaction is completed, the DMAC writes back the transfer status to the area.

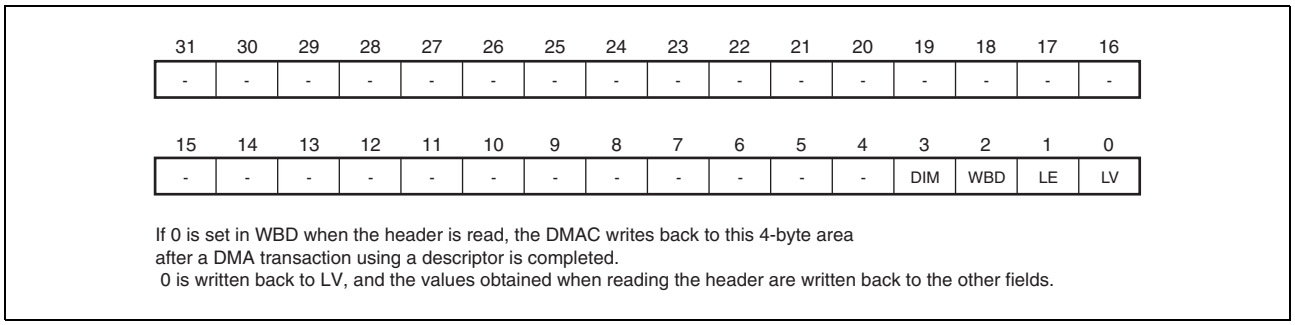

Figure 9.8 header Area

Table 9.15 Header Area

Bit Position	Bit Name	Meaning
31 to 4	—	—
3	DIM	Descriptor Interrupt Mask Sets whether to mask the DMA transfer end interrupt if 0 is set in LV when the header is loaded. 0: Issues a DMA transfer end interrupt. 1: Does not issue a DMA transfer end interrupt.
2	WBD	Write Back Disable Sets whether to mask LV bit writeback. When 1 is set in this bit, the DMAC does not perform writeback. 0: Writes the LV bit back to 0. 1: Does not write back the LV bit.
1	LE	Link End Indicates whether the link ends with the DMA transaction of this descriptor. Set 1 in this bit to indicate the end of the link. 0: The link continues. 1: The link ends.
0	LV	Link Valid Indicates whether this descriptor is valid. If 0 is set in WBD, the DMAC writes 0 in this bit after the DMA transaction written in the descriptor is executed. When setting the header, set 1 in this bit. 0: Descriptor invalid 1: Descriptor valid

(c) Descriptor data other than the header

The data items of the descriptor other than the header are the same as defined in the internal register specifications (note that the DMS bit of the CHCFG_n register cannot be changed using the descriptor). For information about the internal register specifications, see section 9.4, Register Descriptions.
For descriptor setting examples, see section 9.8, DMA Setting Examples.

(d) CACHE settings for descriptor access

The CACHE settings for descriptor access can be set in LWCA and LDCA of the DMA control register (DCTRL_0_7, DCTRL_8_15). Make these settings as appropriate for the access destination in which the descriptor is prepared.

(e) Descriptor area and DMA transfer area

The following figure outlines the descriptor area and DMA transfer area that are accessed by the DMAC.

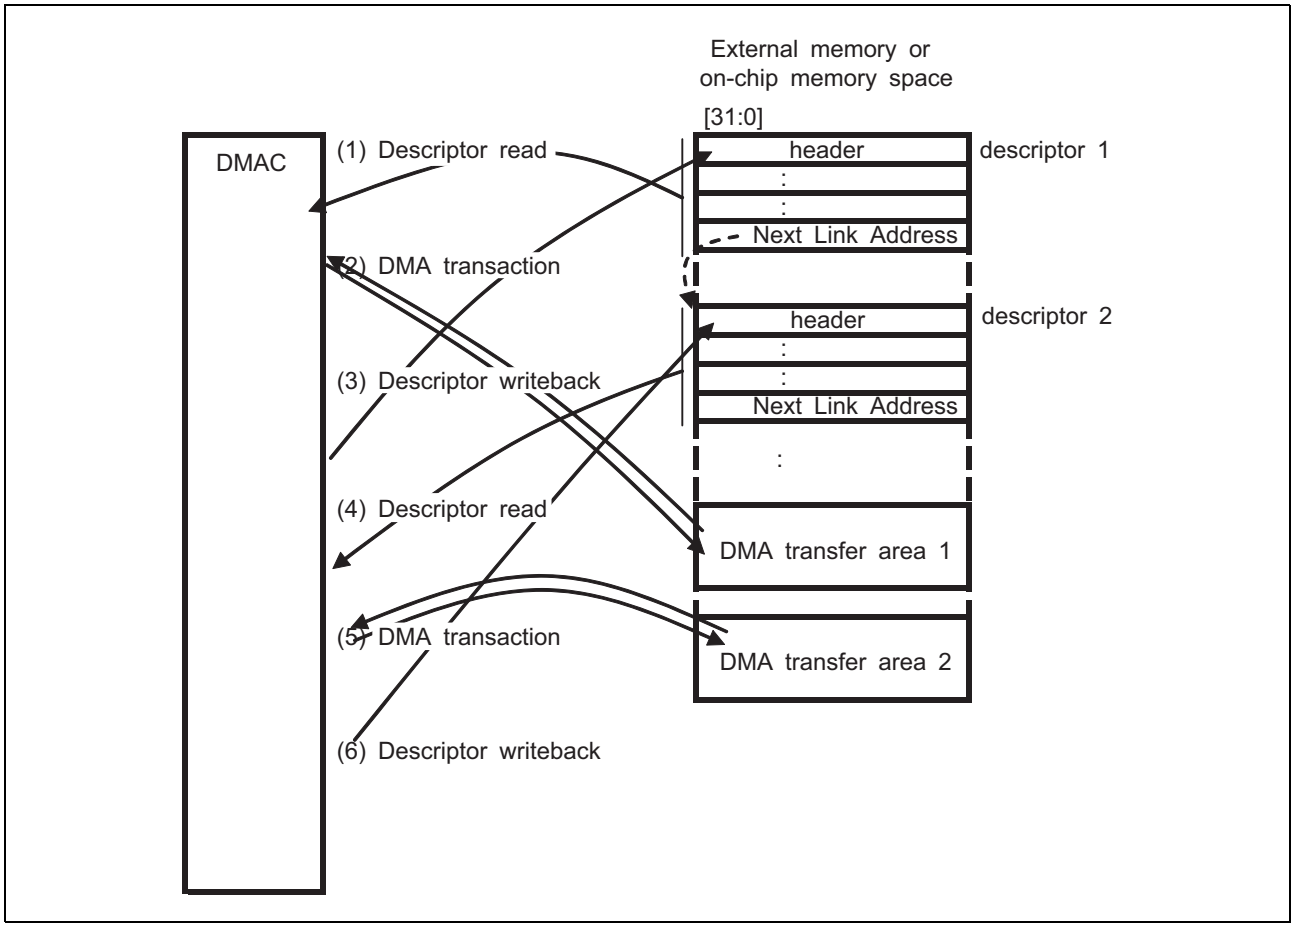

Figure 9.9 Outline of the Descriptor Area and DMA Transfer Area

1. Descriptor read
   The values set in the internal Next Link Address register are loaded to the Current Link Address register, and a descriptor is read from the external memory space (descriptor1) pointed to by the Current Link Address register.
2. DMA transfer
   When 1 is set in the LV bit of the header in the descriptor, a DMA transfer is executed according to the descriptor data.
3. Descriptor writeback
   When 0 is set in the WBD bit of the header after the DMA transfer of the set number of bytes is completed, the DMAC writes back data in word size to the header of descriptor1, with 0 set in LV and the other bits containing the values read in <1>.
4. Descriptor read
   When 0 is set in the LE bit of the header in the last read descriptor (<1>), the next descriptor is read from the address (descriptor2) indicated by Next Link Address in the descriptor.
5. DMA transfer
   When 1 is set in the LV bit of the header in the descriptor, a DMA transfer is executed according to the descriptor data.
6. Descriptor writeback
   When 0 is set in the WBD bit of the header after the DMA transfer of the set number of bytes is completed, the DMAC writes back data in word size to the header of descriptor2, with 0 set in LV and the other bits containing the values read in <4>.

4 through 6 are repeated.
When the header contains 1 in LE and 0 in WBD, the DMAC executes a DMA transfer using the settings of that descriptor, writes back data with 0 set in the LV bit of the header and ends the operation.
When the header contains 1 in both LE and WBD, the DMAC executes a DMA transfer using the settings of that descriptor and ends the operation (without writing back).
When the header contains 0 in LV, the DMAC ends the operation (without executing a DMA transfer).

(4) Descriptor Configuration Examples

In link mode, a descriptor can be configured as shown below.

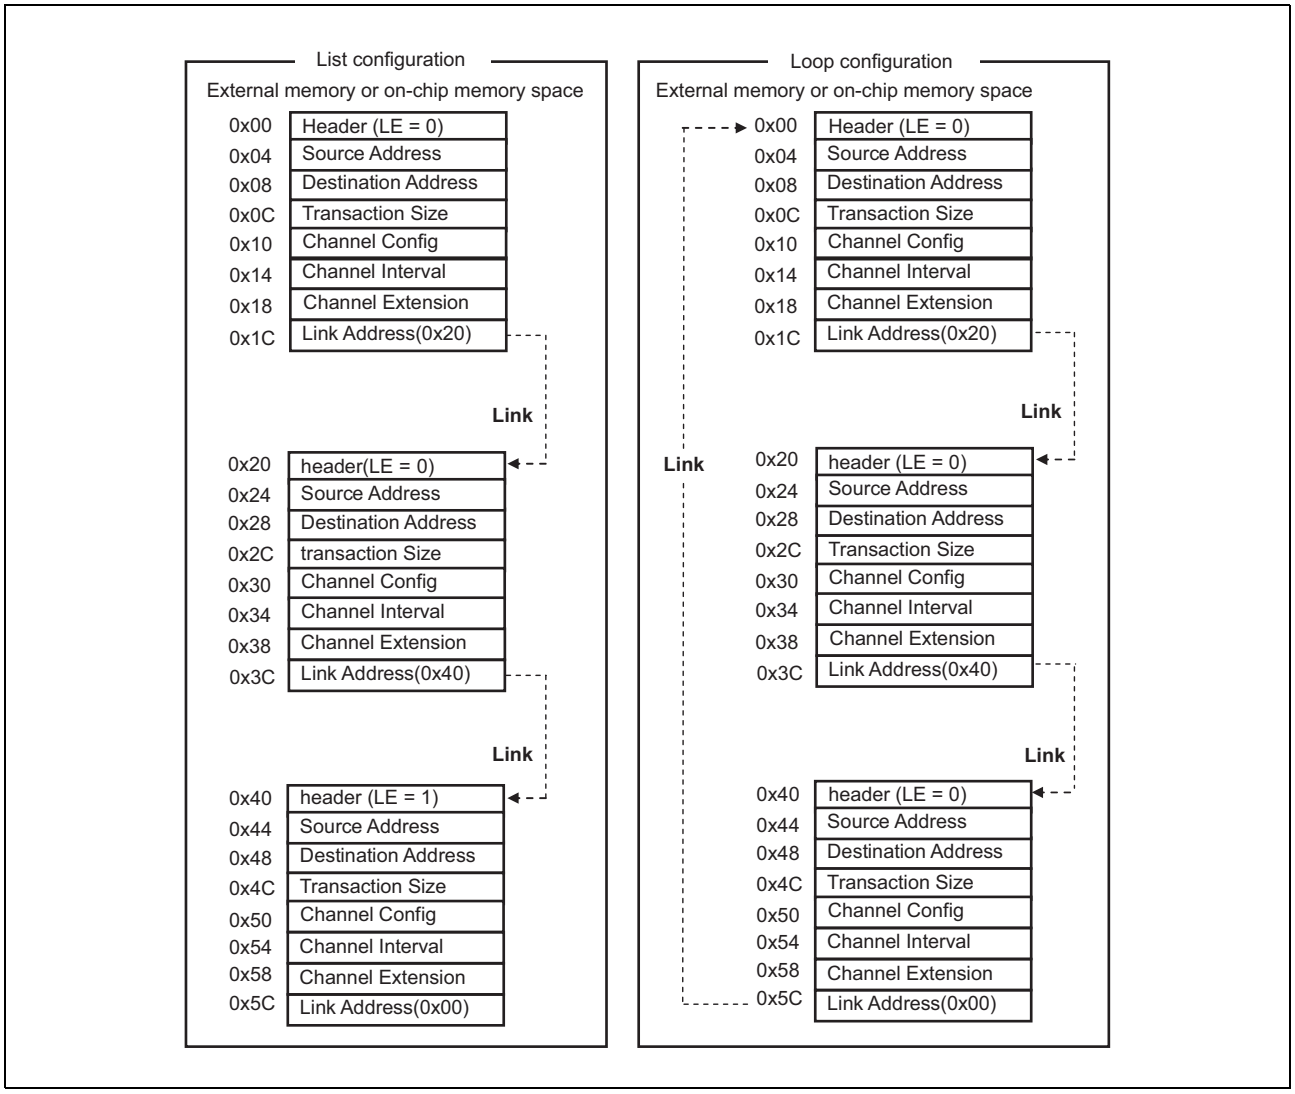

Figure 9.10 Descriptor Configuration Examples

- List configuration
  The link is ended by setting 1 in the LE bit of the header in the last descriptor.

- Loop configuration
  A descriptor can be created with a loop configuration, by setting the address of the top descriptor in the link address of the last descriptor. To end the loop, change the value of the LE bit of the header to 1 before the DMAC reads the descriptor, or follow the transfer suspension procedure.

9.7 DMA Transfer

The basic operation of DMA transfer is described here.

9.7.1 Transfer Mode

Two transfer modes are supported: single transfer mode and block transfer mode.
To select a transfer mode, set the TM bit of CHCFG_n for each channel.

Table 9.16 Basic Transfer Setting

Transfer Mode	TM (CHCFG_n)	Function
Single transfer	0	A single DMA transfer is executed in response to a DMAREQ.
Block transfer	1	In response to a DMAREQ, the DMAC continues to execute the transfer until the DMA transaction is completed.

(1) Single Transfer Mode

When a DMA transfer request is received, a DMA transfer is executed once in the direction indicated by REQD (source or destination). A DMA transfer is executed once each time a transfer request is received, and this operation continues until the number of bytes loaded to CRTB_n is reached (arbitration between channels is accomplished for each DMA transfer).

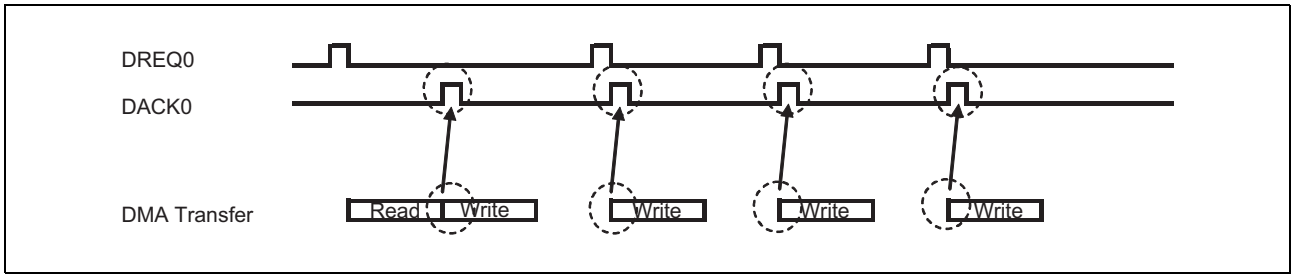

Figure 9.11 Single Transfer Mode (REQD = 1, SDS > DDS)

(2) Block Transfer Mode

Once a DMA transfer request is received, the DMAC continues to execute the transfer until data equivalent to the number of bytes loaded to the DMA transfer byte register (CRTB_n register) is transferred (the DMA transaction is completed) (arbitration between channels is accomplished for each DMA transfer).

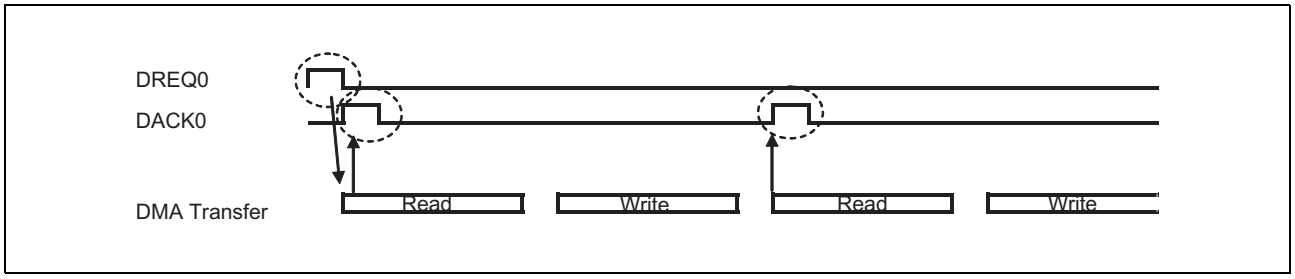

Figure 9.12 Block Transfer Mode (REQD = 0, SDS < DDS)

9.7.2 Priority Control for DMA Channels

Within channels 0 to 7 and 8 to 15, two priority control modes are supported: fixed priority mode and round robin mode. Only round robin mode is supported for priority control between the group of channels 0 to 7 and the group of channels 8 to 15. To select a priority control mode, use the PR bit of the DMA control register (DCTRL register). The fixed priority mode is selected when 0 is set in the PR bit, and the round robin mode is selected when 1 is set.
Read priority and write priority are controlled independently.
The DMAC issues transfer requests to different channels concurrently without waiting for the completion of any particular transfer and processes responses in the order it receives them. Therefore, the order in which the channels start transactions is not necessarily consistent with the order in which the transactions end.

Table 9.17 Priority Control Setting

Mode	PR (DCTRL)	Function	Purpose
Fixed priority	0	Requests are controlled based on the fixed order of priority for channels 0 to 7 and 8 to 15 (High: CH0 (CH8) > CH1 (CH9) > CH2 (CH10) > CH3 (CH11) > CH4 (CH12) > CH5 (CH13) > CH6 (CH14) > CH7 (CH15): Low).	Use this mode when the channels have a specific order of priority.
Round robin	1	Requests are controlled in a round robin fashion.	Use this mode when you want requests evenly executed.

(1) Fixed Priority Mode

In fixed priority mode, the channels have a fixed order of priority in channels 0 to 7 and 8 to 15. Round robin mode is used to determine the priority between the group of channels 0 to 7 and the group of channels 8 to 15.
Immediately after a reset, the order of priority is as follows.
High CH0 > CH8 > CH1 > CH9 > CH2 > CH10 > CH3 > CH11 > CH4 > CH12 > CH5 > CH13 > CH6 > CH14 > CH7 > CH15 Low
If there is a transfer request from DMA channel 0 in this state, a transfer is executed on DMA channel 0. After the transfer is completed, the order of priority is as follows.
High CH8 > CH0 > CH9 > CH1 > CH10 > CH2 > CH11 > CH3 > CH12 > CH4 > CH13 > CH5 > CH14 > CH6 > CH15 > CH7 Low
If a DMA transfer request occurs on multiple channels simultaneously, the DMA transfer request of the channel having the smallest channel number is given priority. The following figure shows an example where a DMA transfer request occurs on a channel having a higher priority while a DMA transfer is being executed in fixed priority mode.

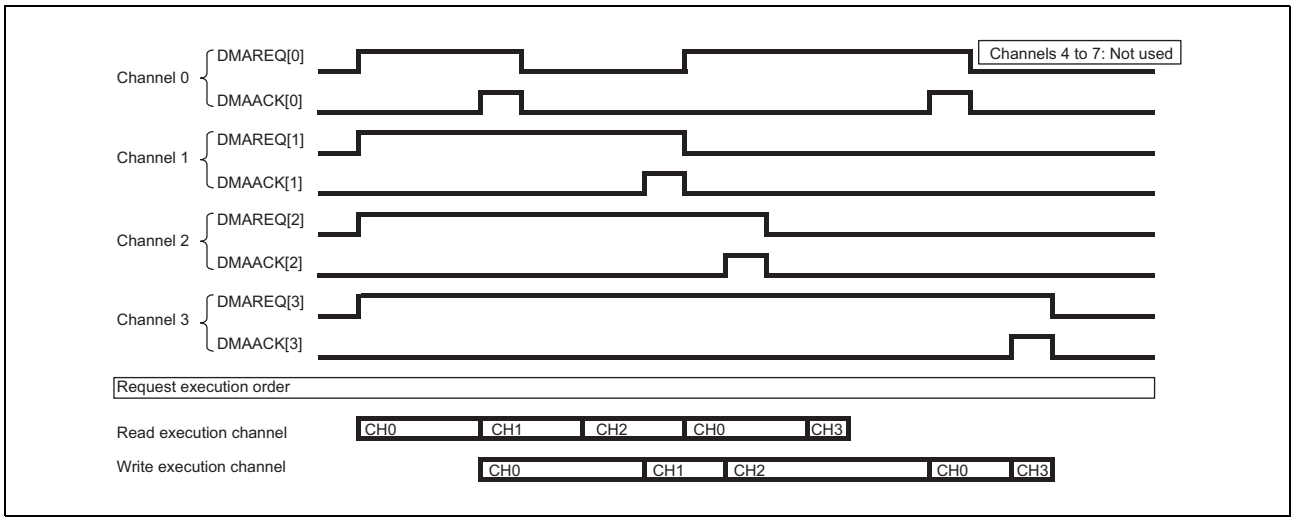

Figure 9.13 Fixed Priority Mode (Number of Channels = 4, REQD = 1)

(2) Round Robin Mode

In round robin mode, each time a transfer request is received from a channel in the group of channels 0 to 7 and the group of channels 8 to 15, the order of priority is changed in such a way that the channel that executed a transfer last has the lowest priority.

Round robin mode is used to determine the priority between the group of channels 0 to 7 and the group of channels 8 to 15.

Immediately after a reset, the order of priority is the same as that of the fixed priority mode, which is as follows.

High CH0 > CH8 > CH1 > CH9 > CH2 > CH10 > CH3 > CH11 > CH4 > CH12 > CH5 > CH13 > CH6 > CH14 > CH7 > CH15 Low

If a transfer request is received from DMA channel 2 in this state, a transfer is executed on DMA channel 2. After the transfer is completed, the order of priority is as follows.

High CH8 > CH3 > CH9 > CH4 > CH10 > CH5 > CH11 > CH6 > CH12 > CH7 > CH13 > CH0 > CH14 > CH1 > CH15 > CH2 Low

The following figure shows an example where DMA transfers are executed in round robin mode.

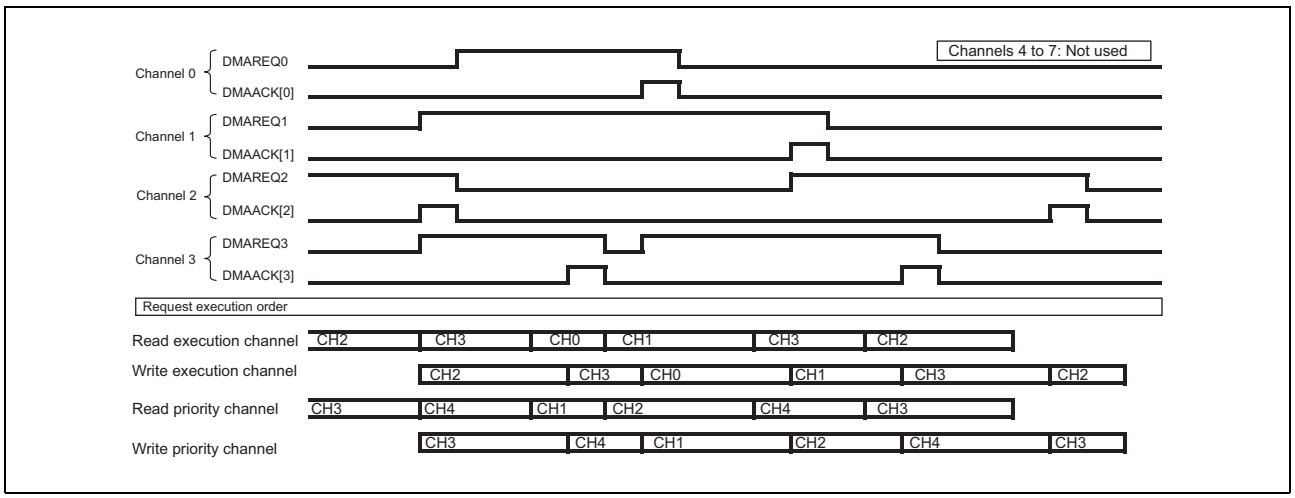

Figure 9.14 Round Robin Mode (Number of Channels = 4, REQD = 0)

The channel whose channel number is the number of the currently transferring channel + 1 gets to execute a DMA transfer next. If there is no transfer request from this channel, the channel whose channel number is the number of this channel + 1 gets to execute a DMA transfer.

9.7.3 Number of States of an External Bus Cycle

When this module is the bus master, the number of states of an external bus cycle is controlled by the bus state controller as when the CPU is the bus master. For details, refer to section 8, Bus State Controller.

9.7.4 DMA Transfer Request

Edge detection or level detection can be selected using the LVL bit of the CHCFG_n register.
The HIEN and LOEN bits of the CHCFG_n register are used to select either the rising edge or falling edge in the case of edge detection or either the high level or low level in the case of level detection.
When the transfer request is by an on-chip peripheral module, set the CHCFG_n register according to Table 9.4, On-Chip Peripheral Module Requests.
When the transfer request is by the external pin (DREQ0), set the detection conditions (rising/falling edge and high/low level) according to Table 9.18, Setting for Detection of External Pin Request.

Table 9.18 Setting for Detection of External Pin Request

Mode	LVL (CHCFG_n)	HIEN (CHCFG_n)	LOEN (CHCFG_n)	Function
Edge detection	0	0	0	Specify this value when you use auto request triggers.
			1	Detects external pin request (DREQ0) at its falling edge.
		1	0	Detects external pin request (DREQ0) at its rising edge.
			1	Setting prohibited
Level detection	1	0	0	Setting prohibited
			1	Detects external pin request (DREQ0) in Low level mode.
		1	0	Detects external pin request (DREQ0) in High level mode.
			1	Setting prohibited

(1) Edge Detection

Setting 0 in the LVL bit of the CHCFG_n register enables edge detection.
When 1 is set in the HIEN bit of the CHCFG_n register, rising edge detection is enabled. When 1 is set in the LOEN bit, falling edge detection is enabled.
Wait for DACK0 to be detected, before issuing the next DREQ0 request.

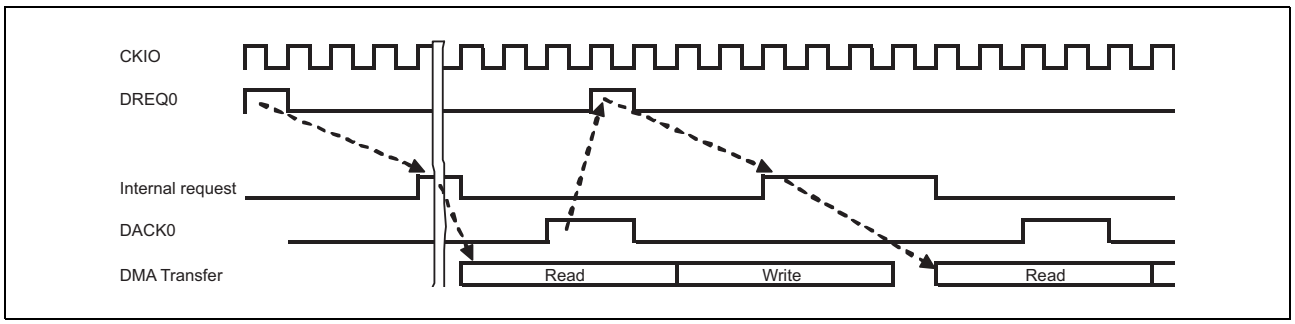

Figure 9.15 Edge Detection Timing (HIEN = 1, REQD = 0)

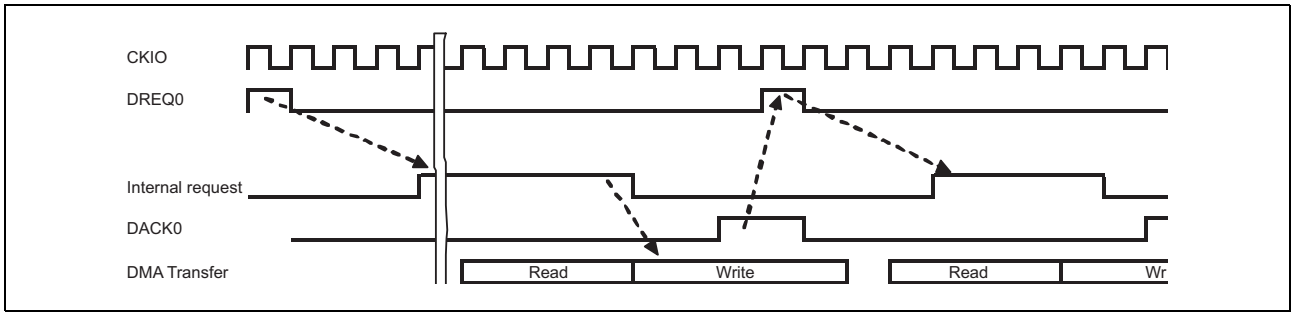

Figure 9.16 Edge Detection Timing (HIEN = 1, REQD = 1)

(2) Level Detection

Setting 1 in the LVL bit of the CHCFG_n register enables level detection.
DREQ0 is regarded as valid when it remains active for two consecutive clock cycles or more (depending on the HIEN and LOEN settings).
When the level mode is selected for DACK0, it remains at the High level until DREQ0 is deasserted.
When the next DMA transfer request is to be issued, DACK0 needs to be deasserted before that DREQ0 can be asserted.

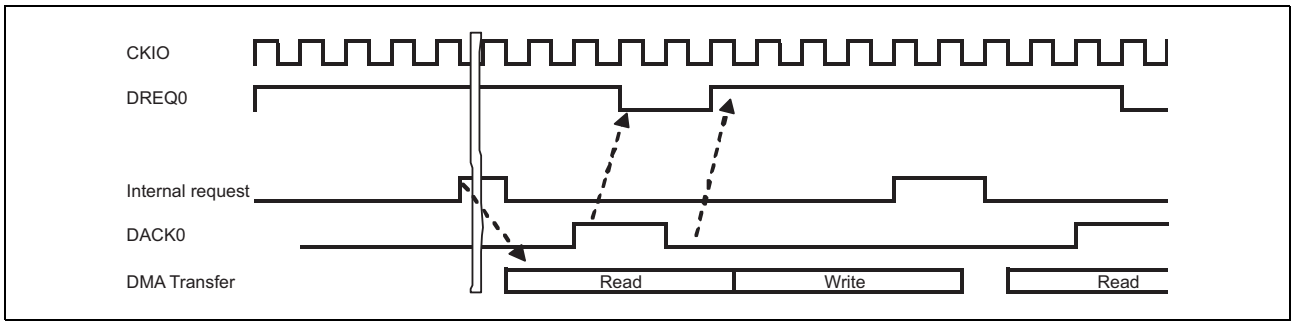

Figure 9.17 Level Detection Timing (HIEN = 1, REQD = 0, AM[2:0] = 001)

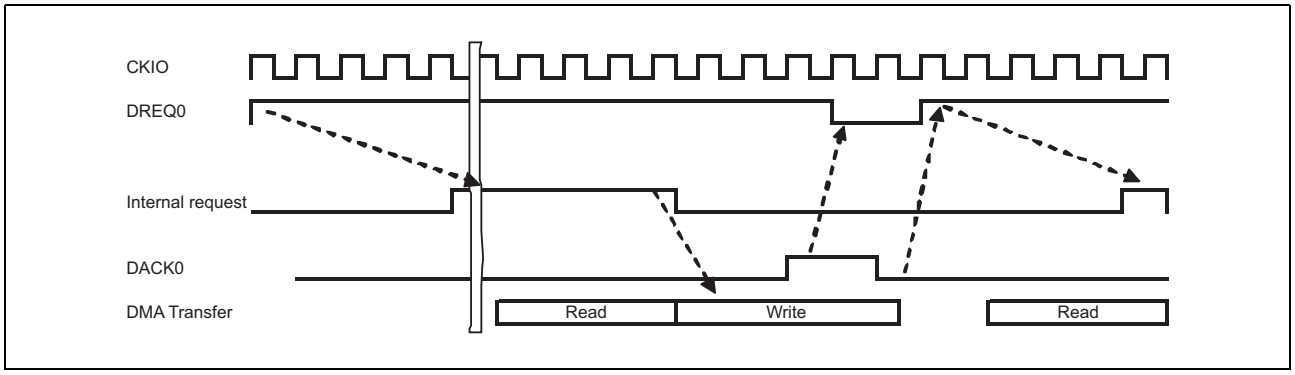

Figure 9.18 Level Detection Timing (HIEN = 1, REQD = 1, AM[2:0] = 001)

9.7.5 DMA Acknowledge Output Function

DACK0 is an acknowledge signal that is sent to DREQ0. Level output and bus cycle output settings are supported as the DACK0 output mode. DACK0 is asserted at the same time as $\overline{CS}$ assertion except for the MPX-IO interface. For details, refer to section 8, Bus State Controller.

(1) DMA Acknowledge Signal Output Timing Setting

Upon receiving a DMA transfer request, the DACK0 pin becomes active (High level output). By using the REQD and AM[2:0] bits of the CHCFG_n register, the DACK0 output timing can be set as shown below.

Table 9.19 DACK0 Output Timing Setting

Mode	AM[2] (CHCFG_n)	AM[1:0] (CHCFG_n)	REQD (CHCFG_n)	Purpose
Pulse	0	00	0	Setting prohibited
			1	
Level	0	01	0 (Active during read)	DACK0 is output as a level. DACK0 remains asserted until DREQ0 is deasserted.
			1 (Active during write)	
Bus cycle	0	10 11	0 (Active during read)	DACK0 is output for the duration of a bus cycle. Use this mode when you want to keep DACK0 asserted until the end of the bus cycle.
			1 (Active during write)	
Mask	1	—	—	Make this setting when using auto request trigger.

(2) Level Output

Setting 001 in the AM bits of the CHCFG_n register enables level output. DACK0 remains asserted until DREQ0 is deasserted.

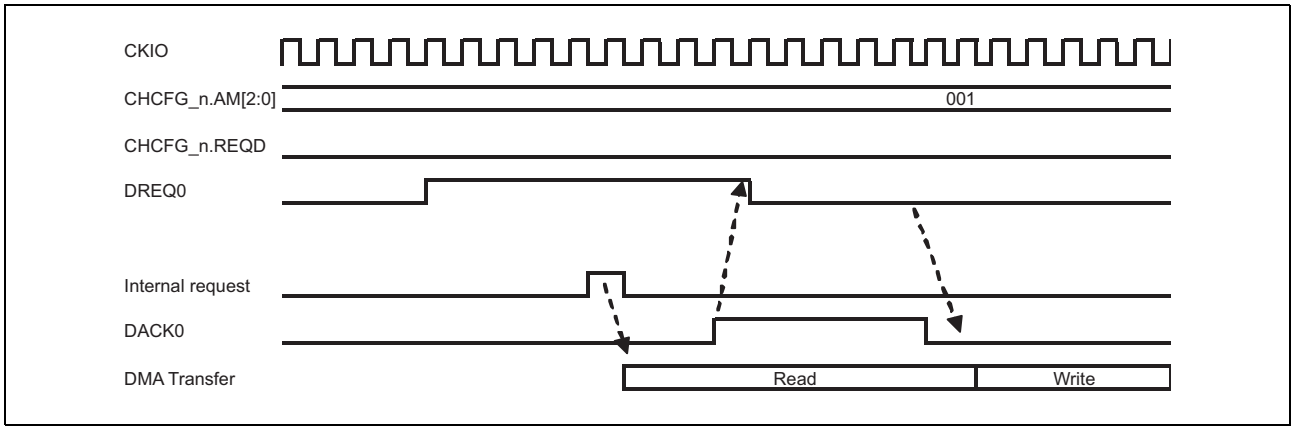

Figure 9.19 DACK0 Output Timing (AM[2:0] = 001, REQD = 0)

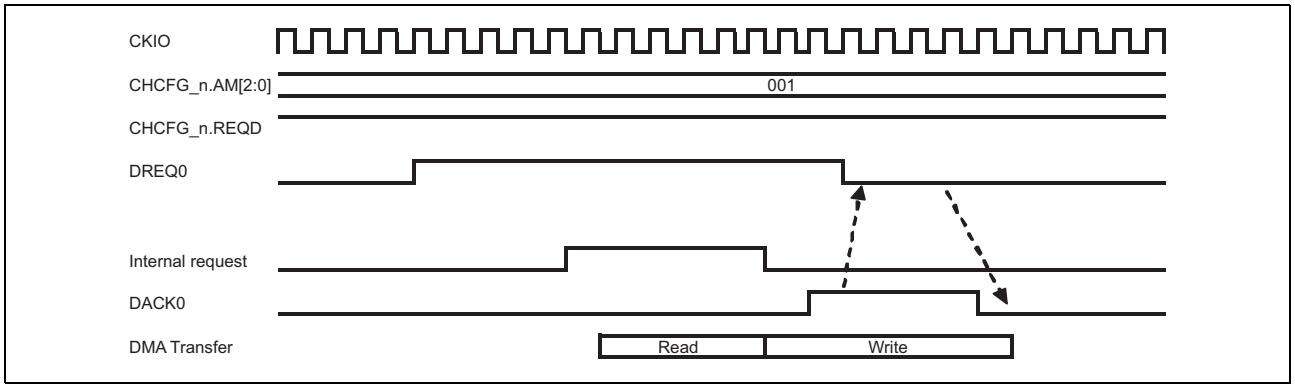

Figure 9.20 DACK0 Output Timing (AM[2:0] = 001, REQD = 1)

(3) Bus Cycle Output

Setting 010 in the AM bits of the CHCTRL_n register enables bus cycle output. DACK0 remains active for the duration of a bus cycle.

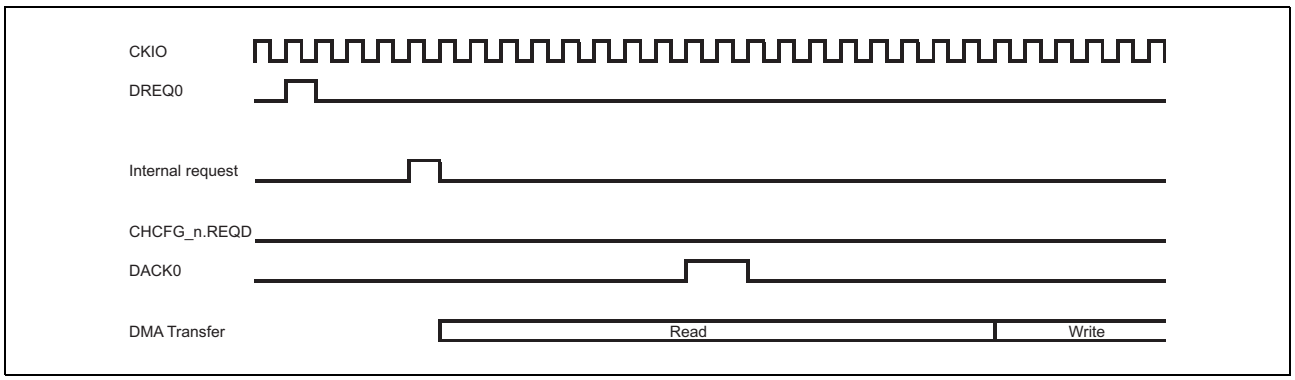

Figure 9.21 Bus Cycle Output Timing (REQD = 0)

- In the read active mode (REQD = 0), DACK0 remains active from the time when a read request is output on the bus until one cycle after the final read data.
- When level detection is selected for DREQ0, DREQ0 remains disabled until the cycle following the end of the bus cycle.

The following signals trigger the rise and fall of DACK0:

Rise: Transfer start (MARVALID = 1)

Fall: Transfer end (MRLAST & MRREADY = 1)

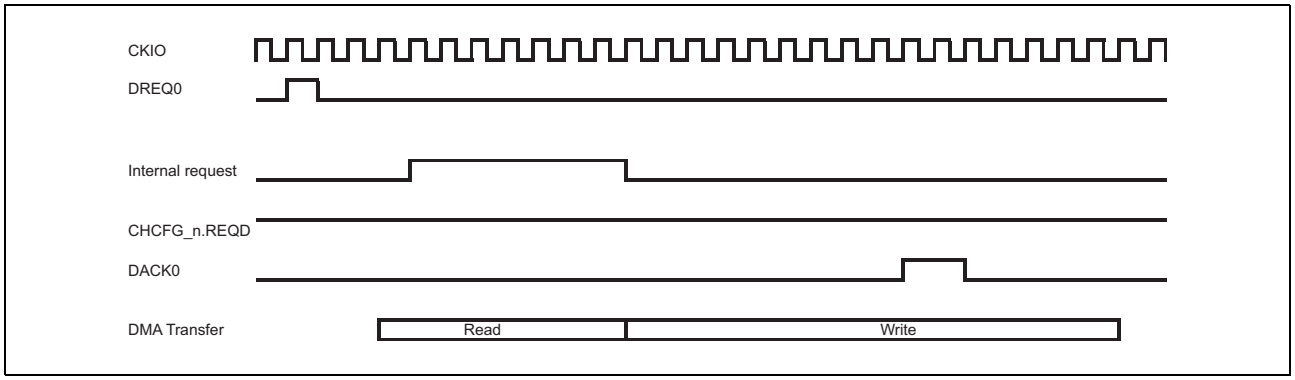

Figure 9.22 Bus Cycle Output Timing (REQD = 1)

- In the write active mode (REQD = 1), DACK0 remains active from the time when a write request is output until one cycle after the response to the final data is returned.
- When level detection is selected for DREQ0, DREQ0 remains disabled until the cycle following the end of the bus cycle.

The following signals trigger the rise and fall of DACK0:
Rise: Transfer start (MAWVALID = 1)
Fall: Transfer end (MBVALID & MBREADY = 1)

9.7.6 DMA Transfer End Output Function

TEND0 is a transaction completion signal that is sent to the source of a DMA transfer request. TEND0 is asserted as the same time as DACK0 for the last transfer transaction. Figure 9.23 shows the TEND0 output timing.

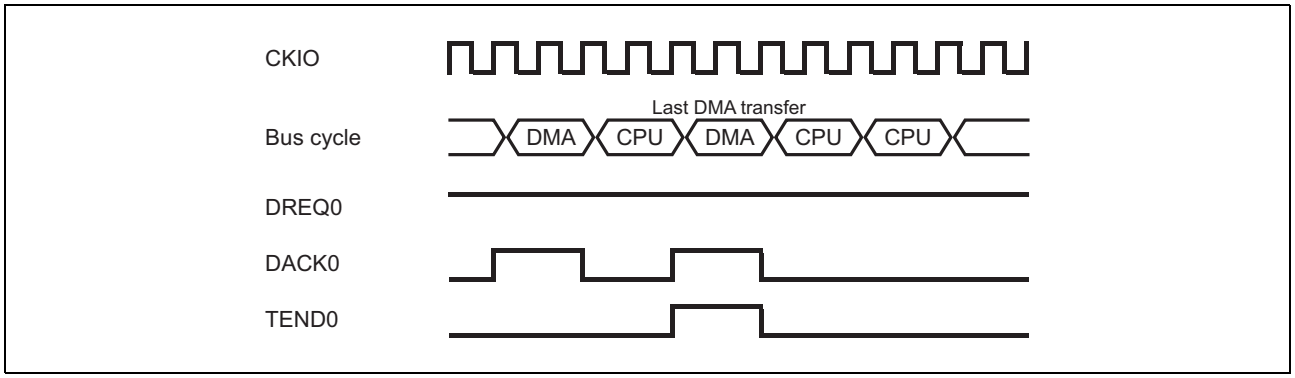

Figure 9.23 TEND0 Output Timing

9.7.7 DMA Transfer End Interrupt

The DMA transfer end interrupt is an interrupt request signal that indicates that a DMA transaction is completed.
There is an independent DMA transfer end interrupt for each channel.
When the transfer of data equivalent to the total transfer byte count loaded to the CRTB (Current Transaction Byte) is completed, 1 is set in END of the CHSTAT_n register. In this case, when 0 is set in DEM of the CHCFG_n register, the DMA transfer end interrupt is output (n = 0 to 15). (When writeback is performed in link mode, the signal is output after the writeback operation.)
When 0 is set in LV of the header in the read descriptor in link mode, 1 is set in DER of the CHSTAT_n register. In this case, when 0 is set in DIM of the header, the DMA transfer end interrupt is output.

Table 9.20 Assertion Conditions of DMA Transfer End Interrupt

Source	Condition	DMA Transfer End Interrupt Mask Signal
DMA transaction end	When the transfer of data equivalent to the total transfer byte count loaded to the CRTB (Current Transaction Byte) is completed with an OKAY response (or after the writeback operation when writeback is performed in link mode)	DEM bit of the CHCFG_n register
Descriptor invalid	When 0 is set in LV of the header in the read descriptor in link mode while 0 is set in DIM of the header	DIM bit of the header

9.7.8 DMA Error Interrupt

If an error response is received for a DMA transfer or descriptor access, the DMAC regards it as an error and stops the transfer. Upon receiving an error response, the EN bit of the CHSTAT_n register of transferring channel n is cleared to 0 and 1 is set in the ER bit (n = 0 to 15). Also, the DMA error interrupt is output.
The DMA error interrupt cannot be masked.
Once an error occurs, the data of the whole transfer cannot be guaranteed. Be sure to start the transaction again from the beginning by following the procedure below.

1. Set 1 in the SWRST bit of the CHCTRL_n register.
2. Set each register again.

9.7.9 Interval Count Function

The interval at which a DMA transfer is executed can be adjusted by setting the ITVL bit of the channel interval register (CHITVL_n). This function is intended to prevent the DMA controller from occupying the bus all the time.
When a read or write operation is completed, a countdown starts from the value set in CHITVL_n. The next internal request is not executed until the count value reaches 0.
The following figure shows an example of how this works.

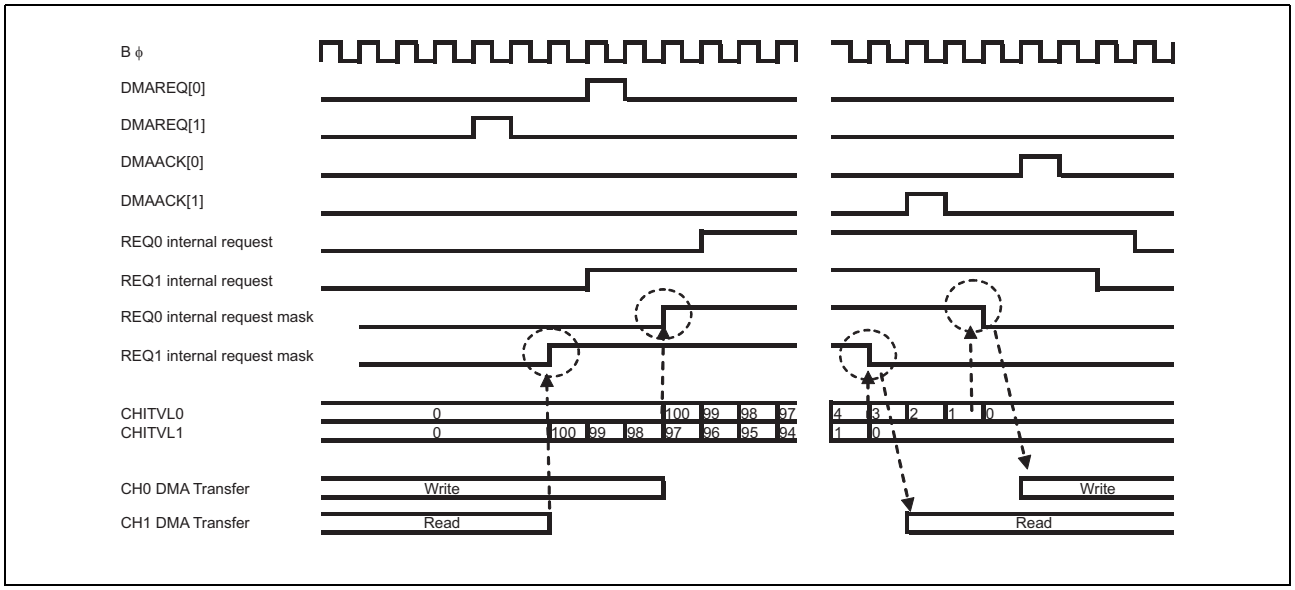

Figure 9.24 Interval Count

9.7.10 Difference in Operation Due to the Transfer Size

(1) When the Source Transfer Size Is Smaller

When the read of data equivalent to the destination data size is completed, the data is written to the destination.
The following figure shows a timing chart where the source transfer size is 8 bits and the destination transfer size is 32 bits (in the case of rising edge detection).

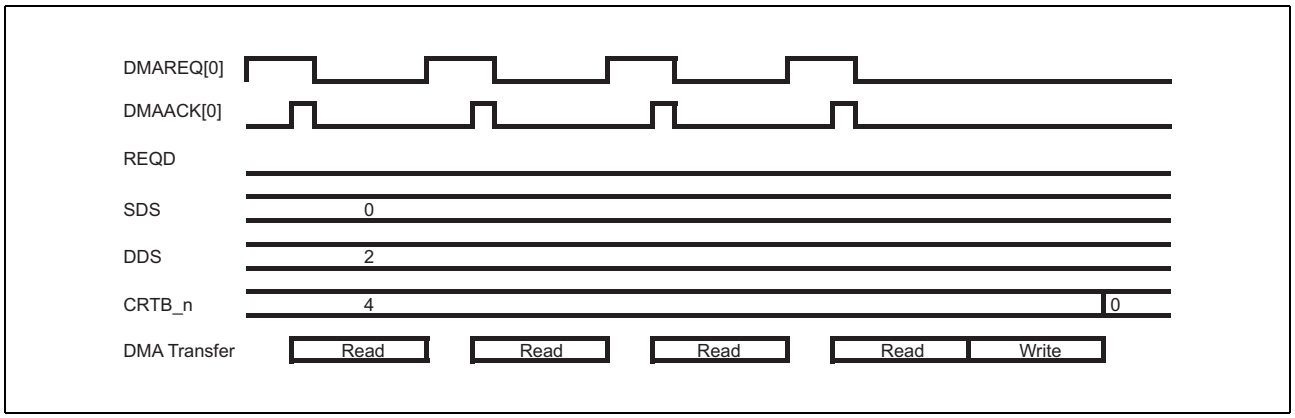

Figure 9.25 When the Source Transfer Size Is Smaller (LVL = 0, HIEN = 1, REQD = 0, SDS < DDS in CHCFG_n)

(2) When the Destination Transfer Size Is Smaller

Since the source transfer size is larger, multiple destination writes occur after a single source read. The following figure shows a timing chart where the source transfer size is 64 bits and the destination transfer size is 16 bits (in the case of rising edge detection) (1 is set in REQD of the CHCFG_n register).

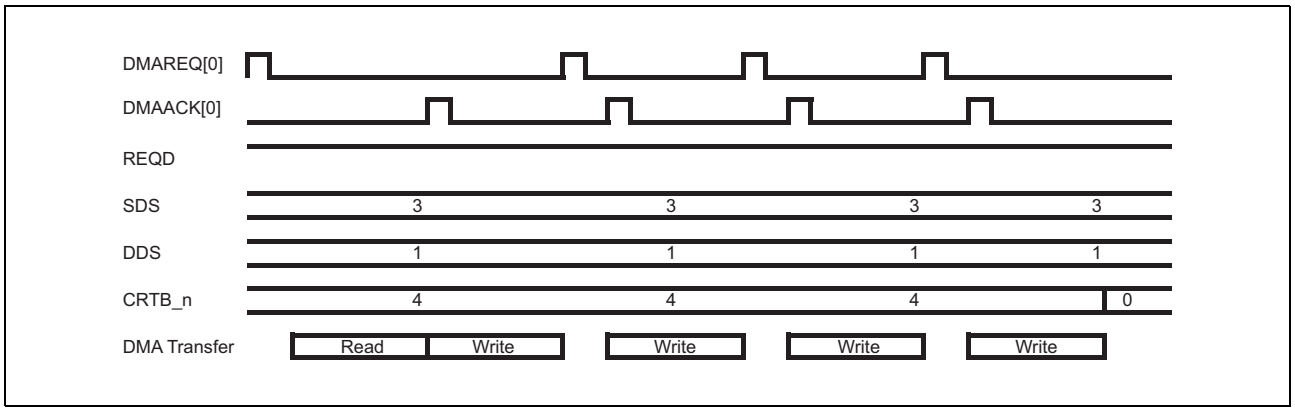

Figure 9.26 When the Destination Transfer Size Is Smaller (LVL = 0, HIEN = 1, REQD = 1, SDS > DDS in CHCFG_n)

(3) When the Source Transfer Size Is the Same as the Destination Transfer Size

Every time a DMA transfer request is detected, a source read and a destination write occur.
The following figure shows a timing chart where the source transfer size and the destination transfer size are both 8 bits (in the case of rising edge detection, with 1 set in REQD of the CHCFG_n register).

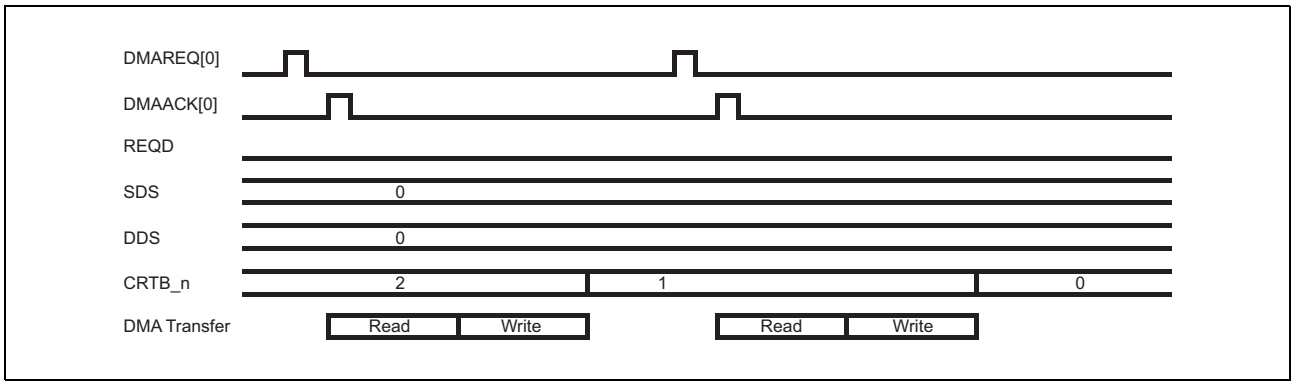

Figure 9.27 When the Source Transfer Size Is the Same as the Destination Transfer Size (LVL = 0, HIEN = 1, REQD = 0, SDS = DDS in CHCFG_n)

9.7.11 Transfer Status

The channel status register indicates the status of DMA transfer execution on a channel.

(1) Suspend

A DMA transfer can be suspended by using the SETSUS bit of CHCTRL_n. In this case, if an ongoing bus cycle exists, the DMAC waits for that cycle to end before suspending the transfer. Writing 1 in the CLRSUS bit restores the DMA transfer from the suspend status.

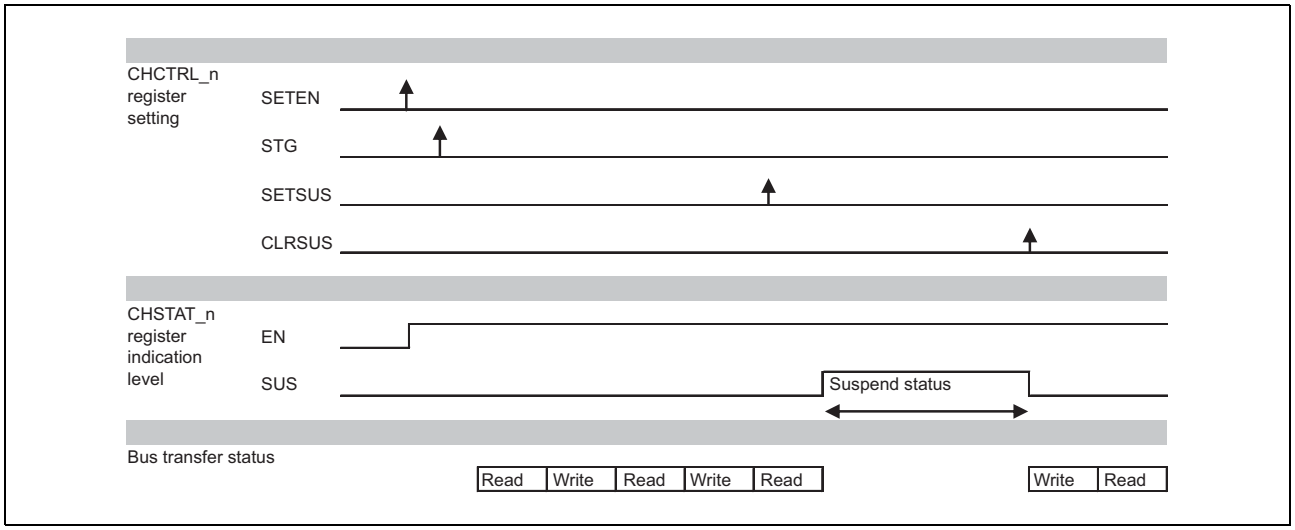

Figure 9.28 DMAC Suspend Status (Auto Request/Block Transfer)

In the above case, the DMA transfer is suspended after the read transfer is completed.
If there is any ongoing DMA transfer, the suspend status starts when that transfer is completed. To make sure that the transfer is suspended, read the CHSTAT or DSTAT_SUS register, after setting SETSUS, and check that 1 is set in the SUS bit for the relevant channel.

(2) Transfer Stop

If you write 1 to CLREN while a DMA transaction is in progress, you can stop the DMA transaction for the corresponding channel. For the post-stop processing, two modes are supported: one sweeps out the data remaining in the buffer when the transaction is stopped (SBE = 1) and the other does not (SBE = 0). One of these modes can be selected using the SBE bit of the CHCFG_n register. By default, SBE is set to 0.
When this sweep mode is enabled and CLREN is set to 1, and if a DMA transaction is stopped with data remaining in the DMAC buffer, the transaction is completed after the DMAC sweeps the data.

(a) Transfer Stop (Buffer Sweep Disabled - SBE = 0)

If you set 1 in CLREN during a DMA transfer, the DMA transfer is stopped. The stop timing depends on the value set in REQD. After stopping a DMA transfer, be sure to set 1 in SWRST to clear the DMA internal status before setting the next transfer.

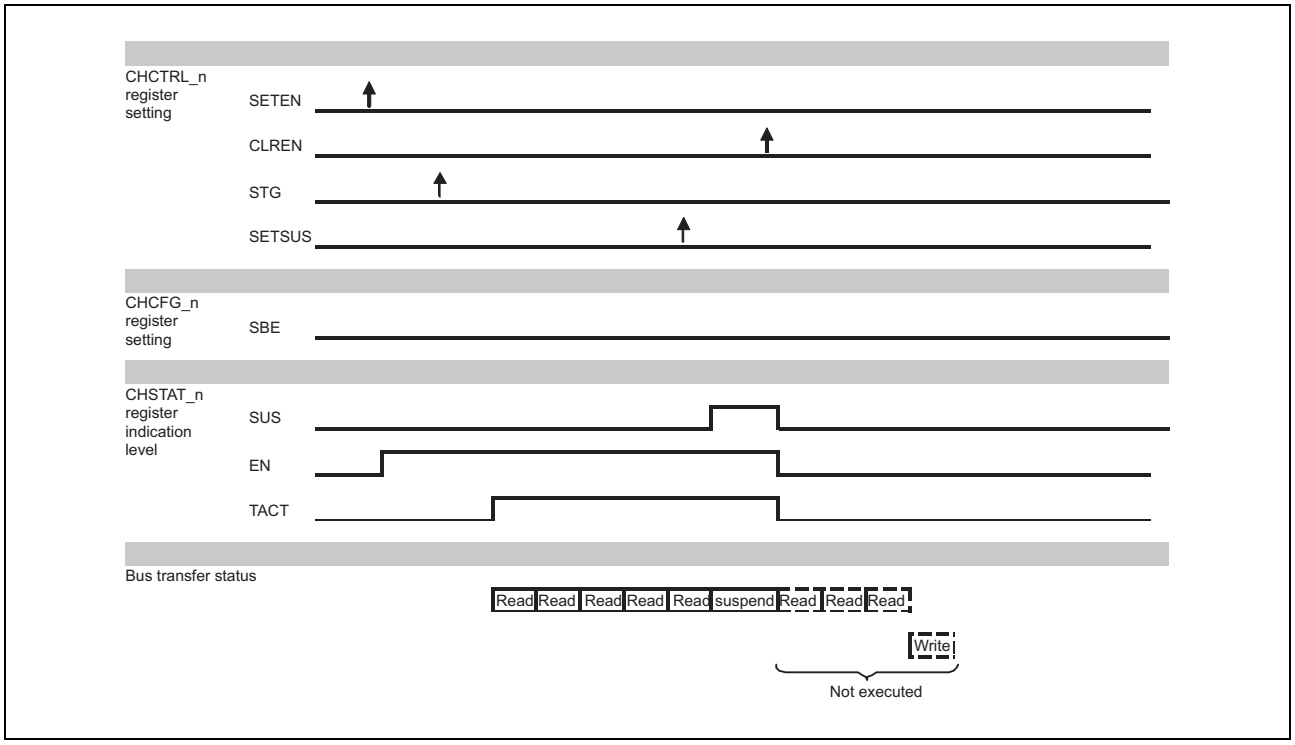

Figure 9.29 DMAC Transfer Stop

- When the TACT bit is set to 0, you can check that the channel has been brought to a complete stop.
- If you stop an ongoing DMA transfer before it is completed, the DMA transfer end interrupt is not asserted.
- If 0 is set in REQD, the DMA transfer is stopped when the next read is completed. (If the buffer contains any data that can be written, the DMA transfer is stopped after the data is written.)
- If 1 is set in REQD, the DMA transfer is stopped when the next write is completed.

(b) Transfer Stop (Buffer Sweep Enabled - SBE = 1)

If 1 is set in CLREN during a DMA transfer, the DMA transfer is stopped. When 0 is set in REQD, the DMA transfer is stopped after the DMAC sweeps (writes) the already read data. If 1 is set in REQD to use hardware requests, do not use the sweep mode. After stopping a DMA transfer, be sure to set 1 in SWRST to clear the DMAC internal status before setting the next transfer.

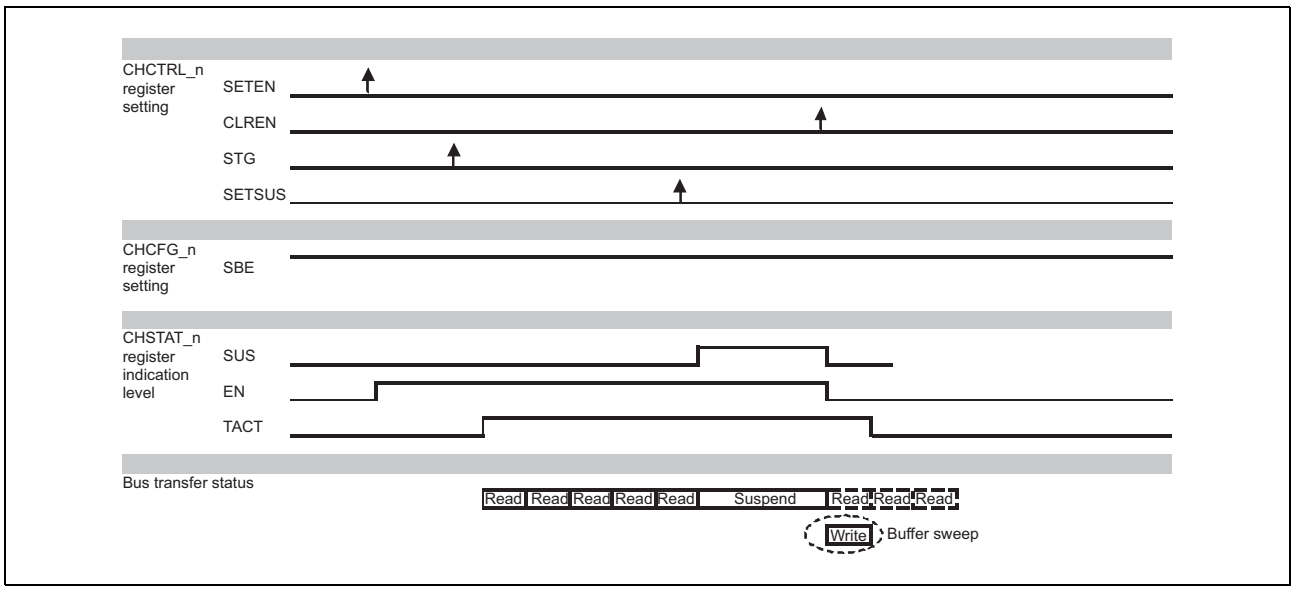

Figure 9.30 DMA Transfer Stop (Buffer Sweep Mode)

- When the TACT bit is set to 0, you can check that the channel has been brought to a complete stop.
- If you stop a transfer in sweep mode (SBE = 1) during the fifth read transfer by setting SETSUS and then CLREN, the read data is written before the DMA transfer is stopped.

(c) Channel Stop Check Method

Even when you clear the EN bit to 0, you cannot stop the DMA transfer immediately, if the bus is already executing the transfer. Therefore, in order to make sure that the DMAC has been brought to a complete stop, you need to check that the EN bit and TACT bit are both set to 0.

(d) Transfer Stop Procedure

The transfer stop procedure is described below.

1. Set 1 in SETSUS of CHCTRL_n.
2. Repeat polling until the SUS bit of CHSTAT_n is set to 1. (If EN is already set to 0, the DMAC has already been stopped. Go to step 6.)
3. Set 1 in CLREN of CHCTRL_n.
4. When 0 is set in SBE, the transfer is stopped according to the value of REQD. When 1 is set in SBE, the sweep mode is enabled. When 1 is set in SBE, set 0 in REQD.
5. Read CHSTAT_n to check that 0 is set in the TACT bit. When TACT is set to 0, it means that the DMAC has been brought to a complete stop. When TACT is set to 1, repeat polling until this bit is set to 0.
6. To execute the next DMA transfer after stopping a transfer, be sure to set 1 in the SWRST (software reset) bit of CHCTRL_n before the next DMA transfer starts.

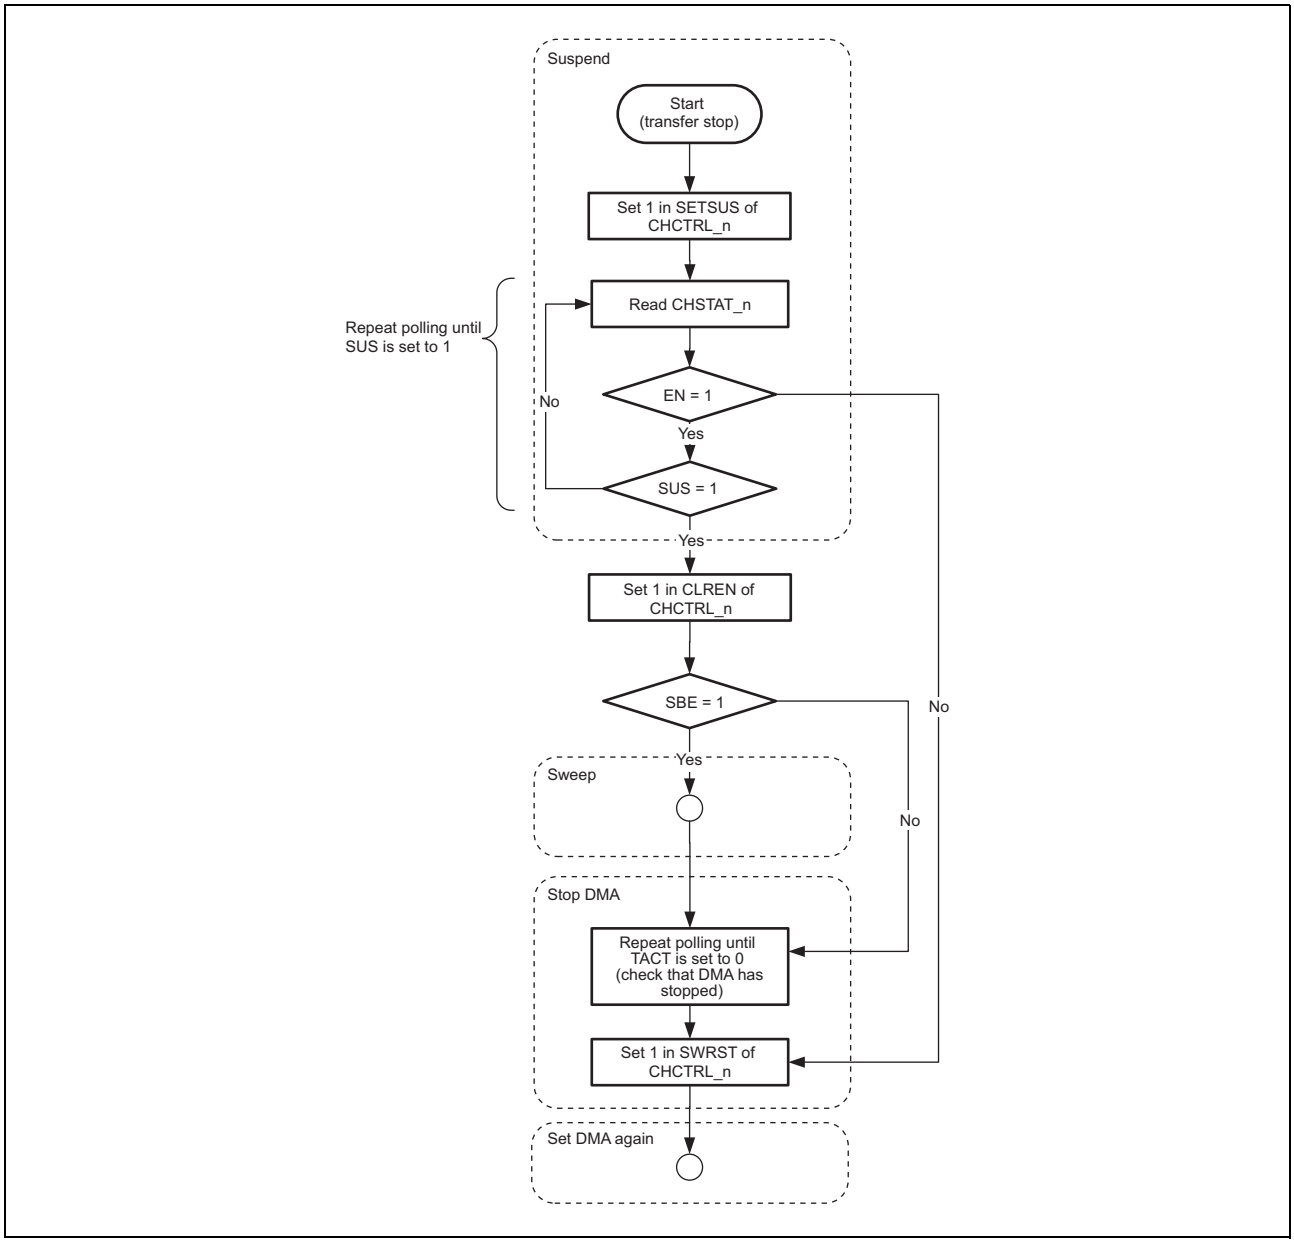

Figure 9.31 Transfer Stop Flow

9.8 DMA Setting Examples

Setting examples applicable when DMA transfer is executed using the direct memory access controller are shown in the following.
The transfer conditions for these setting examples are as follows.

Table 9.21 Transfer Condition List for DMA Transfer Setting Examples

	DMA Mode	Transfer Mode	Transfer Request
Setting example 1	Register	Single	Hardware
Setting example 2	Register	Block	Software
Setting example 3	Register (continuous execution)	Block	Software
Setting example 4	Link	Block	Software

For details of the settings, see the individual setting examples.

9.8.1 Setting Example 1 (Register Mode/Hardware Request)

The following table shows a setting example applicable when DMA transfer is executed using the settings shown below.

Table 9.22 DMA Transfer Setting Example 1

Item		Description	
Channel used		3	
DMA mode		Register	
Transfer mode		Single transfer	
Register set used		Next0	
Source/destination		Source	Destination
	Start address	1111_0000H	2222_0000H
	Address direction	Increment	Increment
	Data size	32 bits	32 bits
DMA transfer byte count		64 bytes	
DMA transfer request		Rising edge detection by hardware	
DMAACK signal		Level output during read	
DMA transfer end interrupt mask		Not masked	
CACHE setting		Default value	

Setting example 1

N0SA = 1111_0000H (source address)
N0DA = 2222_0000H (destination address)
N0TB = 0000_0040H (transfer byte count)

CHCFG = 0002_2123H (configuration)
CHITVL = 0000_0000H (interval)
CHEXT = 0000_0000H (CACHE setting)

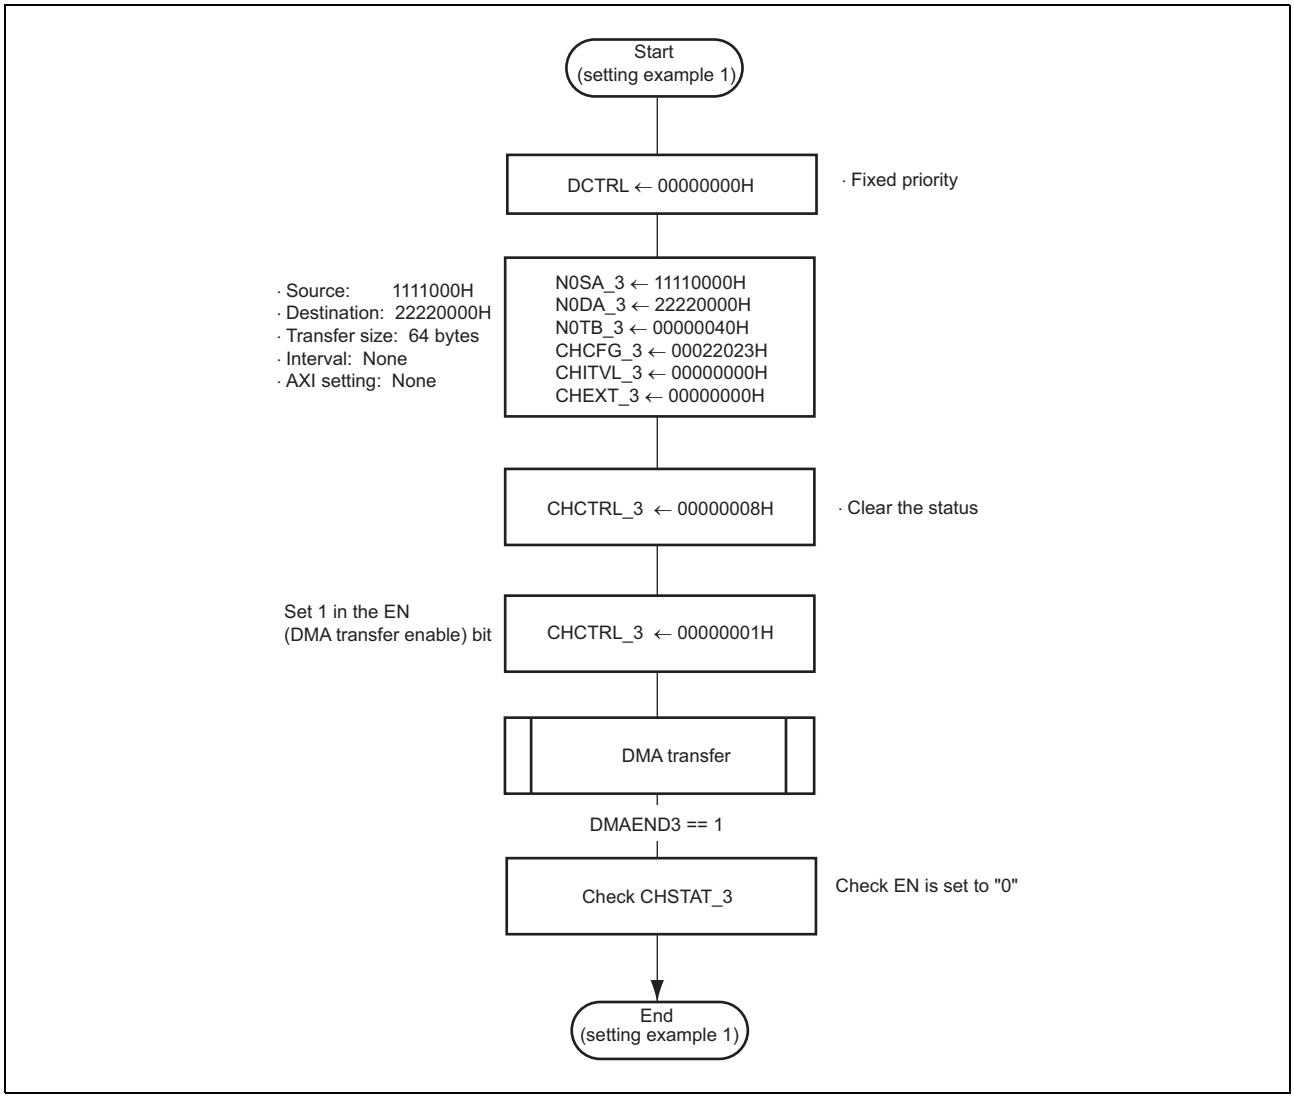

Figure 9.32 Setting Example 1

9.8.2 Setting Example 2 (Register Mode/Software Request)

The following table shows a setting example applicable when DMA transfer is executed using the settings shown below.

Table 9.23 DMA Transfer Setting Example 2

Item		Description	
Channel used		2	
Priority control		Round robin	
DMA mode		Register	
Transfer mode		Block transfer	
Register set used		Next1	
Source/destination		Source	Destination
	Start address	0FFF_E000H	3333_0000H
	Address direction	Increment	Increment
	Data size	8 bits	256 bits
DMA transfer byte count		128 bytes	
DMA transfer request		Auto request	
DMAACK signal		Masked	
DMA transfer end interrupt mask		Not masked	
CACHE setting		Default value	

Setting example 2

DCTRL = 0000_0001H (DMA setting)

N1SA = 0FFF_E000H (source address)
N1DA = 3333_0000H (destination address)
N1TB = 0000_0080H (transfer byte count)

CHCFG = 1045_0402H (configuration)
CHITVL = 0000_0000H (interval)
CHEXT = 0000_0000H (CACHE setting)

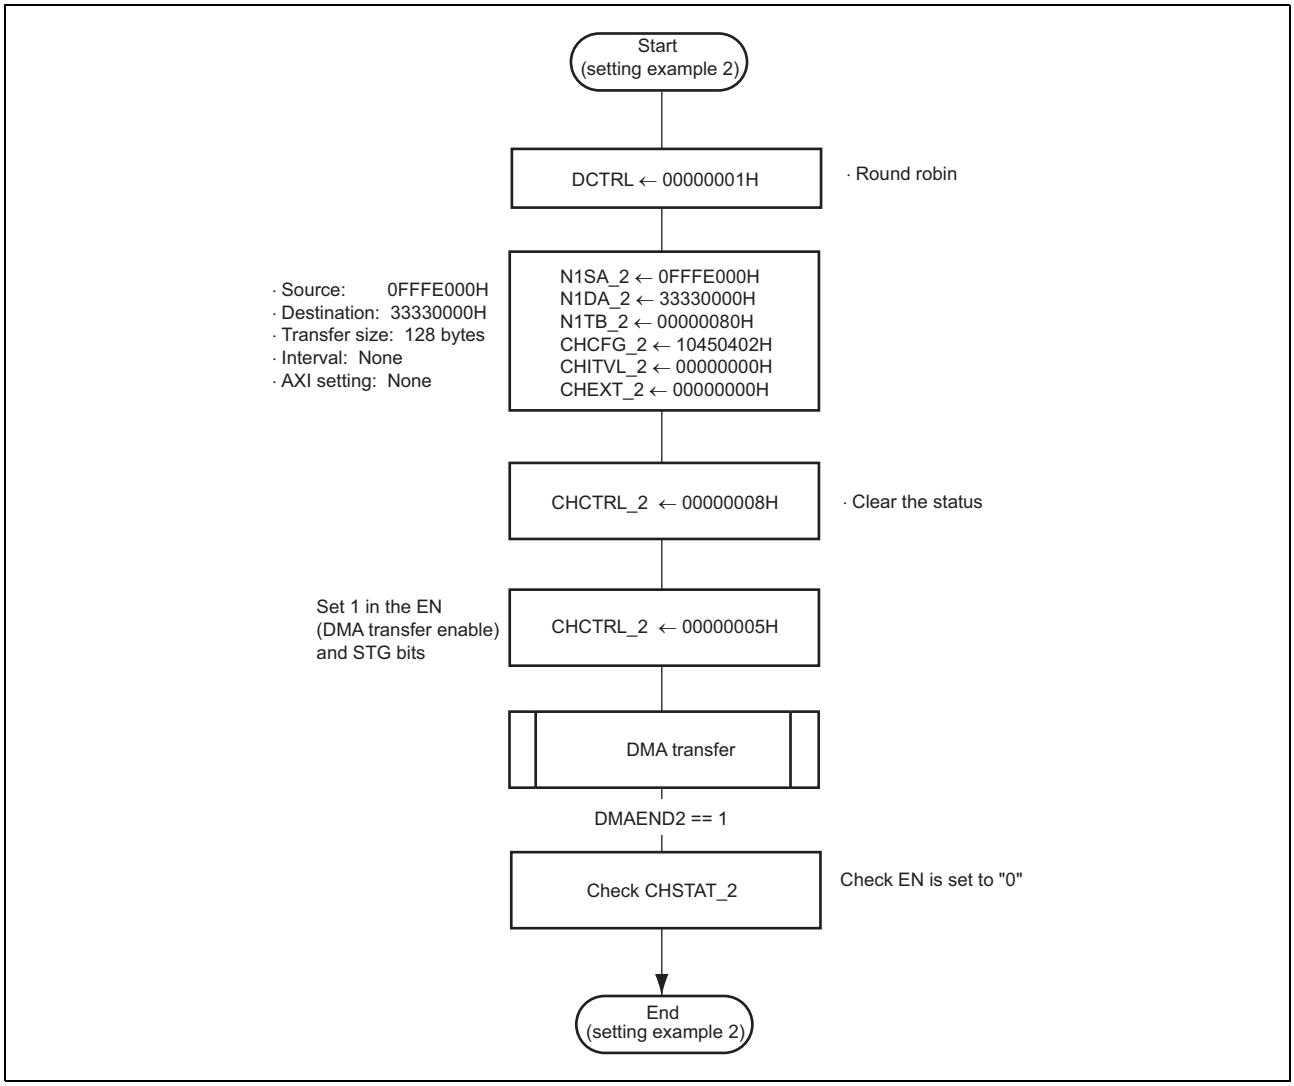

Figure 9.33 Setting Example 2

9.8.3 Setting Example 3 (Register Mode/Continuous Execution)

The following table shows a setting example applicable when DMA transfer is executed using the settings shown below.

Table 9.24 DMA Transfer Setting Example 3

Item		Description	
Channel used		1	
Priority control		Round robin	
DMA mode		Register	
Transfer mode		Block transfer	
Register set used		Use Next0 and then Next1 continuously	
Next0		Source	Destination
	Start address	1111_0000H	3333_0000H
	Address direction	Fixed	Fixed
	Data size	32 bits	512 bits
	DMA transfer byte count	512 bytes	
Next1		Source	Destination
	Start address	2222_0000H	4444_0000H
	Address direction	Fixed	Fixed
	Data size	32 bits	512 bits
	DMA transfer byte count	2048 bytes	
DMA transfer request		Auto request	
DMAACK signal		Not output	
DMA transfer end interrupt mask		Mask the DMA transfer end interrupt upon completion of Next0	
CACHE setting		Default value	

Setting example 3

DCTRL = 0000_0001H (DMA setting)

N0SA = 1111_0000H (source address)
N0DA = 3333_0000H (destination address)
N0TB = 0000_0200H (transfer byte count)

N1SA = 2222_0000H (source address)
N1DA = 4444_0000H (destination address)
N1TB = 0000_0800H (transfer byte count)

CHCFG = 6176_2001H (configuration)
CHITVL = 0000_0000H (interval)
CHEXT = 0000_0000H (CACHE setting)

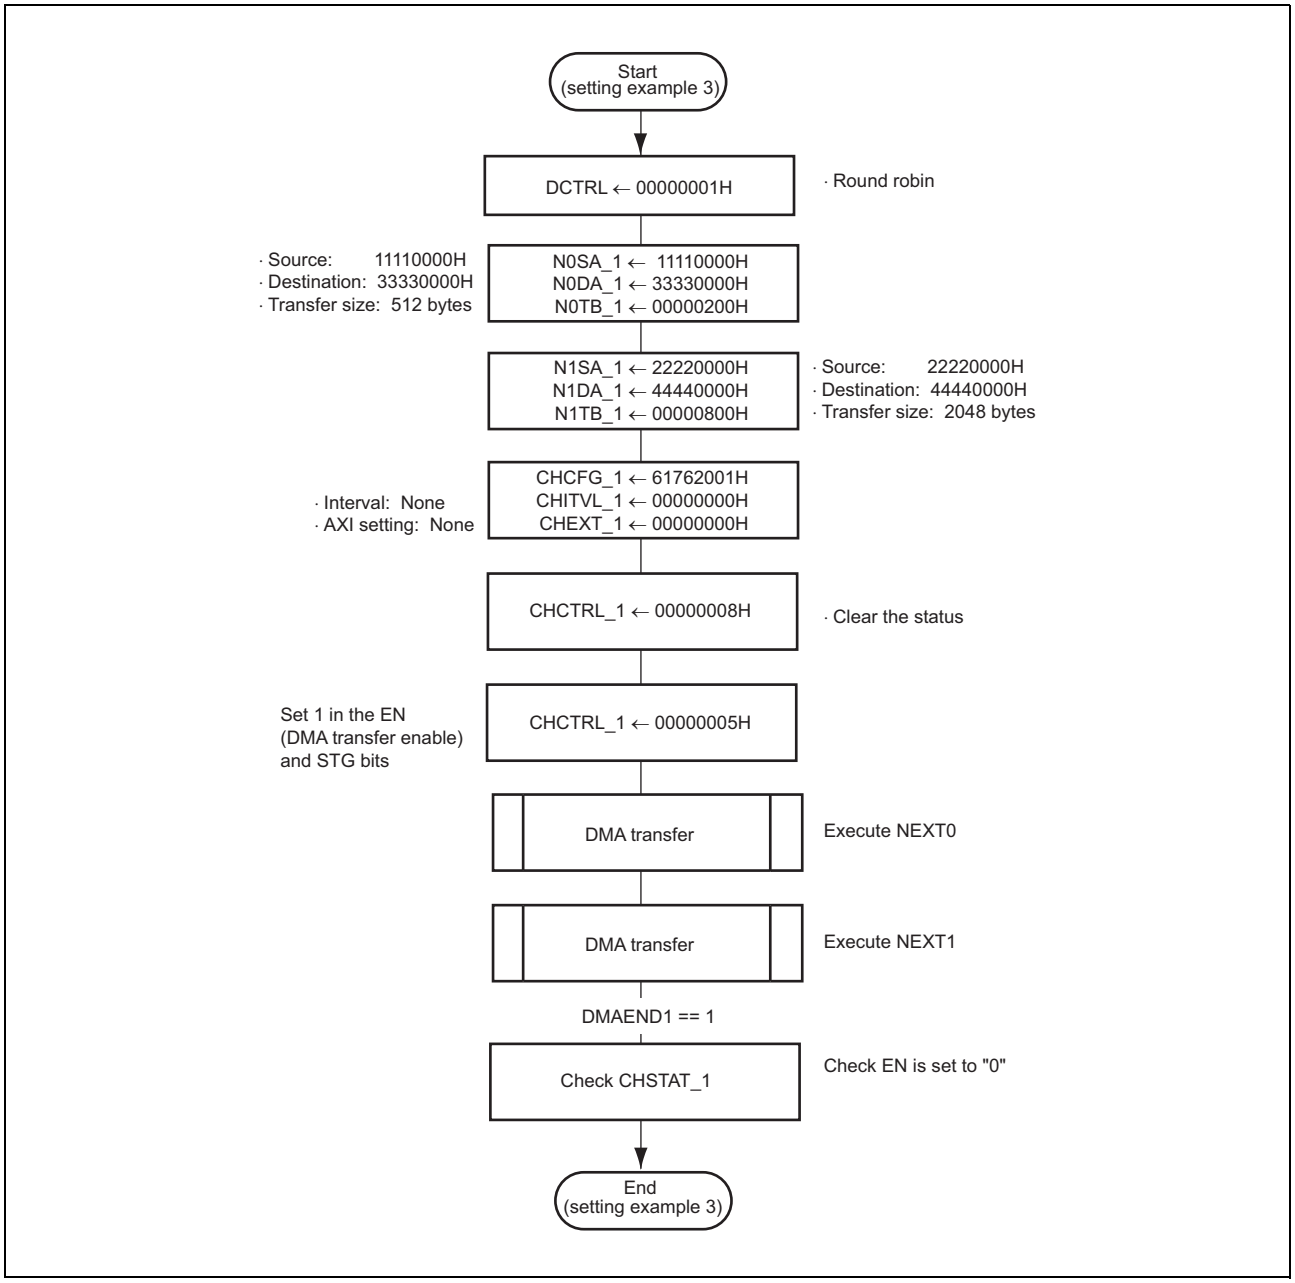

Figure 9.34 Setting Example 3

9.8.4 Setting Example 4 (Link Mode)

The following table shows a setting example applicable when DMA transfer is executed using the settings shown below.

Table 9.25 DMA Transfer Setting Example 4

Item	Description
Channel used	0
Priority control	Round robin
DMA mode	Link
Transfer mode	Block transfer
Register set used	—
Descriptor start address	0000_1000H

Table 9.26 DMA Transfer Setting Example 4 (Descriptor 1)

Item		Description	
Descriptor start address		0000_1000H	
Next descriptor start address		0000_2000H	
Transfer mode		Block transfer	
Next0		Source	Destination
	Start address	1111_0000H	3333_0000H
	Address direction	Increment	Increment
	Data size	32 bits	32 bits
	DMA transfer byte count	2048 bytes	
DMA transfer request		Auto request trigger (STG)	
DMAACK signal		Not output	
DMA transfer end interrupt mask		Masked	
CACHE setting		Default value	
header			
	DMA interrupt when LV = 1	Issued (DIM = 0)	
	LV writeback	Done (WBD = 0)	
	Next link address	Available (LE = 0)	
	Descriptor valid	Valid (LV = 1)	

Table 9.27 DMA Transfer Setting Example 4 (Descriptor 2)

Item		Description	
Descriptor start address		0000_2000H	
Next descriptor start address		0000_5000H	
Transfer mode		Block transfer	
Next0		Source	Destination
	Start address	4444_0000H	5555_0000H
	Address direction	Increment	Increment
	Data size	64 bits	256 bits
	DMA transfer byte count	1024 bytes	
DMA transfer request		Auto request trigger (STG)	
DMAACK signal		Not output	
DMA transfer end interrupt mask		Masked

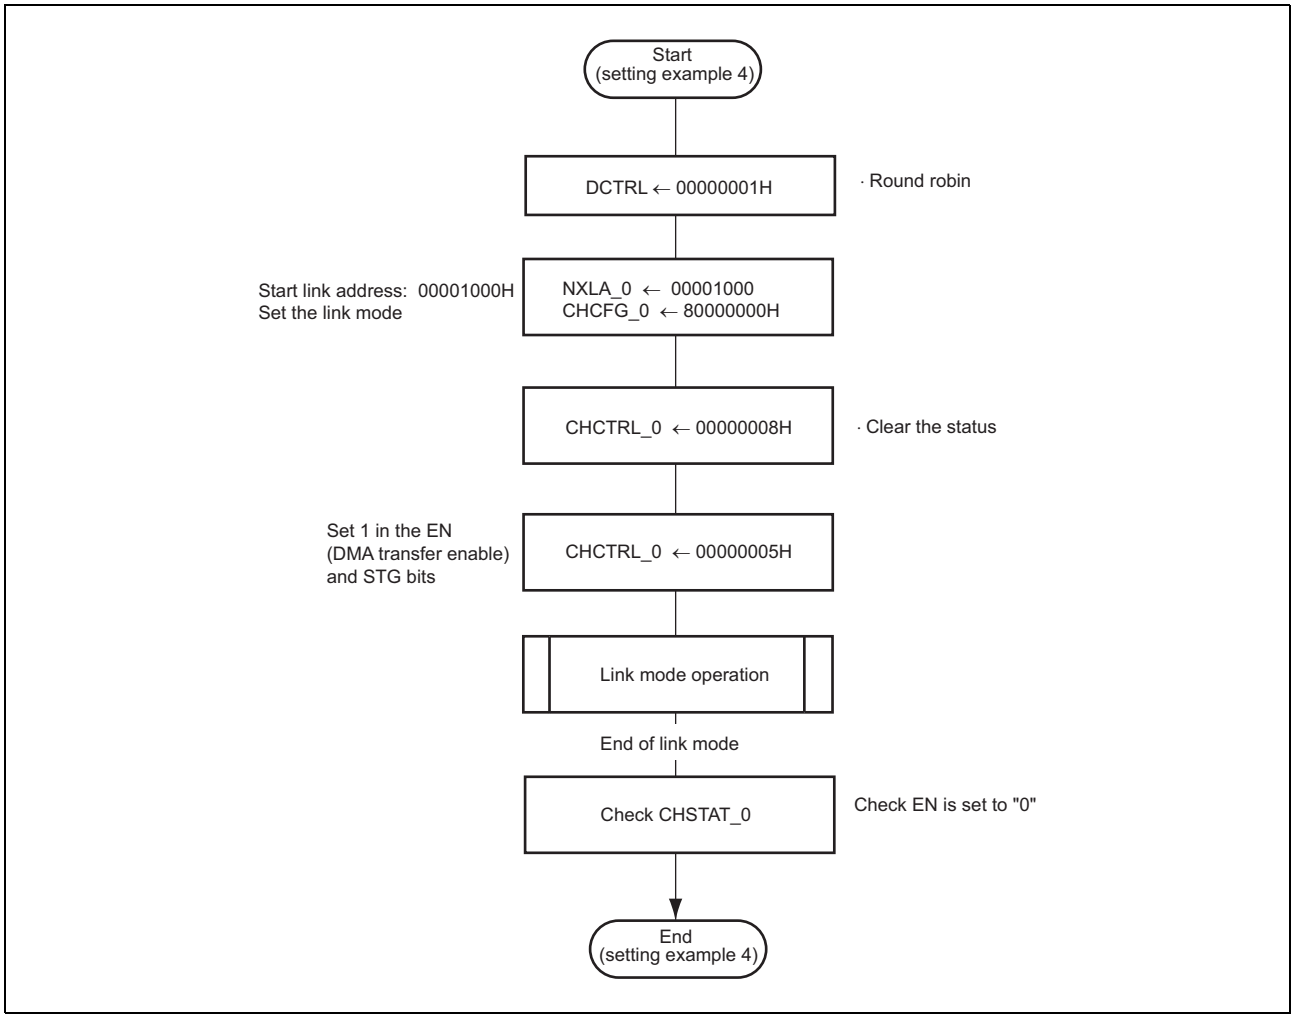

Figure 9.35 Setting Example 4

9.8.5 Next Register Set Continuous Execution Setting

The following figure shows the flowchart for executing DMA transfers continuously by using two Next Register Sets in register mode. While a DMA transaction is being executed using one Next Register Set, the other Next Register Set is set in order to continue to execute DMA transfers.

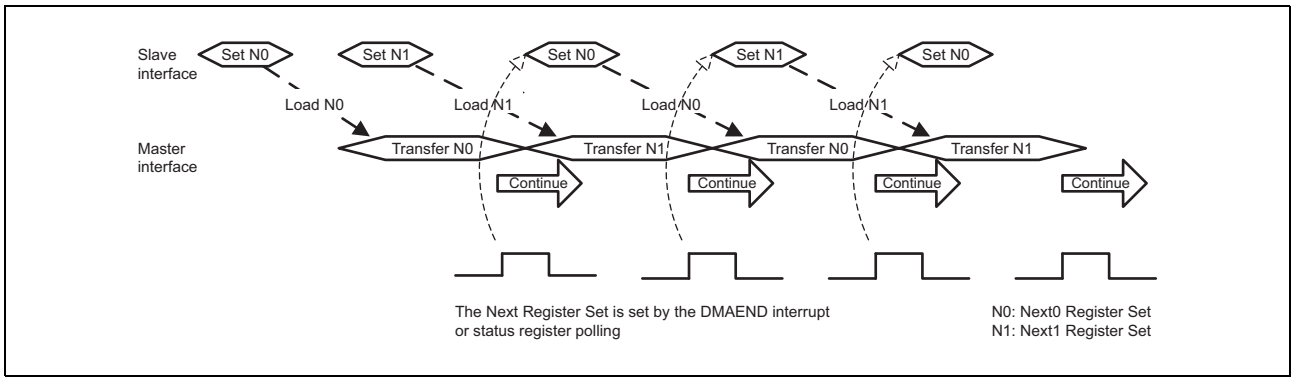

Figure 9.36 Image of Next Register Set Continuous Execution

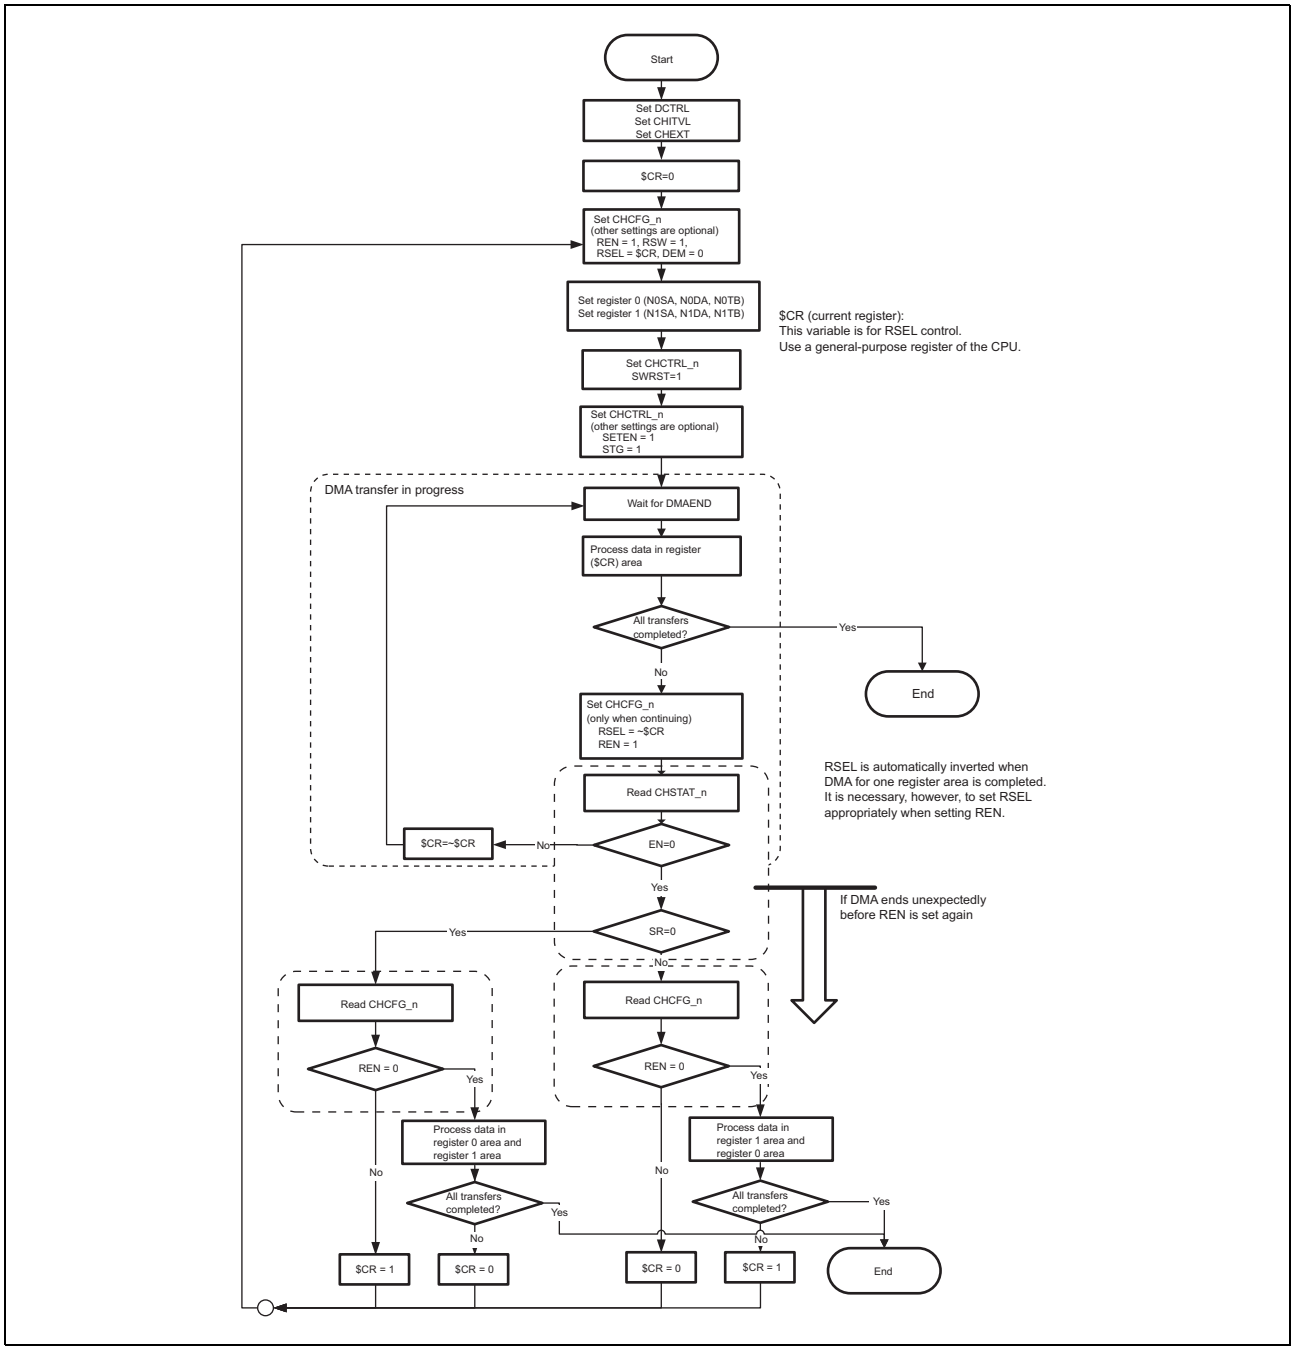

Figure 9.37 Example of Continuous DMA Execution by Using a Next Register Set

- Supplementary information
  First, save the data of the register sets to be used for DMA transfers (0 (N0SA, N0DA, and N0TB) and 1 (N1SA, N1DA, and N1TB)) to a general-purpose register of the CPU (the values of this register is referred to as $CR for the sake of convenience).
  Each time the DMA transfers for one register set are completed (the DMA transfer end interrupt is output), REN is automatically cleared to 0. In order to continue to execute DMA transfers, it is necessary to set REN of the CHCFG_n register every time the DMA transfer end interrupt is asserted. This register also contains the RSEL bit, and the value of this bit needs to be set appropriately as well. Therefore, use $CR.
  In this mode, two Next Register Sets are executed continuously. However, if CLREN is not set before the DMA transaction is completed (the next DMA transfer end interrupt is output), continuous execution stops. In this case, you can check how much of data has been transferred, by reading the SR and EN bits of the CHSTAT_n register and the REN bit of the CHCFG_n register. To restart the DMA transaction, follow the flowchart shown above.

9.9 Note

9.9.1 Divided Output of DACK0 and TEND0

When transferring 4 bytes or more to an 8-bit or 16-bit external device or transferring 2 bytes or more to an 8-bit external device, each DMA transfer unit is divided into multiple bus cycles. Note that, if the setting is such that DMA transfer is divided into multiple bus cycles and $\overline{CS}$ is negated between bus cycles, the DACK0 output and the TEND0 output is divided to align data as with $\overline{CS}$. Figure 9.38 shows an example.

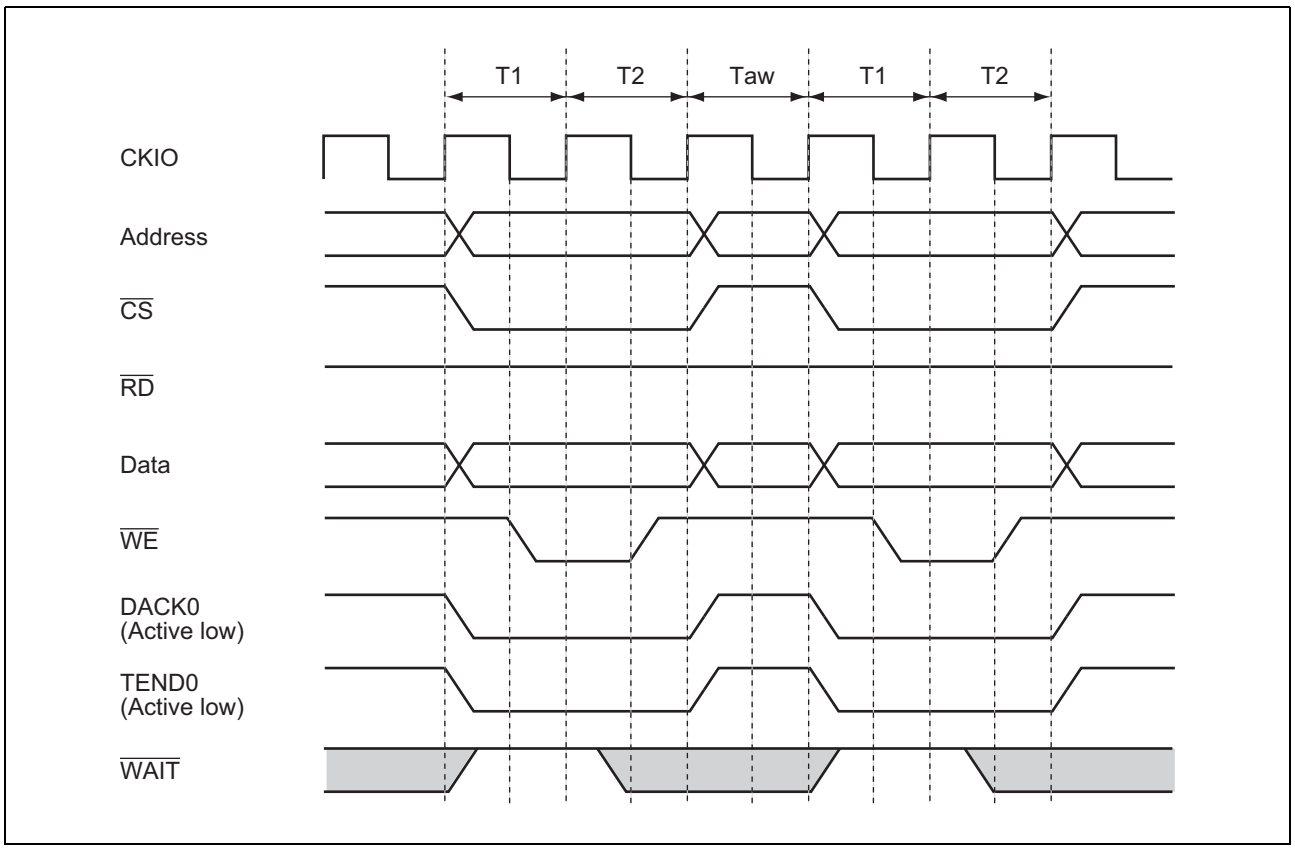

Figure 9.38 Example of TEND0 Divided Output Timing

9.9.2 TEND0 Not Output

Note that TEND0 may not be output depending on the combination of the bits DDS[3:0], SDS[3:0] and REQD in the CHCFG_0 register.

Table 9.30 shows when TEND0 is not output and Figure 9.39 shows an operation example.

Table 9.30 Bit Combination when TEND0 Is Not Output

CHCFG_0 Register			
REQD	**DDS**	**SDS**	**TEND0 Output**
1	—	—	Output
0	DDS > SDS		Output
	DDS = SDS		Output
	DDS < SDS		Not output

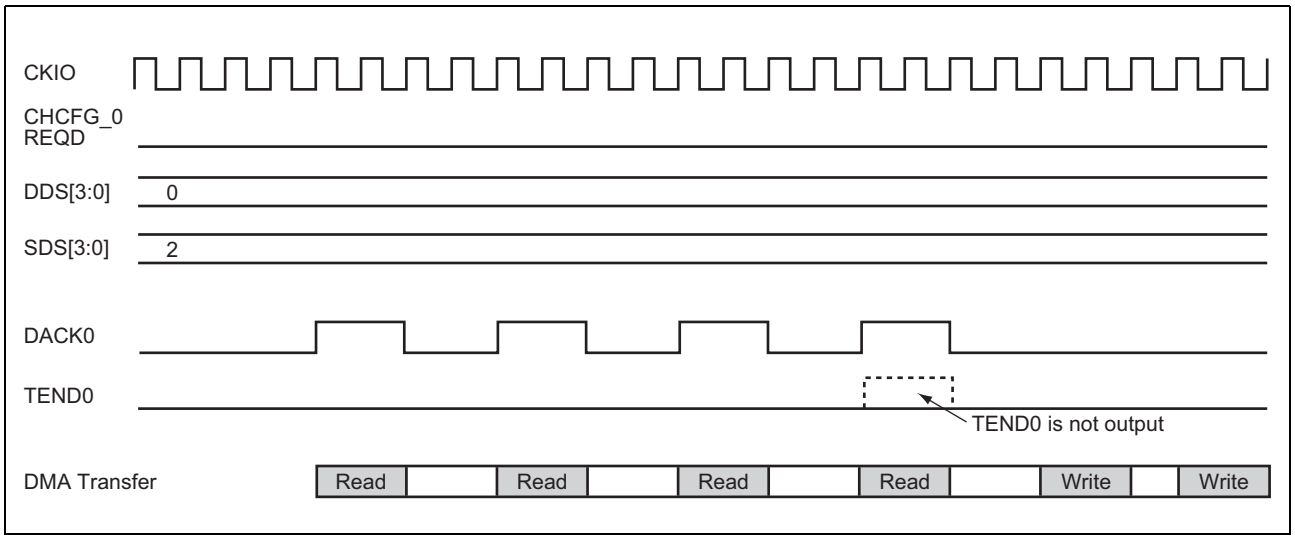

Figure 9.39 TEND0 Not Output

9.9.3 Atomic Access (ARLOCK[1:0] and AWLOCK[1:0])

This module does not support atomic (locked or exclusive) access, that is, it only supports normal access.
Signals ARLOCK[1:0] and AWLOCK[1:0] are fixed as follows and cannot be modified.
ARLOCK[1:0], AWLOCK[1:0]: 00 (normal access)

10. Multi-Function Timer Pulse Unit 2

This LSI has an on-chip multi-function timer pulse unit 2 that comprises five 16-bit timer channels.

10.1 Features

- Maximum 16 pulse input/output lines
- Selection of eight counter input clocks for each channel
- The following operations can be set:
  - Waveform output at compare match
  - Input capture function
  - Counter clear operation
  - Multiple timer counters (TCNT) can be written to simultaneously
  - Simultaneous clearing by compare match and input capture is possible
  - Register simultaneous input/output is possible by synchronous counter operation
  - A maximum 12-phase PWM output is possible in combination with synchronous operation
- Buffer operation settable for channels 0, 3, and 4
- Phase counting mode settable independently for each of channels 1 and 2
- Cascade connection operation
- Fast access via internal 16-bit bus
- 25 interrupt sources
- Automatic transfer of register data
- A/D converter start trigger can be generated
- Module standby mode can be settable
- A total of six-phase waveform output, which includes complementary PWM output, and positive and negative phases of reset PWM output by interlocking operation of channels 3 and 4, is possible.
- AC synchronous motor (brushless DC motor) drive mode using complementary PWM output and reset PWM output is settable by interlocking operation of channels 0, 3, and 4, and the selection of two types of waveform outputs (chopping and level) is possible.
- In complementary PWM mode, interrupts at the crest and trough of the counter value and A/D converter start triggers can be skipped.

10.3.1 Timer Control Register (TCR)

The TCR registers are 8-bit readable/writable registers that control the TCNT operation for each channel. This module has a total of five TCR registers, one each for channels 0 to 4. TCR register settings should be conducted only when TCNT operation is stopped.

Bit:	7	6	5	4	3	2	1	0
	CCLR[2:0]			CKEG[1:0]		TPSC[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	CCLR[2:0]	000	R/W	Counter Clear 0 to 2 These bits select the TCNT counter clearing source. See Table 10.4 and Table 10.5 for details.
4, 3	CKEG[1:0]	00	R/W	Clock Edge 0 and 1 These bits select the input clock edge. When the input clock is counted using both edges, the input clock period is halved (e.g. P0ϕ/4 both edges = P0ϕ/2 rising edge). If phase counting mode is used on channels 1 and 2, this setting is ignored and the phase counting mode setting has priority. Internal clock edge selection is valid when the input clock is P0ϕ/4 or slower. When P0ϕ/1, or the overflow/underflow of another channel is selected for the input clock, although values can be written, counter operation compiles with the initial value. 00: Count at rising edge 01: Count at falling edge 1x: Count at both edges
2 to 0	TPSC[2:0]	000	R/W	Time Prescaler 0 to 2 These bits select the TCNT counter clock. The clock source can be selected independently for each channel. See Table 10.6 to Table 10.9 for details.

[Legend]
x: Don't care

Table 10.4 CCLR0 to CCLR2 (Channels 0, 3, and 4)

Channel	Bit 7 CCLR2	Bit 6 CCLR1	Bit 5 CCLR0	Description
0, 3, 4	0	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRA compare match/input capture
		1	0	TCNT cleared by TGRB compare match/input capture
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation*1
	1	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRC compare match/input capture*2
		1	0	TCNT cleared by TGRD compare match/input capture*2
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation*1

Note 1. Synchronous operation is set by setting the SYNC bit in TSYR to 1.
Note 2. When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.

Table 10.5 CCLR0 to CCLR2 (Channels 1 and 2)

Channel	Bit 7 Reserved*2	Bit 6 CCLR1	Bit 5 CCLR0	Description
1, 2	0	0	0	TCNT clearing disabled
			1	TCNT cleared by TGRA compare match/input capture
		1	0	TCNT cleared by TGRB compare match/input capture
			1	TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation*1

Note 1. Synchronous operation is selected by setting the SYNC bit in TSYR to 1.
Note 2. Bit 7 is reserved in channels 1 and 2. It is always read as 0 and cannot be modified.

Table 10.6 TPSC0 to TPSC2 (Channel 0)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
0	0	0	0	Internal clock: counts on P0ϕ/1
			1	Internal clock: counts on P0ϕ/4
		1	0	Internal clock: counts on P0ϕ/16
			1	Internal clock: counts on P0ϕ/64
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	External clock: counts on TCLKC pin input
			1	External clock: counts on TCLKD pin input

Table 10.7 TPSC0 to TPSC2 (Channel 1)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
1	0	0	0	Internal clock: counts on P0ϕ/1
			1	Internal clock: counts on P0ϕ/4
		1	0	Internal clock: counts on P0ϕ/16
			1	Internal clock: counts on P0ϕ/64
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	Internal clock: counts on P0ϕ/256
			1	Counts on TCNT_2 overflow/underflow

Note: This setting is ignored when channel 1 is in phase counting mode.

Table 10.8 TPSC0 to TPSC2 (Channel 2)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
2	0	0	0	Internal clock: counts on P0ϕ/1
			1	Internal clock: counts on P0ϕ/4
		1	0	Internal clock: counts on P0ϕ/16
			1	Internal clock: counts on P0ϕ/64
	1	0	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input
		1	0	External clock: counts on TCLKC pin input
			1	Internal clock: counts on P0ϕ/1024

Note: This setting is ignored when channel 2 is in phase counting mode.

Table 10.9 TPSC0 to TPSC2 (Channels 3 and 4)

Channel	Bit 2 TPSC2	Bit 1 TPSC1	Bit 0 TPSC0	Description
3, 4	0	0	0	Internal clock: counts on P0ϕ/1
			1	Internal clock: counts on P0ϕ/4
		1	0	Internal clock: counts on P0ϕ/16
			1	Internal clock: counts on P0ϕ/64
	1	0	0	Internal clock: counts on P0ϕ/256
			1	Internal clock: counts on P0ϕ/1024
		1	0	External clock: counts on TCLKA pin input
			1	External clock: counts on TCLKB pin input

10.3.2 Timer Mode Register (TMDR)

The TMDR registers are 8-bit readable/writable registers that are used to set the operating mode of each channel. This module has five TMDR registers, one each for channels 0 to 4. TMDR register settings should be changed only when TCNT operation is stopped.

Bit:	7	6	5	4	3	2	1	0
	-	BFE	BFB	BFA	MD[3:0]			
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	BFE	0	R/W	Buffer Operation E Specifies whether TGRE_0 and TGRF_0 are to operate in the normal way or to be used together for buffer operation. TGRF compare match is generated when TGRF is used as the buffer register. In channels 1 to 4, this bit is reserved. It is always read as 0 and the write value should always be 0. 0: TGRE_0 and TGRF_0 operate normally 1: TGRE_0 and TGRF_0 used together for buffer operation
5	BFB	0	R/W	Buffer Operation B Specifies whether TGRB is to operate in the normal way, or TGRB and TGRD are to be used together for buffer operation. When TGRD is used as a buffer register, TGRD input capture/output compare is not generated in a mode other than complementary PWM. In channels 1 and 2, which have no TGRD, bit 5 is reserved. It is always read as 0 and cannot be modified. 0: TGRB and TGRD operate normally 1: TGRB and TGRD used together for buffer operation
4	BFA	0	R/W	Buffer Operation A Specifies whether TGRA is to operate in the normal way, or TGRA and TGRC are to be used together for buffer operation. When TGRC is used as a buffer register, TGRC input capture/output compare is not generated in a mode other than complementary PWM. TGRC compare match is generated when in complementary PWM mode. When compare match for channel 4 occurs during the Tb period in complementary PWM mode, TGFC is set. Therefore, set the TGIEC bit in the timer interrupt enable register 4 (TIER_4) to 0. In channels 1 and 2, which have no TGRC, bit 4 is reserved. It is always read as 0 and cannot be modified. 0: TGRA and TGRC operate normally 1: TGRA and TGRC used together for buffer operation
3 to 0	MD[3:0]	0000	R/W	Modes 0 to 3 These bits are used to set the timer operating mode. See Table 10.10 for details.

Table 10.10 Setting of Operation Mode by Bits MD0 to MD3

Bit 3 MD3	Bit 2 MD2	Bit 1 MD1	Bit 0 MD0	Description
0	0	0	0	Normal operation
			1	Setting prohibited
		1	0	PWM mode 1
			1	PWM mode 2*1
	1	0	0	Phase counting mode 1*2
			1	Phase counting mode 2*2
		1	0	Phase counting mode 3*2
			1	Phase counting mode 4*2
1	0	0	0	Reset synchronous PWM mode*3
			1	Setting prohibited
		1	X	Setting prohibited
	1	0	0	Setting prohibited
			1	Complementary PWM mode 1 (transmit at crest)*3
		1	0	Complementary PWM mode 2 (transmit at trough)*3
			1	Complementary PWM mode 3 (transmit at crest and trough)*3

[Legend]
X: Don't care

Note 1. PWM mode 2 cannot be set for channels 3 and 4.

Note 2. Phase counting mode cannot be set for channels 0, 3, and 4.

Note 3. Reset synchronous PWM mode, complementary PWM mode can only be set for channel 3. When channel 3 is set to reset synchronous PWM mode or complementary PWM mode, the channel 4 settings become ineffective and automatically conform to the channel 3 settings. However, do not set channel 4 to reset synchronous PWM mode or complementary PWM mode. Reset synchronous PWM mode and complementary PWM mode cannot be set for channels 0, 1, and 2.

10.3.3 Timer I/O Control Register (TIOR)

The TIOR registers are 8-bit readable/writable registers that control the TGR registers. This module has a total of eight TIOR registers, two each for channels 0, 3, and 4, one each for channels 1 and 2.

TIOR should be set while TMDR is set in normal operation, PWM mode, or phase counting mode.

The initial output specified by TIOR is valid when the counter is stopped (the CST bit in TSTR is cleared to 0). Note also that, in PWM mode 2, the output at the point at which the counter is cleared to 0 is specified.

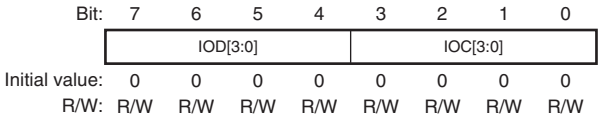
When TGRC or TGRD is designated for buffer operation, this setting is invalid and the register operates as a buffer register.

- TIORH_0, TIOR_1, TIOR_2, TIORH_3, TIORH_4

Bit:	7	6	5	4	3	2	1	0
	IOB[3:0]				IOA[3:0]			
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	IOB[3:0]	0000	R/W	I/O Control B0 to B3 Specify the function of TGRB. See the following tables. TIORH_0: Table 10.11 TIOR_1: Table 10.13 TIOR_2: Table 10.14 TIORH_3: Table 10.15 TIORH_4: Table 10.17
3 to 0	IOA[3:0]	0000	R/W	I/O Control A0 to A3 Specify the function of TGRA. See the following tables. TIORH_0: Table 10.19 TIOR_1: Table 10.21 TIOR_2: Table 10.22 TIORH_3: Table 10.23 TIORH_4: Table 10.25

- TIORL_0, TIORL_3, TIORL_4



Bit	Bit Name	Initial Value	R/W	Description
7 to 4	IOD[3:0]	0000	R/W	I/O Control D0 to D3 Specify the function of TGRD. See the following tables. TIORL_0: Table 10.12 TIORL_3: Table 10.16 TIORL_4: Table 10.18
3 to 0	IOC[3:0]	0000	R/W	I/O Control C0 to C3 Specify the function of TGRC. See the following tables. TIORL_0: Table 10.20 TIORL_3: Table 10.24 TIORL_4: Table 10.26

Table 10.11 TIORH_0 (Channel 0)

Bit 7 IOB3	Bit 6 IOB2	Bit 5 IOB1	Bit 4 IOB0	Description	
				TGRB_0 Function	TIOC0B Pin Function
0	0	0	0	Output compare register	Output retained*
			1		Initial output is 0 0 output at compare match
		1	0		Initial output is 0 1 output at compare match
			1		Initial output is 0 Toggle output at compare match
	1	0	0		Output retained
			1		Initial output is 1 0 output at compare match
		1	0		Initial output is 1 1 output at compare match
			1		Initial output is 1 Toggle output at compare match
1	0	0	0	Input capture register	Input capture at rising edge
			1		Input capture at falling edge
		1	X		Input capture at both edges
	1	X	X		Capture input source is channel 1/count clock Input capture at TCNT_1 count-up/count-down

[Legend]
X: Don't care
Note: * After power-on reset, 0 is output until TIOR is set.

Table 10.12 TIORL_0 (Channel 0)

Bit 7 IOD3	Bit 6 IOD2	Bit 5 IOD1	Bit 4 IOD0	Description

X: Don't care
Note 1. After power-on reset, 0 is output until TIOR is set.
Note 2. When the BFA bit in TMDR_4 is set to 1 and TGRC_4 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

10.3.4 Timer Interrupt Enable Register (TIER)

The TIER registers are 8-bit readable/writable registers that control enabling or disabling of interrupt requests for each channel. This module has six TIER registers, two for channel 0 and one each for channels 1 to 4.

- TIER_0, TIER_1, TIER_2, TIER_3, TIER_4

Bit:	7	6	5	4	3	2	1	0
	TTGE	TTGE2	TCIEU	TCIEV	TGIED	TGIEC	TGIEB	TGIEA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TTGE	0	R/W	A/D Conversion Start Request Enable Enables or disables generation of A/D conversion start requests by TGRA input capture/compare match. 0: A/D converter start request generation disabled 1: A/D converter start request generation enabled
6	TTGE2	0	R/W	A/D Conversion Start Request Enable 2 Enables or disables generation of A/D conversion start requests by TCNT_4 underflow (trough) in complementary PWM mode. In channels 0 to 3, bit 6 is reserved. It is always read as 0 and the write value should always be 0. 0: A/D conversion start request generation by TCNT_4 underflow (trough) disabled 1: A/D conversion start request generation by TCNT_4 underflow (trough) enabled
5	TCIEU	0	R/W	Underflow Interrupt Enable Enables or disables interrupt requests (TCIU) by the TCFU flag when the TCFU flag in TSR is set to 1 in channels 1 and 2. In channels 0, 3, and 4, bit 5 is reserved. It is always read as 0 and the write value should always be 0. 0: Interrupt requests (TCIU) by TCFU disabled 1: Interrupt requests (TCIU) by TCFU enabled
4	TCIEV	0	R/W	Overflow Interrupt Enable Enables or disables interrupt requests (TCIV) by the TCFV flag when the TCFV flag in TSR is set to 1. 0: Interrupt requests (TCIV) by TCFV disabled 1: Interrupt requests (TCIV) by TCFV enabled
3	TGIED	0	R/W	TGR Interrupt Enable D Enables or disables interrupt requests (TGID) by the TGFD bit when the TGFD bit in TSR is set to 1 in channels 0, 3, and 4. In channels 1 and 2, bit 3 is reserved. It is always read as 0 and the write value should always be 0. 0: Interrupt requests (TGID) by TGFD bit disabled 1: Interrupt requests (TGID) by TGFD bit enabled
2	TGIEC	0	R/W	TGR Interrupt Enable C Enables or disables interrupt requests (TGIC) by the TGFC bit when the TGFC bit in TSR is set to 1 in channels 0, 3, and 4. In channels 1 and 2, bit 2 is reserved. It is always read as 0 and the write value should always be 0. 0: Interrupt requests (TGIC) by TGFC bit disabled 1: Interrupt requests (TGIC) by TGFC bit enabled
1	TGIEB	0	R/W	TGR Interrupt Enable B Enables or disables interrupt requests (TGIB) by the TGFB bit when the TGFB bit in TSR is set to 1. 0: Interrupt requests (TGIB) by TGFB bit disabled 1: Interrupt requests (TGIB) by TGFB bit enabled

Bit	Bit Name	Initial Value	R/W	Description
0	TGIEA	0	R/W	TGR Interrupt Enable A Enables or disables interrupt requests (TGIA) by the TGFA bit when the TGFA bit in TSR is set to 1. 0: Interrupt requests (TGIA) by TGFA bit disabled 1: Interrupt requests (TGIA) by TGFA bit enabled

- TIER2_0

Bit:	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TTGE2	0	R/W	A/D Converter Start Request Enable 2 Enables or disables generation of A/D converter start requests by compare match between TCNT_0 and TGRE_0. 0: A/D converter start request generation by compare match between TCNT_0 and TGRE_0 disabled 1: A/D converter start request generation by compare match between TCNT_0 and TGRE_0 enabled
6 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	TGIEF	0	R/W	TGR Interrupt Enable F Enables or disables interrupt requests by compare match between TCNT_0 and TGRF_0. 0: Interrupt requests (TGIF) by TGFE bit disabled 1: Interrupt requests (TGIF) by TGFE bit enabled
0	TGIEE	0	R/W	TGR Interrupt Enable E Enables or disables interrupt requests by compare match between TCNT_0 and TGRE_0. 0: Interrupt requests (TGIE) by TGEE bit disabled 1: Interrupt requests (TGIE) by TGEE bit enabled

10.3.5 Timer Status Register (TSR)

The TSR registers are 8-bit readable/writable registers that indicate the status of each channel. This module has six TSR registers, two for channel 0 and one each for channels 1 to 4.

- TSR_0, TSR_1, TSR_2, TSR_3, TSR_4

Bit:	7	6	5	4	3	2	1	0
	TCFD	-	TCFU	TCFV	TGFD	TGFC	TGFB	TGFA
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R/(W)*1	R/(W)*1	R/(W)*1	R/(W)*1	R/(W)*1	R/(W)*1

Note: 1. Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

Bit	Bit Name	Initial Value	R/W	Description
7	TCFD	1	R	Count Direction Flag Status flag that shows the direction in which TCNT counts in channels 1 to 4. In channel 0, bit 7 is reserved. It is always read as 1 and the write value should always be 1. 0: TCNT counts down 1: TCNT counts up
6	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
5	TCFU	0	R/(W)*1	Underflow Flag Status flag that indicates that TCNT underflow has occurred when channels 1 and 2 are set to phase counting mode. Only 0 can be written, for flag clearing. In channels 0, 3, and 4, bit 5 is reserved. It is always read as 0 and the write value should always be 0. [Clearing condition] • When 0 is written to TCFU after reading TCFU = 1*2 [Setting condition] • When the TCNT value underflows (changes from H'0000 to H'FFFF)
4	TCFV	0	R/(W)*1	Overflow Flag Status flag that indicates that TCNT overflow has occurred. Only 0 can be written, for flag clearing. [Clearing condition] • When 0 is written to TCFV after reading TCFV = 1*2 [Setting condition] • When the TCNT value overflows (changes from H'FFFF to H'0000) In channel 4, when the TCNT_4 value underflows (changes from H'0001 to H'0000) in complementary PWM mode, this flag is also set.
3	TGFD	0	R/(W)*1	Input Capture/Output Compare Flag D Status flag that indicates the occurrence of TGRD input capture or compare match in channels 0, 3, and 4. Only 0 can be written, for flag clearing. In channels 1 and 2, bit 3 is reserved. It is always read as 0 and the write value should always be 0. [Clearing condition] • When 0 is written to TGFD after reading TGFD = 1*2 [Setting conditions] • When TCNT = TGRD and TGRD is functioning as output compare register • When TCNT value is transferred to TGRD by input capture signal and TGRD is functioning as input capture register

Bit	Bit Name	Initial Value	R/W	Description
2	TGFC	0	R/(W)*1	Input Capture/Output Compare Flag C Status flag that indicates the occurrence of TGRC input capture or compare match in channels 0, 3, and 4. Only 0 can be written, for flag clearing. In channels 1 and 2, bit 2 is reserved. It is always read as 0 and the write value should always be 0. [Clearing condition] • When 0 is written to TGFC after reading TGFC = 1*2 [Setting conditions] • When TCNT = TGRC and TGRC is functioning as output compare register • When TCNT value is transferred to TGRC by input capture signal and TGRC is functioning as input capture register
1	TGFB	0	R/(W)*1	Input Capture/Output Compare Flag B Status flag that indicates the occurrence of TGRB input capture or compare match. Only 0 can be written, for flag clearing. [Clearing condition] • When 0 is written to TGFB after reading TGFB = 1*2 [Setting conditions] • When TCNT = TGRB and TGRB is functioning as output compare register • When TCNT value is transferred to TGRB by input capture signal and TGRB is functioning as input capture register
0	TGFA	0	R/(W)*1	Input Capture/Output Compare Flag A Status flag that indicates the occurrence of TGRA input capture or compare match. Only 0 can be written, for flag clearing. [Clearing conditions] • When the direct memory access controller is activated by TGIA interrupt • When 0 is written to TGFA after reading TGFA = 1*2 [Setting conditions] • When TCNT = TGRA and TGRA is functioning as output compare register • When TCNT value is transferred to TGRA by input capture signal and TGRA is functioning as input capture register

Note 1. Writing 0 to this bit after reading it as 1 clears the flag.
Note 2. If the next flag is set before TGFA is cleared to 0 after reading TGFA = 1, TGFA remains 1 even when 0 is written to. In this case, read TGFA = 1 again to clear TGFA to 0.

- TSR2_0

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	TGFF	TGFE
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/(W)*1	R/(W)*1

Note: 1. Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
5 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	TGFF	0	R/(W)*1	Compare Match Flag F Status flag that indicates the occurrence of compare match between TCNT_0 and TGRF_0. [Clearing condition] • When 0 is written to TGFF after reading TGFF = 1*2 [Setting condition] • When TCNT_0 = TGRF_0 and TGRF_0 is functioning as compare register
0	TGFE	0	R/(W)*1	Compare Match Flag E Status flag that indicates the occurrence of compare match between TCNT_0 and TGRE_0. [Clearing condition] • When 0 is written to TGFE after reading TGFE = 1*2 [Setting condition] • When TCNT_0 = TGRE_0 and TGRE_0 is functioning as compare register

Note 1. Writing 0 to this bit after reading it as 1 clears the flag.
Note 2. If the next flag is set before TGFA is cleared to 0 after reading TGFA = 1, TGFA remains 1 even when 0 is written to. In this case, read TGFA = 1 again to clear TGFA to 0.

10.3.6 Timer Buffer Operation Transfer Mode Register (TBTM)

The TBTM registers are 8-bit readable/writable registers that specify the timing for transferring data from the buffer register to the timer general register in PWM mode. This module has three TBTM registers, one each for channels 0, 3, and 4.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	TTSE	TTSB	TTSA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TTSE	0	R/W	Timing Select E Specifies the timing for transferring data from TGRF_0 to TGRE_0 when they are used together for buffer operation. In channels 3 and 4, bit 2 is reserved. It is always read as 0 and the write value should always be 0. Do not set this bit to 1 when PWM mode is not selected in channel 0. 0: When compare match E occurs in channel 0 1: When TCNT_0 is cleared
1	TTSB	0	R/W	Timing Select B Specifies the timing for transferring data from TGRD to TGRB in each channel when they are used together for buffer operation. Do not set this bit to 1 when PWM mode is not selected in any channels. 0: When compare match B occurs in each channel 1: When TCNT is cleared in each channel
0	TTSA	0	R/W	Timing Select A Specifies the timing for transferring data from TGRC to TGRA in each channel when they are used together for buffer operation. Do not set this bit to 1 when PWM mode is not selected in any channels. 0: When compare match A occurs in each channel 1: When TCNT is cleared in each channel

10.3.7 Timer Input Capture Control Register (TICCR)

TICCR is an 8-bit readable/writable register that specifies input capture conditions when TCNT_1 and TCNT_2 are cascaded. This module has one TICCR in channel 1.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	I2BE	I2AE	I1BE	I1AE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	I2BE	0	R/W	Input Capture Enable Specifies whether to include the TIOC2B pin in the TGRB_1 input capture conditions. 0: Does not include the TIOC2B pin in the TGRB_1 input capture conditions 1: Includes the TIOC2B pin in the TGRB_1 input capture conditions
2	I2AE	0	R/W	Input Capture Enable Specifies whether to include the TIOC2A pin in the TGRA_1 input capture conditions. 0: Does not include the TIOC2A pin in the TGRA_1 input capture conditions 1: Includes the TIOC2A pin in the TGRA_1 input capture conditions
1	I1BE	0	R/W	Input Capture Enable Specifies whether to include the TIOC1B pin in the TGRB_2 input capture conditions. 0: Does not include the TIOC1B pin in the TGRB_2 input capture conditions 1: Includes the TIOC1B pin in the TGRB_2 input capture conditions
0	I1AE	0	R/W	Input Capture Enable Specifies whether to include the TIOC1A pin in the TGRA_2 input capture conditions. 0: Does not include the TIOC1A pin in the TGRA_2 input capture conditions 1: Includes the TIOC1A pin in the TGRA_2 input capture conditions

10.3.8 Timer A/D Converter Start Request Control Register (TADCR)

TADCR is a 16-bit readable/writable register that enables or disables A/D converter start requests and specifies whether to link A/D converter start requests with interrupt skipping operation. This module has one TADCR in channel 4.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BF[1:0]		-	-	-	-	-	-	UT4AE	DT4AE	UT4BE	DT4BE	ITA3AE	ITA4VE	ITB3AE	ITB4VE
Initial value:	0	0	0	0	0	0	0	0	0	0*	0	0*	0*	0*	0*	0*
R/W:	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	BF[1:0]	00	R/W	TADCOBRA_4/TADCOBRB_4 Transfer Timing Select Select the timing for transferring data from TADCOBRA_4 and TADCOBRB_4 to TADCORA_4 and TADCORB_4. For details, see Table 10.27.
13 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	UT4AE	0	R/W	Up-Count TRG4AN Enable Enables or disables A/D converter start requests (TRG4AN) during TCNT_4 up-count operation. 0: A/D converter start requests (TRG4AN) disabled during TCNT_4 up-count operation 1: A/D converter start requests (TRG4AN) enabled during TCNT_4 up-count operation
6	DT4AE	0*	R/W	Down-Count TRG4AN Enable Enables or disables A/D converter start requests (TRG4AN) during TCNT_4 down-count operation. 0: A/D converter start requests (TRG4AN) disabled during TCNT_4 down-count operation 1: A/D converter start requests (TRG4AN) enabled during TCNT_4 down-count operation
5	UT4BE	0	R/W	Up-Count TRG4BN Enable Enables or disables A/D converter start requests (TRG4BN) during TCNT_4 up-count operation. 0: A/D converter start requests (TRG4BN) disabled during TCNT_4 up-count operation 1: A/D converter start requests (TRG4BN) enabled during TCNT_4 up-count operation
4	DT4BE	0*	R/W	Down-Count TRG4BN Enable Enables or disables A/D converter start requests (TRG4BN) during TCNT_4 down-count operation. 0: A/D converter start requests (TRG4BN) disabled during TCNT_4 down-count operation 1: A/D converter start requests (TRG4BN) enabled during TCNT_4 down-count operation
3	ITA3AE	0*	R/W	TGIA_3 Interrupt Skipping Link Enable Select whether to link A/D converter start requests (TRG4AN) with TGIA_3 interrupt skipping operation. 0: Does not link with TGIA_3 interrupt skipping 1: Links with TGIA_3 interrupt skipping
2	ITA4VE	0*	R/W	TCIV_4 Interrupt Skipping Link Enable Select whether to link A/D converter start requests (TRG4AN) with TCIV_4 interrupt skipping operation. 0: Does not link with TCIV_4 interrupt skipping 1: Links with TCIV_4 interrupt skipping

Bit	Bit Name	Initial Value	R/W	Description
1	ITB3AE	0*	R/W	TGIA_3 Interrupt Skipping Link Enable Select whether to link A/D converter start requests (TRG4BN) with TGIA_3 interrupt skipping operation. 0: Does not link with TGIA_3 interrupt skipping 1: Links with TGIA_3 interrupt skipping
0	ITB4VE	0*	R/W	TCIV_4 Interrupt Skipping Link Enable Select whether to link A/D converter start requests (TRG4BN) with TCIV_4 interrupt skipping operation. 0: Does not link with TCIV_4 interrupt skipping 1: Links with TCIV_4 interrupt skipping

Note 1. TADCR must not be accessed in eight bits; it should always be accessed in 16 bits.
Note 2. When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), do not link A/D converter start requests with interrupt skipping operation (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).
Note 3. If link with interrupt skipping is enabled while interrupt skipping is disabled, A/D converter start requests will not be issued.
Note: * Do not set to 1 when complementary PWM mode is not selected.

Table 10.27 Setting of Transfer Timing by Bits BF1 and BF0

Bit 7	Bit 6	
BF1	BF0	Description
0	0	Does not transfer data from the cycle set buffer register to the cycle set register.
0	1	Transfers data from the cycle set buffer register to the cycle set register at the crest of the TCNT_4 count.*1
1	0	Transfers data from the cycle set buffer register to the cycle set register at the trough of the TCNT_4 count.*2
1	1	Transfers data from the cycle set buffer register to the cycle set register at the crest and trough of the TCNT_4 count.*2

Note 1. Data is transferred from the cycle set buffer register to the cycle set register when the crest of the TCNT_4 count is reached in complementary PWM mode, when compare match occurs between TCNT_3 and TGRA_3 in reset-synchronized PWM mode, or when compare match occurs between TCNT_4 and TGRA_4 in PWM mode 1 or normal operation mode.
Note 2. These settings are prohibited when complementary PWM mode is not selected.

10.3.9 Timer A/D Converter Start Request Cycle Set Registers (TADCORA_4 and TADCORB_4)

TADCORA_4 and TADCORB_4 are 16-bit readable/writable registers. When the TCNT_4 count reaches the value in TADCORA_4 or TADCORB_4, a corresponding A/D converter start request will be issued.

TADCORA_4 and TADCORB_4 are initialized to H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: TADCORA_4 and TADCORB_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

10.3.10 Timer A/D Converter Start Request Cycle Set Buffer Registers (TADCOBRA_4 and TADCOBRB_4)

TADCOBRA_4 and TADCOBRB_4 are 16-bit readable/writable registers. When the crest or trough of the TCNT_4 count is reached, these register values are transferred to TADCORA_4 and TADCORB_4, respectively.

TADCOBRA_4 and TADCOBRB_4 are initialized to H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: TADCOBRA_4 and TADCOBRB_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

10.3.11 Timer Counter (TCNT)

The TCNT counters are 16-bit readable/writable counters. This module has five TCNT counters, one each for channels 0 to 4.

The TCNT counters must not be accessed in eight bits; they should always be accessed in 16 bits.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: The TCNT counters must not be accessed in eight bits; they should always be accessed in 16 bits.

10.3.12 Timer General Register (TGR)

The TGR registers are 16-bit readable/writable registers. This module has eighteen TGR registers, six for channel 0, two each for channels 1 and 2, four each for channels 3 and 4.

TGRA, TGRB, TGRC, and TGRD function as either output compare or input capture registers. TGRC and TGRD for channels 0, 3, and 4 can also be designated for operation as buffer registers. TGR buffer register combinations are TGRA and TGRC, and TGRB and TGRD.

TGRE_0 and TGRF_0 function as compare registers. When the TCNT_0 count matches the TGRE_0 value, an A/D converter start request can be issued. TGRF can also be designated for operation as a buffer register. TGR buffer register combination is TGRE and TGRF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: The TGR registers must not be accessed in eight bits; they should always be accessed in 16 bits.
TGR registers are initialized to H'FFFF.

10.3.13 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects operation/stoppage of TCNT for channels 0 to 4.

When setting the operating mode in TMDR or setting the count clock in TCR, first stop the TCNT counter.

Bit:	7	6	5	4	3	2	1	0
	CST4	CST3	-	-	-	CST2	CST1	CST0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CST4	0	R/W	Counter Start 4 and 3 These bits select operation or stoppage for TCNT. If 0 is written to the CST bit during operation with the TIOC pin designated for output, the counter stops but the TIOC pin output compare output level is retained. If TIOR is written to when the CST bit is cleared to 0, the pin output level will be changed to the set initial output value. 0: TCNT_4 and TCNT_3 count operation is stopped 1: TCNT_4 and TCNT_3 performs count operation
6	CST3	0	R/W	
5 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CST2	0	R/W	Counter Start 2 to 0 These bits select operation or stoppage for TCNT. If 0 is written to the CST bit during operation with the TIOC pin designated for output, the counter stops but the TIOC pin output compare output level is retained. If TIOR is written to when the CST bit is cleared to 0, the pin output level will be changed to the set initial output value. 0: TCNT_2 to TCNT_0 count operation is stopped 1: TCNT_2 to TCNT_0 performs count operation
1	CST1	0	R/W	
0	CST0	0	R/W	

10.3.14 Timer Synchronous Register (TSYR)

TSYR is an 8-bit readable/writable register that selects independent operation or synchronous operation for the channel 0 to 4 TCNT counters. A channel performs synchronous operation when the corresponding bit in TSYR is set to 1.

Bit:	7	6	5	4	3	2	1	0
	SYNC4	SYNC3	-	-	-	SYNC2	SYNC1	SYNC0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	SYNC4	0	R/W	Timer Synchronous operation 4 and 3 These bits are used to select whether operation is independent of or synchronized with other channels. When synchronous operation is selected, the TCNT synchronous presetting of multiple channels, and synchronous clearing by counter clearing on another channel, are possible. To set synchronous operation, the SYNC bits for at least two channels must be set to 1. To set synchronous clearing, in addition to the SYNC bit , the TCNT clearing source must also be set by means of bits CCLR0 to CCLR2 in TCR. 0: TCNT_4 and TCNT_3 operate independently (TCNT presetting/clearing is unrelated to other channels) 1: TCNT_4 and TCNT_3 performs synchronous operation TCNT synchronous presetting/synchronous clearing is possible
6	SYNC3	0	R/W	
5 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	SYNC2	0	R/W	Timer Synchronous operation 2 to 0 These bits are used to select whether operation is independent of or synchronized with other channels. When synchronous operation is selected, the TCNT synchronous presetting of multiple channels, and synchronous clearing by counter clearing on another channel, are possible. To set synchronous operation, the SYNC bits for at least two channels must be set to 1. To set synchronous clearing, in addition to the SYNC bit, the TCNT clearing source must also be set by means of bits CCLR0 to CCLR2 in TCR. 0: TCNT_2 to TCNT_0 operates independently (TCNT presetting /clearing is unrelated to other channels) 1: TCNT_2 to TCNT_0 performs synchronous operation TCNT synchronous presetting/synchronous clearing is possible
1	SYNC1	0	R/W	
0	SYNC0	0	R/W	

10.3.15 Timer Read/Write Enable Register (TRWER)

TRWER is an 8-bit readable/writable register that enables or disables access to the registers and counters which have write-protection capability against accidental modification in channels 3 and 4.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	RWE
Initial value:	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RWE	1	R/W	Read/Write Enable Enables or disables access to the registers which have write-protection capability against accidental modification. 0: Disables read/write access to the registers 1: Enables read/write access to the registers [Clearing condition] • When 0 is written to the RWE bit after reading RWE = 1

- Registers and counters having write-protection capability against accidental modification
  22 registers: TCR_3, TCR_4, TMDR_3, TMDR_4, TIORH_3, TIORH_4, TIORL_3, TIORL_4, TIER_3, TIER_4, TGRA_3, TGRA_4, TGRB_3, TGRB_4, TOER, TOCR1, TOCR2, TGCR, TCDR, TDDR, TCNT_3, and TCNT_4.

10.3.16 Timer Output Master Enable Register (TOER)

TOER is an 8-bit readable/writable register that enables/disables output settings for output pins TIOC4D, TIOC4C, TIOC3D, TIOC4B, TIOC4A, and TIOC3B. These pins do not output correctly if the TOER bits have not been set. Set TOER of CH3 and CH4 prior to setting TIOR of CH3 and CH4.

Make settings of the TOER while counting by the TCNT registers of channels 3 and 4 is stopped.

Bit:	7	6	5	4	3	2	1	0
	-	-	OE4D	OE4C	OE3D	OE4B	OE4A	OE3B
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
5	OE4D	0	R/W	Master Enable TIOC4D This bit enables/disables the TIOC4D pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled
4	OE4C	0	R/W	Master Enable TIOC4C This bit enables/disables the TIOC4C pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled
3	OE3D	0	R/W	Master Enable TIOC3D This bit enables/disables the TIOC3D pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled
2	OE4B	0	R/W	Master Enable TIOC4B This bit enables/disables the TIOC4B pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled
1	OE4A	0	R/W	Master Enable TIOC4A This bit enables/disables the TIOC4A pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled
0	OE3B	0	R/W	Master Enable TIOC3B This bit enables/disables the TIOC3B pin output for this module. 0: Output for this module is disabled (inactive level)* 1: Output for this module is enabled

Note: * The inactive level is determined by the settings in timer output control registers 1 and 2 (TOCR1 and TOCR2). For details, refer to section 10.3.17, Timer Output Control Register 1 (TOCR1), and section 10.3.18, Timer Output Control Register 2 (TOCR2). Set these bits to 1 to enable output for this module in other than complementary PWM or reset-synchronized PWM mode. When these bits are set to 0, low level is output.

10.3.17 Timer Output Control Register 1 (TOCR1)

TOCR1 is an 8-bit readable/writable register that enables/disables PWM synchronized toggle output in complementary PWM mode/reset synchronized PWM mode, and controls output level inversion of PWM output.

Bit:	7	6	5	4	3	2	1	0
	-	PSYE	-	-	TOCL	TOCS	OLSN	OLSP
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R	R/(W)*3	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	PSYE	0	R/W	PWM Synchronous Output Enable This bit selects the enable/disable of toggle output synchronized with the PWM period. 0: Toggle output is disabled 1: Toggle output is enabled
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	TOCL	0	R/(W)*3	TOC Register Write Protection*1 This bit selects the enable/disable of write access to the TOCS, OLSN, and OLSP bits in TOCR1. 0: Write access to the TOCS, OLSN, and OLSP bits is enabled 1: Write access to the TOCS, OLSN, and OLSP bits is disabled
2	TOCS	0	R/W	TOC Select This bit selects either the TOCR1 or TOCR2 setting to be used for the output level in complementary PWM mode and reset-synchronized PWM mode. 0: TOCR1 setting is selected 1: TOCR2 setting is selected
1	OLSN	0	R/W	Output Level Select N*2*4 This bit selects the negative phase output level in reset-synchronized PWM mode/complementary PWM mode. See Table 10.28.
0	OLSP	0	R/W	Output Level Select P*2 This bit selects the positive phase output level in reset-synchronized PWM mode/complementary PWM mode. See Table 10.29.

Note 1. Setting the TOCL bit to 1 prevents accidental modification when the CPU goes out of control.
Note 2. Clearing the TOCS bit to 0 makes this bit setting valid.
Note 3. After power-on reset, 1 can be written only once. After 1 has been written, 0 cannot be written.
Note 4. If the dead-time is not generated, the negative-phase output will be the exact inverse of the positive-phase output. Furthermore, set OLSP and OLSN to the same value.

Table 10.28 Output Level Select Function

Bit 1	Function			
			Compare Match Output	
OLSN	Initial Output	Active Level	Up Count	Down Count
0	High level	Low level	High level	Low level
1	Low level	High level	Low level	High level

Note: The negative phase waveform initial output value changes to active level after elapse of the dead time after count start.

Table 10.29 Output Level Select Function

Bit 0	Function			
			Compare Match Output	
OLSP	Initial Output	Active Level	Up Count	Down Count
0	High level	Low level	Low level	High level
1	Low level	High level	High level	Low level

Figure 10.2 shows an example of complementary PWM mode output (1 phase) when OLSN = 1, OLSP = 1.

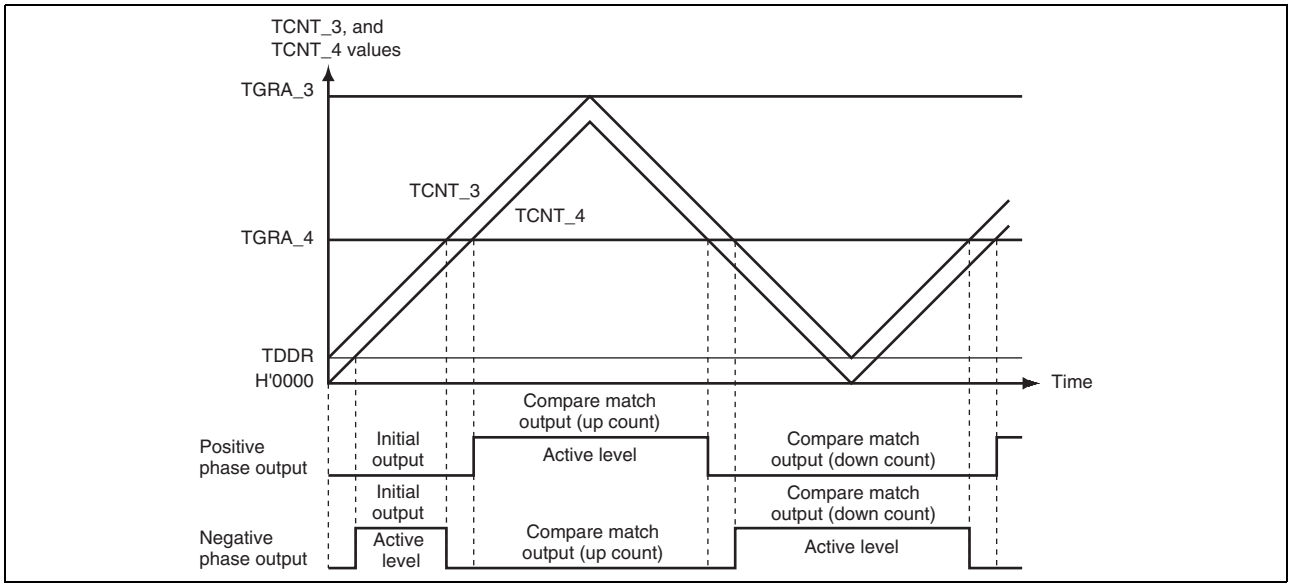

Figure 10.2 Complementary PWM Mode Output Level Example

10.3.18 Timer Output Control Register 2 (TOCR2)

TOCR2 is an 8-bit readable/writable register that controls output level inversion of PWM output in complementary PWM mode and reset-synchronized PWM mode.

Bit:	7	6	5	4	3	2	1	0
	BF[1:0]		OLS3N	OLS3P	OLS2N	OLS2P	OLS1N	OLS1P
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7, 6	BF[1:0]	00	R/W	TOLBR Buffer Transfer Timing Select These bits select the timing for transferring data from TOLBR to TOCR2. For details, see Table 10.30.
5	OLS3N	0	R/W	Output Level Select 3N* This bit selects the output level on TIOC4D in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.31.
4	OLS3P	0	R/W	Output Level Select 3P* This bit selects the output level on TIOC4B in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.32.
3	OLS2N	0	R/W	Output Level Select 2N* This bit selects the output level on TIOC4C in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.33.
2	OLS2P	0	R/W	Output Level Select 2P* This bit selects the output level on TIOC4A in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.34.
1	OLS1N	0	R/W	Output Level Select 1N* This bit selects the output level on TIOC3D in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.35.
0	OLS1P	0	R/W	Output Level Select 1P* This bit selects the output level on TIOC3B in reset-synchronized PWM mode/ complementary PWM mode. See Table 10.36.

Note: * Setting the TOCS bit in TOCR1 to 1 makes this bit setting valid.
If the dead-time is not generated, the negative-phase output will be the exact inverse of the positive-phase output. Furthermore, set OLSiP and OLSiN (i = 1, 2, 3) to the same value.

Table 10.30 Setting of Bits BF1 and BF0

Bit 7	Bit 6	Description	
BF1	BF0	Complementary PWM Mode	Reset-Synchronized PWM Mode
0	0	Does not transfer data from the buffer register (TOLBR) to TOCR2.	Does not transfer data from the buffer register (TOLBR) to TOCR2.
0	1	Transfers data from the buffer register (TOLBR) to TOCR2 at the crest of the TCNT_4 count.	Transfers data from the buffer register (TOLBR) to TOCR2 when TCNT_3/TCNT_4 is cleared
1	0	Transfers data from the buffer register (TOLBR) to TOCR2 at the trough of the TCNT_4 count.	Setting prohibited
1	1	Transfers data from the buffer register (TOLBR) to TOCR2 at the crest and trough of the TCNT_4 count.	Setting prohibited

10.3.19 Timer Output Level Buffer Register (TOLBR)

TOLBR is an 8-bit readable/writable register that functions as a buffer for TOCR2 and specifies the PWM output level in complementary PWM mode and reset-synchronized PWM mode.

Bit:	7	6	5	4	3	2	1	0
	-	-	OLS3N	OLS3P	OLS2N	OLS2P	OLS1N	OLS1P
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	OLS3N	0	R/W	Specifies the buffer value to be transferred to the OLS3N bit in TOCR2.
4	OLS3P	0	R/W	Specifies the buffer value to be transferred to the OLS3P bit in TOCR2.
3	OLS2N	0	R/W	Specifies the buffer value to be transferred to the OLS2N bit in TOCR2.
2	OLS2P	0	R/W	Specifies the buffer value to be transferred to the OLS2P bit in TOCR2.
1	OLS1N	0	R/W	Specifies the buffer value to be transferred to the OLS1N bit in TOCR2.
0	OLS1P	0	R/W	Specifies the buffer value to be transferred to the OLS1P bit in TOCR2.

Figure 10.3 shows an example of the PWM output level setting procedure in buffer operation.

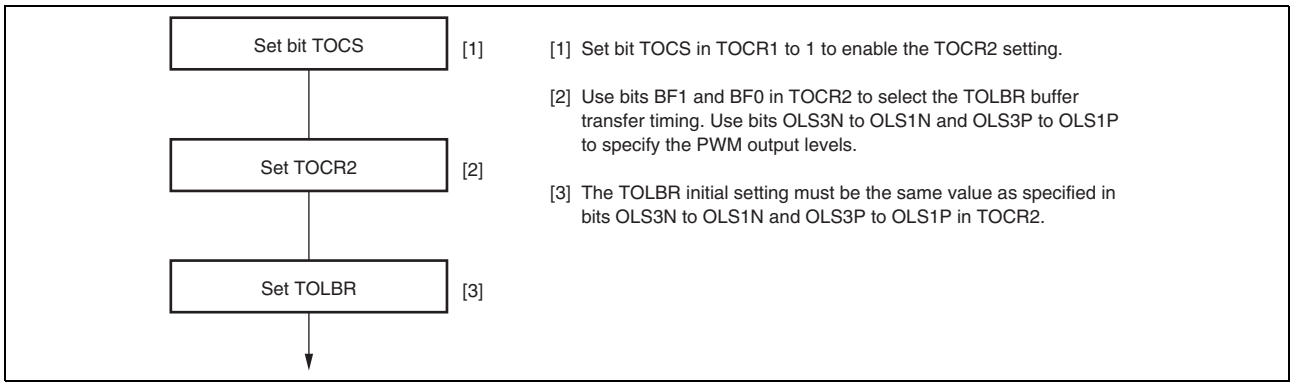

Figure 10.3 PWM Output Level Setting Procedure in Buffer Operation

10.3.20 Timer Gate Control Register (TGCR)

TGCR is an 8-bit readable/writable register that controls the waveform output necessary for brushless DC motor control in reset-synchronized PWM mode/complementary PWM mode. These register settings are ineffective for anything other than complementary PWM mode/reset-synchronized PWM mode.

Bit:	7	6	5	4	3	2	1	0
	-	BDC	N	P	FB	WF	VF	UF
Initial value:	1	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
6	BDC	0	R/W	Brushless DC Motor This bit selects whether to make the functions of this register (TGCR) effective or ineffective. 0: Ordinary output 1: Functions of this register are made effective
5	N	0	R/W	Negative Phase Output (N) Control This bit selects whether the level output or the reset-synchronized PWM/ complementary PWM output while the reverse pins (TIOC3D, TIOC4C, and TIOC4D) are output. 0: Level output 1: Reset synchronized PWM/complementary PWM output
4	P	0	R/W	Positive Phase Output (P) Control This bit selects whether the level output or the reset-synchronized PWM/ complementary PWM output while the positive pins (TIOC3B, TIOC4A, and TIOC4B) are output. 0: Level output 1: Reset synchronized PWM/complementary PWM output
3	FB	0	R/W	External Feedback Signal Enable This bit selects whether the switching of the output of the positive/negative phase is carried out automatically with channel-0 TGRA, TGRB, TGRC input capture signals or by writing 0 or 1 to bits 2 to 0 in TGCR. 0: Output switching is external input (Input sources are channel 0 TGRA, TGRB, TGRC input capture signal) 1: Output switching is carried out by software (setting values of UF, VF, and WF in TGCR).
2	WF	0	R/W	Output Phase Switch 2 to 0 These bits set the positive phase/negative phase output phase on or off state. The setting of these bits is valid only when the FB bit in this register is set to 1. In this case, the setting of bits 2 to 0 is a substitute for external input. See Table 10.37.
1	VF	0	R/W	
0	UF	0	R/W	

Table 10.37 Output level Select Function

			Function					
Bit 2	**Bit 1**	**Bit 0**	**TIOC3B**	**TIOC4A**	**TIOC4B**	**TIOC3D**	**TIOC4C**	**TIOC4D**
WF	**VF**	**UF**	**U Phase**	**V Phase**	**W Phase**	**U Phase**	**V Phase**	**W Phase**
0	0	0	OFF	OFF	OFF	OFF	OFF	OFF
		1	ON	OFF	OFF	OFF	OFF	ON
	1	0	OFF	ON	OFF	ON	OFF	OFF
		1	OFF	ON	OFF	OFF	OFF	ON
1	0	0	OFF	OFF	ON	OFF	ON	OFF
		1	ON	OFF	OFF	OFF	ON	OFF
	1	0	OFF	OFF	ON	ON	OFF	OFF
		1	OFF	OFF	OFF	OFF	OFF	OFF

10.3.21 Timer Subcounter (TCNTS)

TCNTS is a 16-bit read-only counter that is used only in complementary PWM mode.

The initial value of TCNTS is H'0000.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note: Accessing the TCNTS in 8-bit units is prohibited. Always access in 16-bit units.

10.3.22 Timer Dead Time Data Register (TDDR)

TDDR is a 16-bit register, used only in complementary PWM mode that specifies the TCNT_3 and TCNT_4 counter offset values. In complementary PWM mode, when the TCNT_3 and TCNT_4 counters are cleared and then restarted, the TDDR register value is loaded into the TCNT_3 counter and the count operation starts.

The initial value of TDDR is H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Accessing the TDDR in 8-bit units is prohibited. Always access in 16-bit units.

10.3.23 Timer Cycle Data Register (TCDR)

TCDR is a 16-bit register used only in complementary PWM mode. Set half the PWM carrier cycle value (however, the value must also be at least twice the setting of TDDR plus 3) as the TCDR register value. This register is constantly compared with the TCNTS counter in complementary PWM mode, and when a match occurs, the TCNTS counter switches direction (decrement to increment).

The initial value of TCDR is H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Accessing the TCDR in 8-bit units is prohibited. Always access in 16-bit units.

10.3.24 Timer Cycle Buffer Register (TCBR)

TCBR is a 16-bit register used only in complementary PWM mode. It functions as a buffer register for the TCDR register. The TCBR register values are transferred to the TCDR register with the transfer timing set in the TMDR register. The initial value of TCBR is H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: Accessing the TCBR in 8-bit units is prohibited. Always access in 16-bit units.

10.3.25 Timer Interrupt Skipping Set Register (TITCR)

TITCR is an 8-bit readable/writable register that enables or disables interrupt skipping and specifies the interrupt skipping count. This module has one TITCR.

Bit:	7	6	5	4	3	2	1	0
	T3AEN	3ACOR[2:0]			T4VEN	4VCOR[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description
7	T3AEN	0	R/W	T3AEN Enables or disables TGIA_3 interrupt skipping. 0: TGIA_3 interrupt skipping disabled 1: TGIA_3 interrupt skipping enabled
6 to 4	3ACOR[2:0]	000	R/W	These bits specify the TGIA_3 interrupt skipping count within the range from 0 to 7.* For details, see Table 10.38.
3	T4VEN	0	R/W	T4VEN Enables or disables TCIV_4 interrupt skipping. 0: TCIV_4 interrupt skipping disabled 1: TCIV_4 interrupt skipping enabled
2 to 0	4VCOR[2:0]	000	R/W	These bits specify the TCIV_4 interrupt skipping count within the range from 0 to 7.* For details, see Table 10.39.

Note: * When 0 is specified for the interrupt skipping count, no interrupt skipping will be performed. Before changing the interrupt skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter (TITCNT).

Table 10.38 Setting of Interrupt Skipping Count by Bits 3ACOR2 to 3ACOR0

Bit 6	Bit 5	Bit 4	
3ACOR2	**3ACOR1**	**3ACOR0**	**Description**
0	0	0	Does not skip TGIA_3 interrupts.
0	0	1	Sets the TGIA_3 interrupt skipping count to 1.
0	1	0	Sets the TGIA_3 interrupt skipping count to 2.
0	1	1	Sets the TGIA_3 interrupt skipping count to 3.
1	0	0	Sets the TGIA_3 interrupt skipping count to 4.
1	0	1	Sets the TGIA_3 interrupt skipping count to 5.
1	1	0	Sets the TGIA_3 interrupt skipping count to 6.
1	1	1	Sets the TGIA_3 interrupt skipping count to 7.

Table 10.39 Setting of Interrupt Skipping Count by Bits 4VCOR2 to 4VCOR0

Bit 2	Bit 1	Bit 0	
4VCOR2	**4VCOR1**	**4VCOR0**	**Description**
0	0	0	Does not skip TCIV_4 interrupts.
0	0	1	Sets the TCIV_4 interrupt skipping count to 1.
0	1	0	Sets the TCIV_4 interrupt skipping count to 2.
0	1	1	Sets the TCIV_4 interrupt skipping count to 3.
1	0	0	Sets the TCIV_4 interrupt skipping count to 4.
1	0	1	Sets the TCIV_4 interrupt skipping count to 5.
1	1	0	Sets the TCIV_4 interrupt skipping count to 6.
1	1	1	Sets the TCIV_4 interrupt skipping count to 7.

10.3.26 Timer Interrupt Skipping Counter (TITCNT)

TITCNT is an 8-bit readable counter. This module has one TITCNT. TITCNT retains its value even after stopping the count operation of TCNT_3 and TCNT_4.

Bit:	7	6	5	4	3	2	1	0
	-	3ACNT[2:0]			-	4VCNT[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0.
6 to 4	3ACNT[2:0]	000	R	TGIA_3 Interrupt Counter While the T3AEN bit in TITCR is set to 1, the count in these bits is incremented every time a TGIA_3 interrupt occurs. [Clearing conditions] • When the 3ACNT2 to 3ACNT0 value in TITCNT matches the 3ACOR2 to 3ACOR0 value in TITCR • When the T3AEN bit in TITCR is cleared to 0 • When the 3ACOR2 to 3ACOR0 bits in TITCR are cleared to 0
3	—	0	R	Reserved This bit is always read as 0.
2 to 0	4VCNT[2:0]	000	R	TCIV_4 Interrupt Counter While the T4VEN bit in TITCR is set to 1, the count in these bits is incremented every time a TCIV_4 interrupt occurs. [Clearing conditions] • When the 4VCNT2 to 4VCNT0 value in TITCNT matches the 4VCOR2 to 4VCOR0 value in TITCR • When the T4VEN bit in TITCR is cleared to 0 • When the 4VCOR2 to 4VCOR0 bits in TITCR are cleared to 0

Note: To clear the TITCNT, clear the bits T3AEN and T4VEN in TITCR to 0.

10.3.27 Timer Buffer Transfer Set Register (TBTER)

TBTER is an 8-bit readable/writable register that enables or disables transfer from the buffer registers* used in complementary PWM mode to the temporary registers and specifies whether to link the transfer with interrupt skipping operation. This module has one TBTER.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	BTE[1:0]	
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	BTE[1:0]	00	R/W	These bits enable or disable transfer from the buffer registers* used in complementary PWM mode to the temporary registers and specify whether to link the transfer with interrupt skipping operation. For details, see Table 10.40.

Note: * Applicable buffer registers:
TGRC_3, TGRD_3, TGRC_4, TGRD_4, and TCBR

Table 10.40 Setting of Bits BTE1 and BTE0

Bit 1	Bit 0	
BTE1	**BTE0**	**Description**
0	0	Enables transfer from the buffer registers to the temporary registers*1 and does not link the transfer with interrupt skipping operation.
0	1	Disables transfer from the buffer registers to the temporary registers.
1	0	Links transfer from the buffer registers to the temporary registers with interrupt skipping operation.*2
1	1	Setting prohibited

Note 1. Data is transferred according to the MD3 to MD0 bit setting in TMDR. For details, refer to section 10.4.8, Complementary PWM Mode.

Note 2. When interrupt skipping is disabled (the T3AEN and T4VEN bits are cleared to 0 in the timer interrupt skipping set register (TITCR) or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0)), be sure to disable link of buffer transfer with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If link with interrupt skipping is enabled while interrupt skipping is disabled, buffer transfer will not be performed.

10.3.28 Timer Dead Time Enable Register (TDER)

TDER is an 8-bit readable/writable register that controls dead time generation in complementary PWM mode. This module has one TDER in channel 3. TDER must be modified only while TCNT stops.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	TDER
Initial value:	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R/(W)

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TDER	1	R/(W)	Dead Time Enable Specifies whether to generate dead time. 0: Does not generate dead time 1: Generates dead time* [Clearing condition] • When 0 is written to TDER after reading TDER = 1

Note: * TDDR must be set to 1 or a larger value.

10.3.29 Timer Waveform Control Register (TWCR)

TWCR is an 8-bit readable/writable register that controls the waveform when synchronous counter clearing occurs in TCNT_3 and TCNT_4 in complementary PWM mode and specifies whether to clear the counters at TGRA_3 compare match. The CCE bit and WRE bit in TWCR must be modified only while TCNT stops.

Bit:	7	6	5	4	3	2	1	0
	CCE	-	-	-	-	-	-	WRE
Initial value:	0*	0	0	0	0	0	0	0
R/W:	R/(W)	R	R	R	R	R	R	R/(W)

Bit	Bit Name	Initial Value	R/W	Description
7	CCE	0*	R/(W)	Compare Match Clear Enable Specifies whether to clear counters at TGRA_3 compare match in complementary PWM mode. 0: Does not clear counters at TGRA_3 compare match 1: Clears counters at TGRA_3 compare match [Setting condition] • When 1 is written to CCE after reading CCE = 0
6 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	WRE	0	R/(W)	Initial Output Suppression Enable Selects the waveform output when synchronous counter clearing occurs in complementary PWM mode. The initial output is suppressed only when synchronous clearing occurs within the Tb interval at the trough in complementary PWM mode. When synchronous clearing occurs outside this interval, the initial value specified in TOCR is output regardless of the WRE bit setting. The initial value is also output when synchronous clearing occurs in the Tb interval at the trough immediately after TCNT_3 and TCNT_4 start operation. For the Tb interval at the trough in complementary PWM mode, see Figure 10.40. 0: Outputs the initial value specified in TOCR 1: Suppresses initial output [Setting condition] • When 1 is written to WRE after reading WRE = 0

Note: * Do not set to 1 when complementary PWM mode 1 is not selected.

10.3.30 Bus Master Interface

The timer counters (TCNT), general registers (TGR), timer subcounter (TCNTS), timer cycle buffer register (TCBR), timer dead time data register (TDDR), timer cycle data register (TCDR), timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCOR), and timer A/D converter start request cycle set buffer registers (TADCOBR) are 16-bit registers. 16-bit read/writes is possible. 8-bit read/write is not possible. Always access in 16-bit units.

All registers other than the above registers are 8-bit registers. 8-bit read/writes is possible. 16-bit read/writes is not possible. Always access in 8-bit units.

10.4 Operation

10.4.1 Basic Functions

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, cycle counting, and external event counting.

Each TGR can be used as an input capture register or output compare register.

Always select functions for external pins of this module using the general I/O ports.

(1) Counter Operation

When one of bits CST0 to CST4 in TSTR is set to 1, the TCNT counter for the corresponding channel begins counting. TCNT can operate as a free-running counter, periodic counter, for example.

(a) Example of Count Operation Setting Procedure

Figure 10.4 shows an example of the count operation setting procedure.

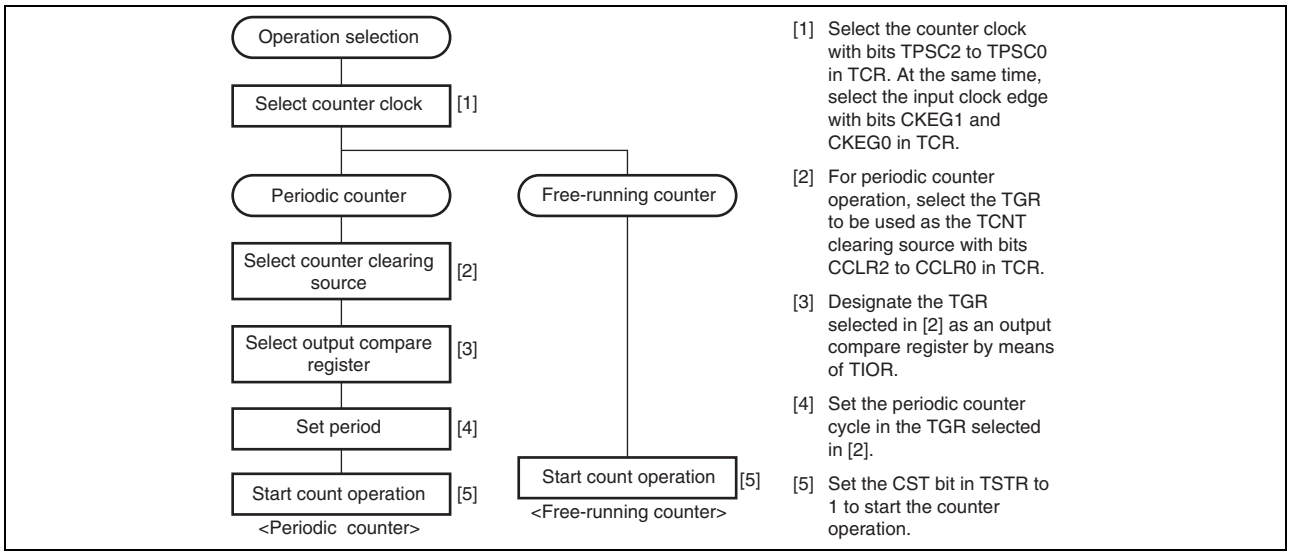

Figure 10.4 Example of Counter Operation Setting Procedure

(b) Free-Running Count Operation and Periodic Count Operation:

Immediately after a reset, the TCNT counters of this module are all designated as free-running counters. When the relevant bit in TSTR is set to 1 the corresponding TCNT counter starts up-count operation as a free-running counter. When TCNT overflows (from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. If the value of the corresponding TCIEV bit in TIER is 1 at this point, this module requests an interrupt. After overflow, TCNT starts counting up again from H'0000.

Figure 10.5 illustrates free-running counter operation.

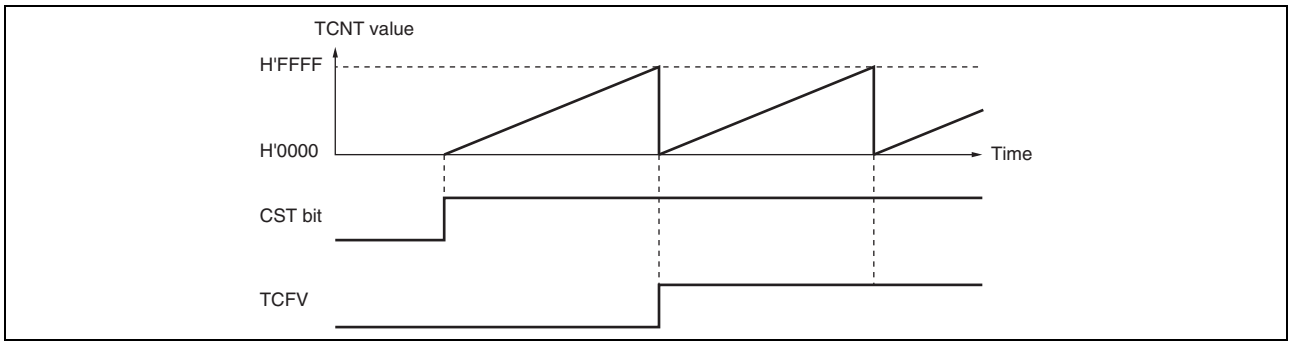

Figure 10.5 Free-Running Counter Operation

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR0 to CCLR2 in TCR. After the settings have been made, TCNT starts up-count operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding TGIE bit in TIER is 1 at this point, this module requests an interrupt. After a compare match, TCNT starts counting up again from H'0000.

Figure 10.6 illustrates periodic counter operation.

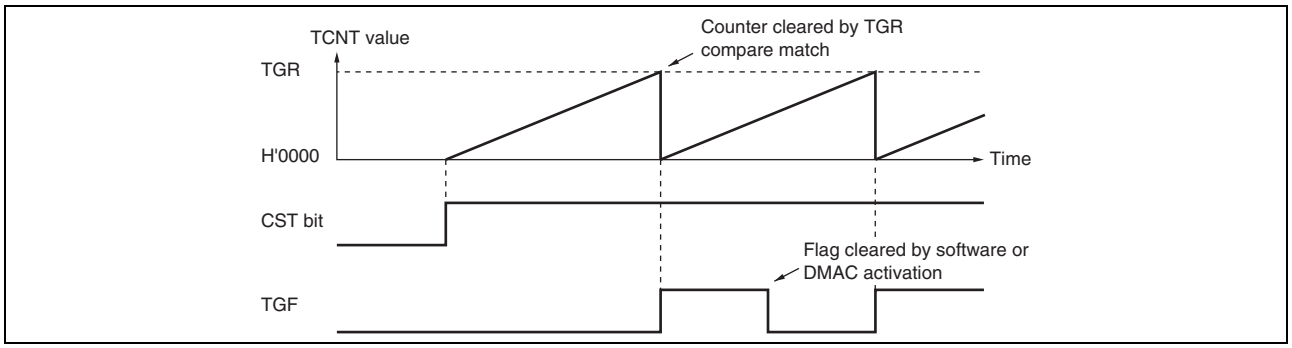

Figure 10.6 Periodic Counter Operation

(2) Waveform Output by Compare Match

This module can perform 0, 1, or toggle output from the corresponding output pin using compare match.

(a) Example of Setting Procedure for Waveform Output by Compare Match

Figure 10.7 shows an example of the setting procedure for waveform output by compare match.

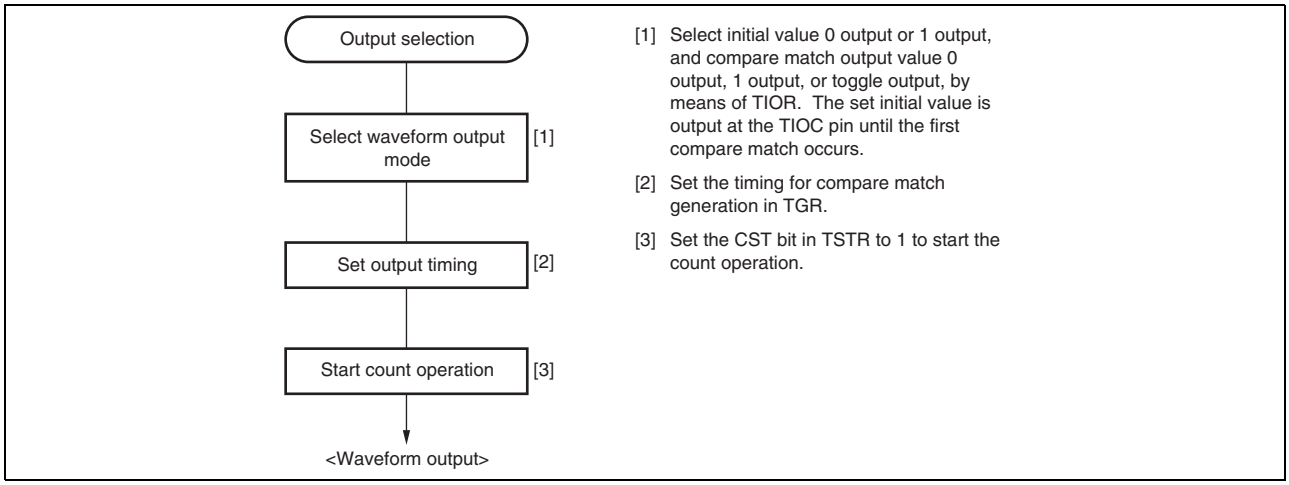

Figure 10.7 Example of Setting Procedure for Waveform Output by Compare Match

(b) Examples of Waveform Output Operation:

Figure 10.8 shows an example of 0 output/1 output.

In this example TCNT has been designated as a free-running counter, and settings have been made such that 1 is output by compare match A, and 0 is output by compare match B. When the set level and the pin level coincide, the pin level does not change.

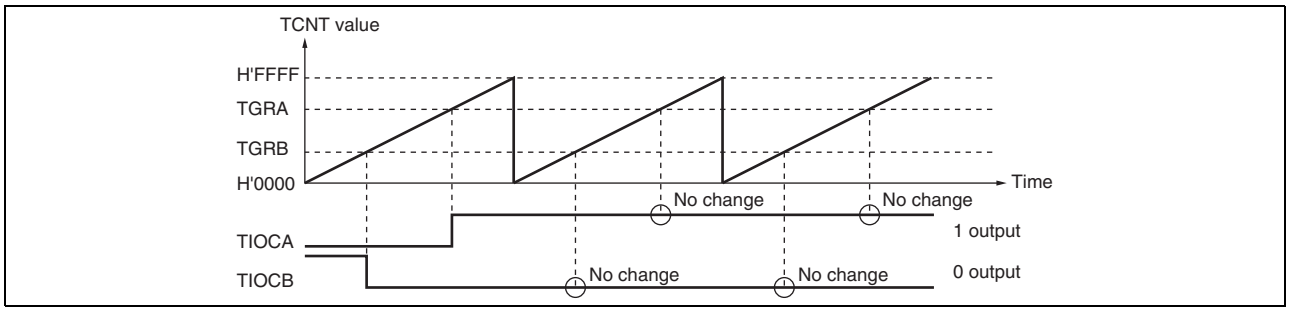

Figure 10.8 Example of 0 Output/1 Output Operation

Figure 10.9 shows an example of toggle output.

In this example, TCNT has been designated as a periodic counter (with counter clearing on compare match B), and settings have been made such that the output is toggled by both compare match A and compare match B.

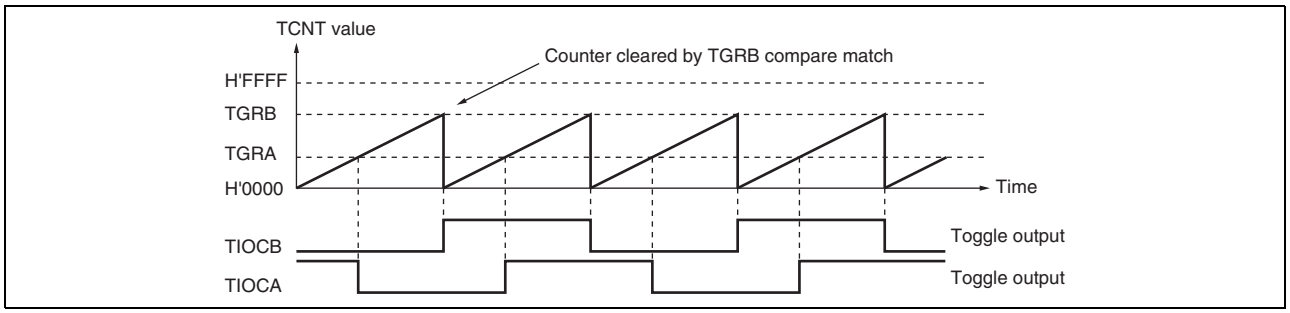

Figure 10.9 Example of Toggle Output Operation

(3) Input Capture Function

The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the detected edge. For channels 0 and 1, it is also possible to specify another channel's counter input clock or compare match signal as the input capture source.

Note: When another channel's counter input clock is used as the input capture input for channels 0 and 1, P0ϕ/1 should not be selected as the counter input clock used for input capture input. Input capture will not be generated if P0ϕ/1 is selected.

(a) Example of Input Capture Operation Setting Procedure

Figure 10.10 shows an example of the input capture operation setting procedure.

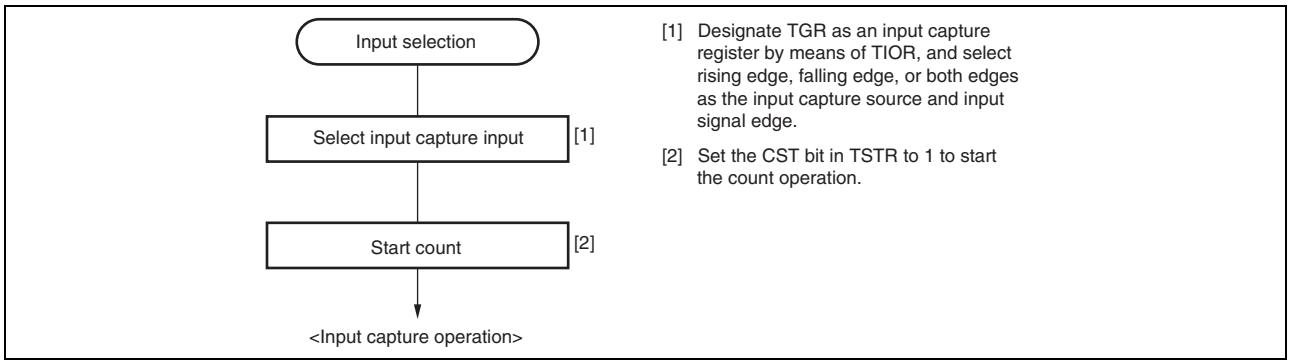

Figure 10.10 Example of Input Capture Operation Setting Procedure

(b) Example of Input Capture Operation

Figure 10.11 shows an example of input capture operation.

In this example both rising and falling edges have been selected as the TIOCA pin input capture input edge, the falling edge has been selected as the TIOCB pin input capture input edge, and counter clearing by TGRB input capture has been designated for TCNT.

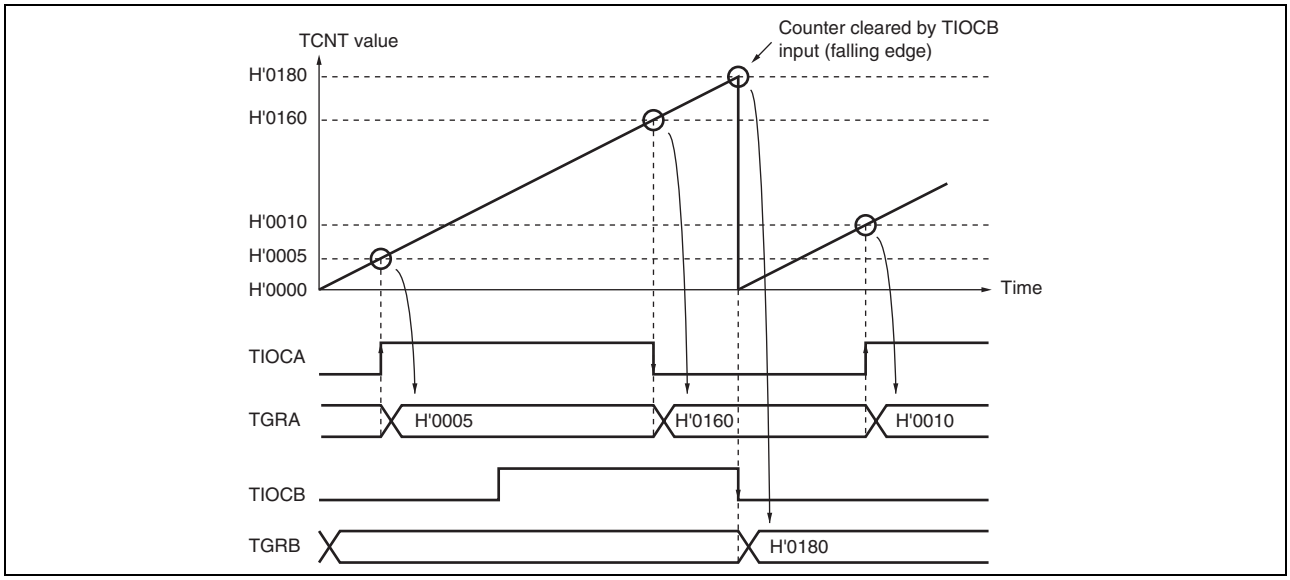

Figure 10.11 Example of Input Capture Operation

10.4.2 Synchronous Operation

In synchronous operation, the values in a number of TCNT counters can be rewritten simultaneously (synchronous presetting). Also, a number of TCNT counters can be cleared simultaneously by making the appropriate setting in TCR (synchronous clearing).

Synchronous operation enables TGR to be incremented with respect to a single time base.

Channels 0 to 4 can all be designated for synchronous operation.

(1) Example of Synchronous Operation Setting Procedure

Figure 10.12 shows an example of the synchronous operation setting procedure.

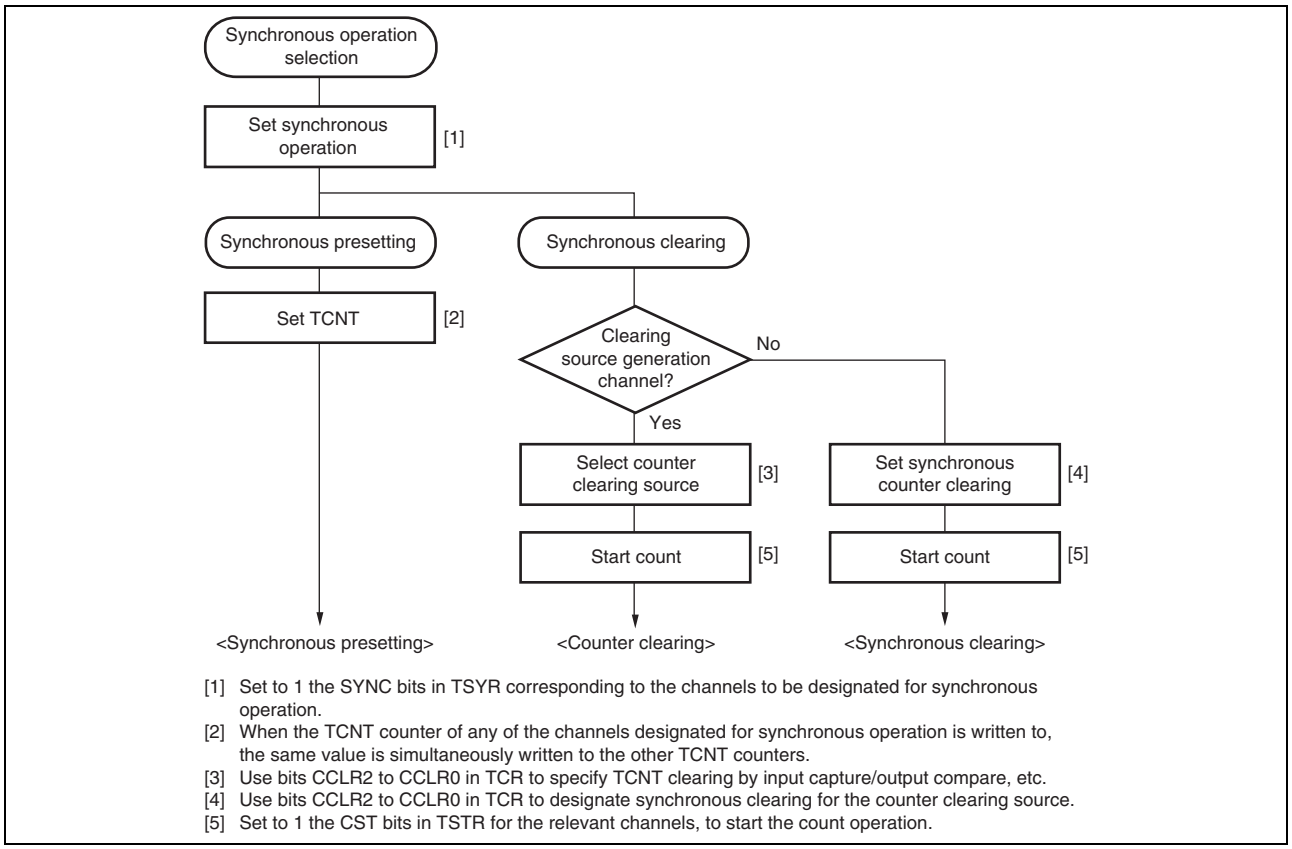

Figure 10.12 Example of Synchronous Operation Setting Procedure

(2) Example of Synchronous Operation

Figure 10.13 shows an example of synchronous operation.

In this example, synchronous operation and PWM mode 1 have been designated for channels 0 to 2, TGRB_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 and 2 counter clearing source.

Three-phase PWM waveforms are output from pins TIOC0A, TIOC1A, and TIOC2A. At this time, synchronous presetting, and synchronous clearing by TGRB_0 compare match, are performed for channel 0 to 2 TCNT counters, and the data set in TGRB_0 is used as the PWM cycle.

For details of PWM modes, see section 10.4.5, PWM Modes.

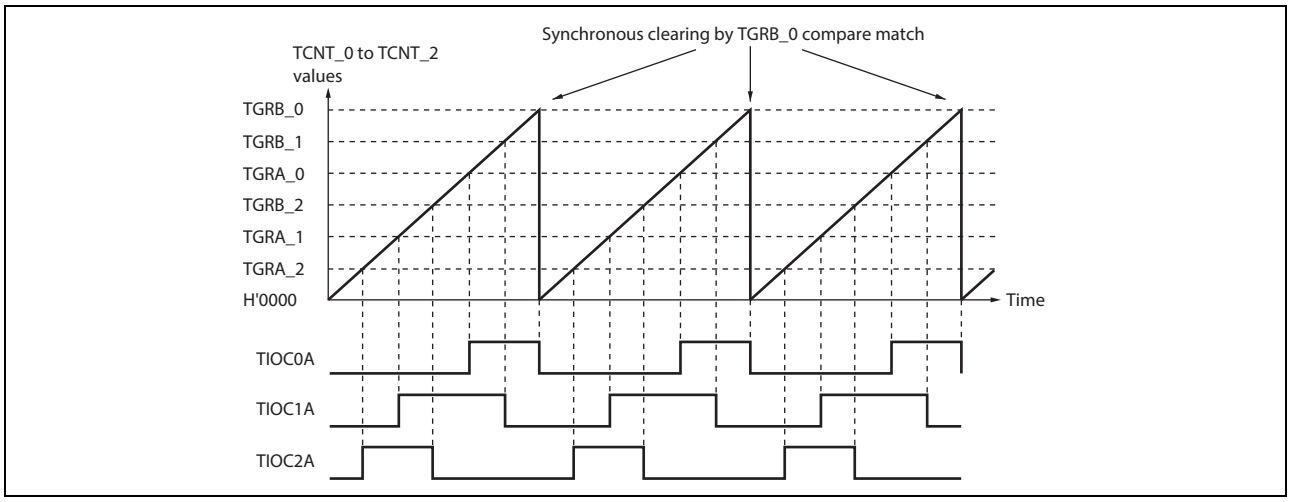

Figure 10.13 Example of Synchronous Operation

10.4.3 Buffer Operation

Buffer operation, provided for channels 0, 3, and 4, enables TGRC and TGRD to be used as buffer registers. In channel 0, TGRF can also be used as a buffer register.

Buffer operation differs depending on whether TGR has been designated as an input capture register or as a compare match register.

Note: TGRE_0 cannot be designated as an input capture register and can only operate as a compare match register.

Table 10.41 shows the register combinations used in buffer operation.

Table 10.41 Register Combinations in Buffer Operation

Channel	Timer General Register	Buffer Register
0	TGRA_0	TGRC_0
	TGRB_0	TGRD_0
	TGRE_0	TGRF_0
3	TGRA_3	TGRC_3
	TGRB_3	TGRD_3
4	TGRA_4	TGRC_4
	TGRB_4	TGRD_4

- When TGR is an output compare register
  When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.
  This operation is illustrated in Figure 10.14.

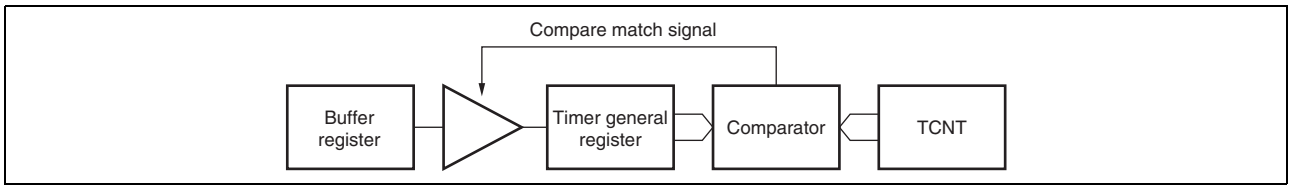

Figure 10.14 Compare Match Buffer Operation

- When TGR is an input capture register
  When input capture occurs, the value in TCNT is transferred to TGR and the value previously held in the timer general register is transferred to the buffer register.
  This operation is illustrated in Figure 10.15.

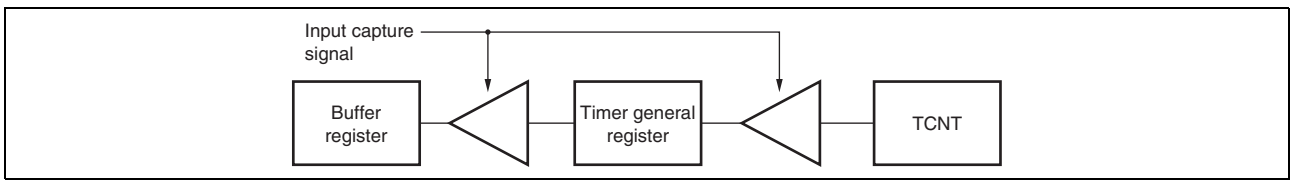

Figure 10.15 Input Capture Buffer Operation

(1) Example of Buffer Operation Setting Procedure

Figure 10.16 shows an example of the buffer operation setting procedure.

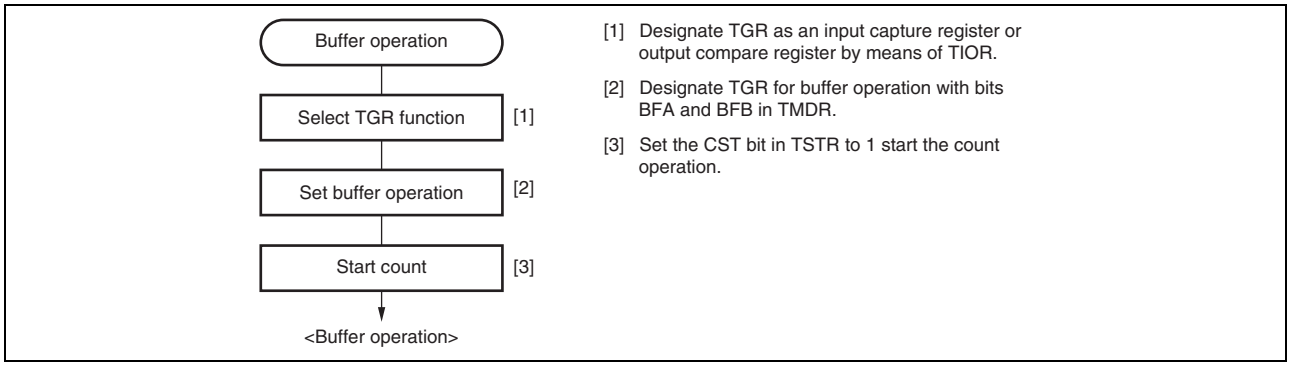

Figure 10.16 Example of Buffer Operation Setting Procedure

(2) Examples of Buffer Operation

(a) When TGR is an output compare register

Figure 10.17 shows an operation example in which PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used in this example are TCNT clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. In this example, the TTSA bit in TBTM is cleared to 0.

As buffer operation has been set, when compare match A occurs the output changes and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA. This operation is repeated each time that compare match A occurs.

For details of PWM modes, see section 10.4.5, PWM Modes.

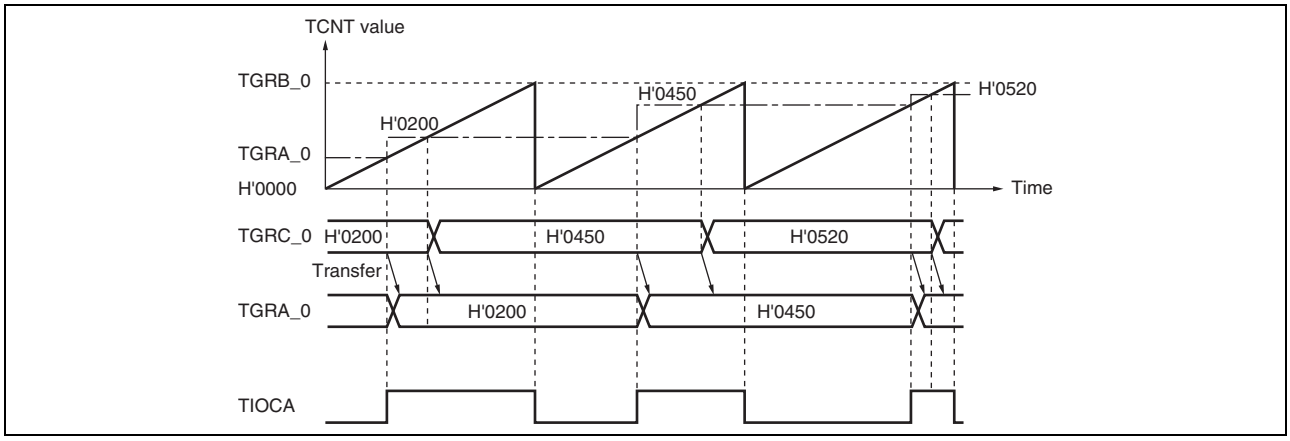

Figure 10.17 Example of Buffer Operation (1)

(b) When TGR is an input capture register

Figure 10.18 shows an operation example in which TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC.

Counter clearing by TGRA input capture has been set for TCNT, and both rising and falling edges have been selected as the TIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in TGRA upon the occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

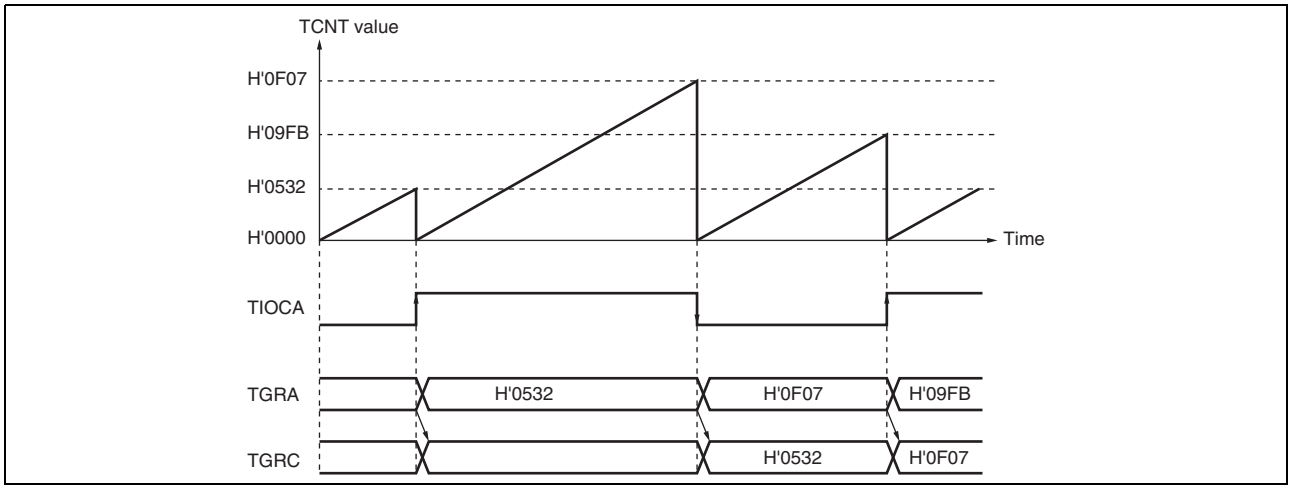

Figure 10.18 Example of Buffer Operation (2)

(3) Selecting Timing for Transfer from Buffer Registers to Timer General Registers in Buffer Operation

The timing for transfer from buffer registers to timer general registers can be selected in PWM mode 1 or 2 for channel 0 or in PWM mode 1 for channels 3 and 4 by setting the buffer operation transfer mode registers (TBTM_0, TBTM_3, and TBTM_4). Either compare match (initial setting) or TCNT clearing can be selected for the transfer timing. TCNT clearing as transfer timing is one of the following cases.

- When TCNT overflows (H'FFFF to H'0000)
- When H'0000 is written to TCNT during counting
- When TCNT is cleared to H'0000 under the condition specified in the CCLR2 to CCLR0 bits in TCR

Note: TBTM must be modified only while TCNT stops.

Figure 10.19 shows an operation example in which PWM mode 1 is designated for channel 0 and buffer operation is designated for TGRA_0 and TGRC_0. The settings used in this example are TCNT_0 clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. The TTSA bit in TBTM_0 is set to 1.

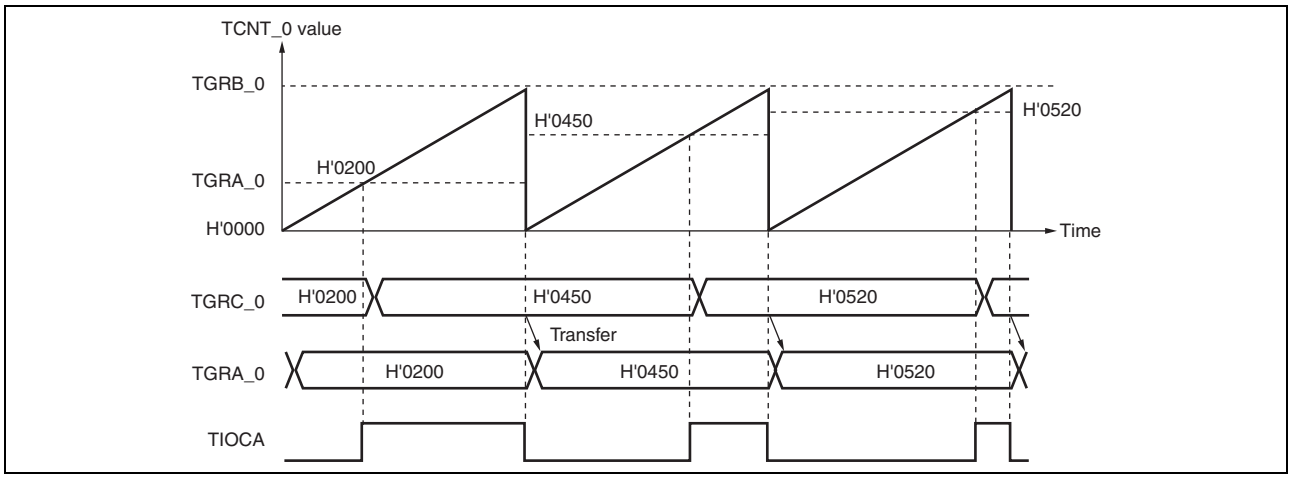

Figure 10.19 Example of Buffer Operation When TCNT_0 Clearing is Selected for TGRC_0 to TGRA_0 Transfer Timing

10.4.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.

This function works by counting the channel 1 counter clock upon overflow/underflow of TCNT_2 as set in bits TPSC0 to TPSC2 in TCR.

Underflow occurs only when the lower 16-bit TCNT is in phase-counting mode.

Table 10.42 shows the register combinations used in cascaded operation.

Note: When phase counting mode is set for channel 1, the counter clock setting is invalid and the counters operates independently in phase counting mode.

Table 10.42 Cascaded Combinations

Combination	Upper 16 Bits	Lower 16 Bits
Channels 1 and 2	TCNT_1	TCNT_2

For simultaneous input capture of TCNT_1 and TCNT_2 during cascaded operation, additional input capture input pins can be specified by the input capture control register (TICCR). The condition for input capture is the detection of an edge in the signal obtained from the logical OR of the signal on the main input pin and the signal on the additional input pin. For details, see (4), Cascaded Operation Example (c). For input capture in cascade connection, refer to section 10.7.22, Simultaneous Capture of TCNT_1 and TCNT_2 in Cascade Connection.

Table 10.43 show the TICCR setting and input capture input pins.

Table 10.43 TICCR Setting and Input Capture Input Pins

Target Input Capture	TICCR Setting	Input Capture Input Pins
Input capture from TCNT_1 to TGRA_1	I2AE bit = 0 (initial value)	TIOC1A
	I2AE bit = 1	TIOC1A, TIOC2A
Input capture from TCNT_1 to TGRB_1	I2BE bit = 0 (initial value)	TIOC1B
	I2BE bit = 1	TIOC1B, TIOC2B
Input capture from TCNT_2 to TGRA_2	I1AE bit = 0 (initial value)	TIOC2A
	I1AE bit = 1	TIOC2A, TIOC1A
Input capture from TCNT_2 to TGRB_2	I1BE bit = 0 (initial value)	TIOC2B
	I1BE bit = 1	TIOC2B, TIOC1B

(1) Example of Cascaded Operation Setting Procedure

Figure 10.20 shows an example of the setting procedure for cascaded operation.

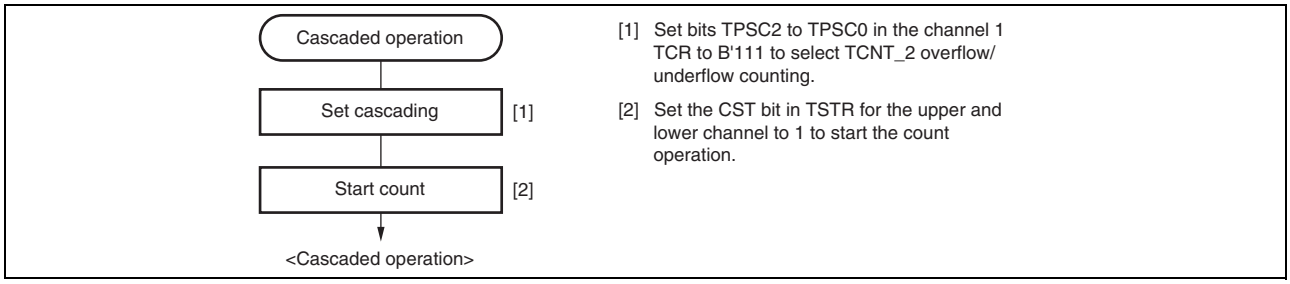

Figure 10.20 Cascaded Operation Setting Procedure

(2) Cascaded Operation Example (a)

Figure 10.21 illustrates the operation when TCNT_2 overflow/underflow counting has been set for TCNT_1 and phase counting mode has been designated for channel 2.

TCNT_1 is incremented by TCNT_2 overflow and decremented by TCNT_2 underflow.

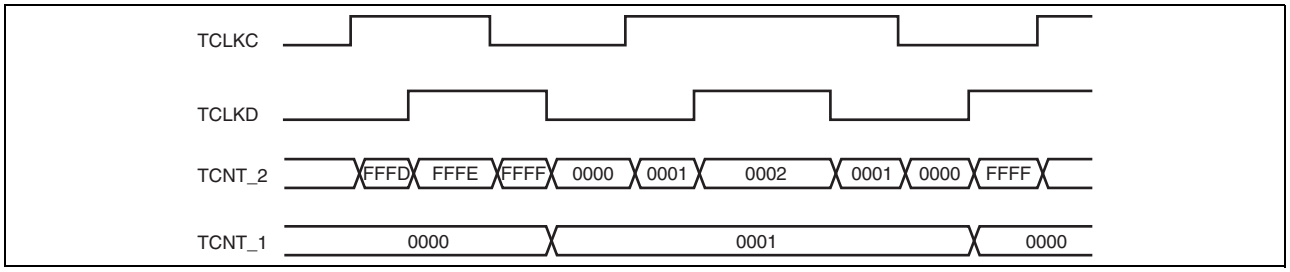

Figure 10.21 Cascaded Operation Example (a)

(3) Cascaded Operation Example (b)

Figure 10.22 illustrates the operation when TCNT_1 and TCNT_2 have been cascaded and the I2AE bit in TICCR has been set to 1 to include the TIOC2A pin in the TGRA_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR_1 have selected the TIOC1A rising edge for the input capture timing while the IOA0 to IOA3 bits in TIOR_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, the rising edge of both TIOC1A and TIOC2A is used for the TGRA_1 input capture condition. For the TGRA_2 input capture condition, the TIOC2A rising edge is used.

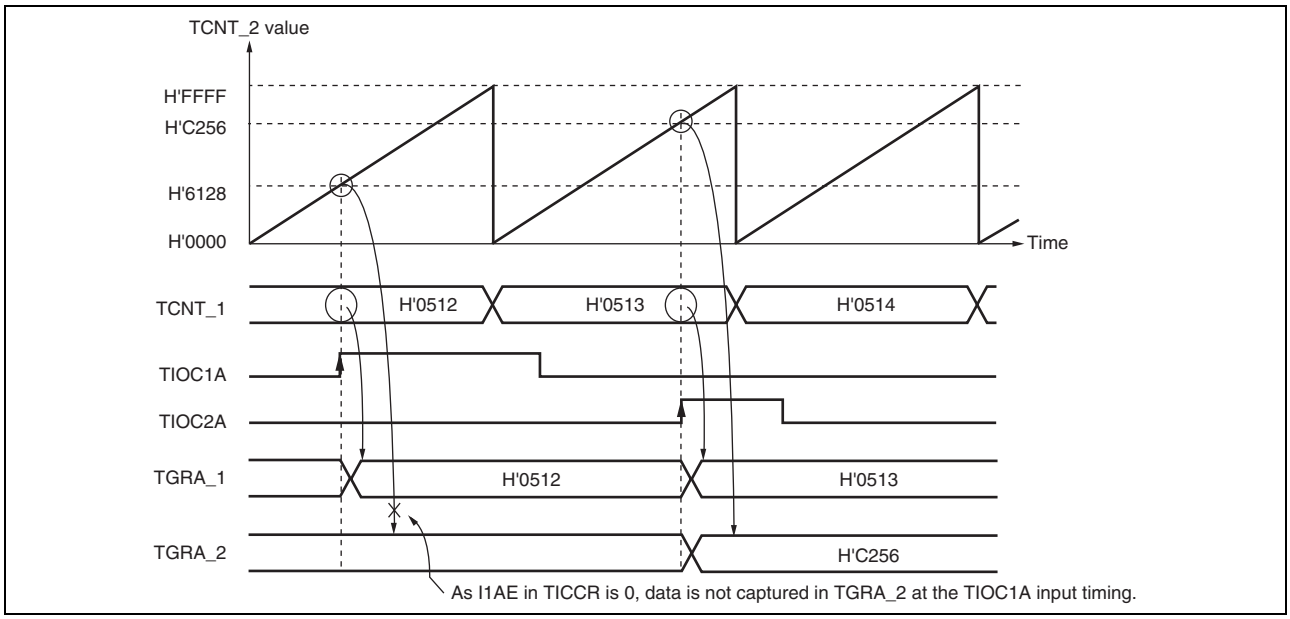

Figure 10.22 Cascaded Operation Example (b)

(4) Cascaded Operation Example (c)

Figure 10.23 illustrates the operation when TCNT_1 and TCNT_2 have been cascaded and the I2AE and I1AE bits in TICCR have been set to 1 to include the TIOC2A and TIOC1A pins in the TGRA_1 and TGRA_2 input capture conditions, respectively. In this example, the IOA0 to IOA3 bits in both TIOR_1 and TIOR_2 have selected both the rising and falling edges for the input capture timing. Under these conditions, the ORed result of TIOC1A and TIOC2A input is used for the TGRA_1 and TGRA_2 input capture conditions.

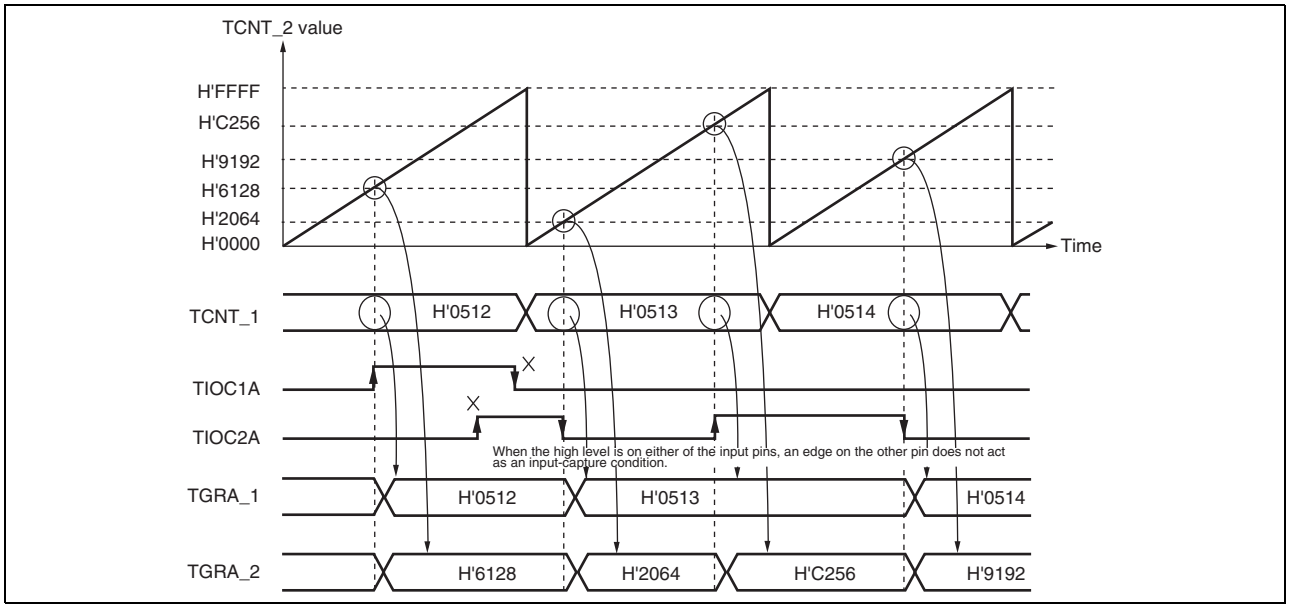

Figure 10.23 Cascaded Operation Example (c)

(5) Cascaded Operation Example (d)

Figure 10.24 illustrates the operation when TCNT_1 and TCNT_2 have been cascaded and the I2AE bit in TICCR has been set to 1 to include the TIOC2A pin in the TGRA_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR_1 have selected TGRA_0 compare match or input capture occurrence for the input capture timing while the IOA0 to IOA3 bits in TIOR_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, as TIOR_1 has selected TGRA_0 compare match or input capture occurrence for the input capture timing, the TIOC2A edge is not used for TGRA_1 input capture condition although the I2AE bit in TICCR has been set to 1.

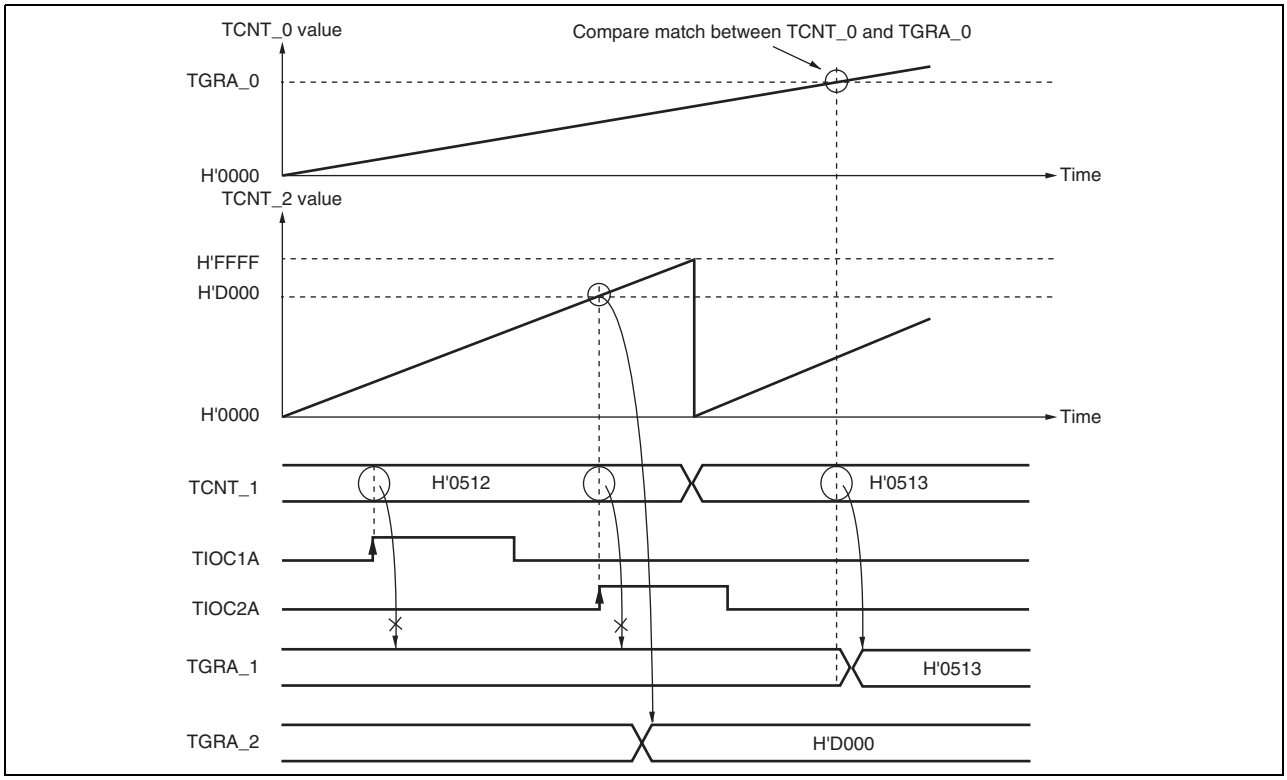

Figure 10.24 Cascaded Operation Example (d)

10.4.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. The output level can be selected as 0, 1, or toggle output in response to a compare match of each TGR.

TGR registers settings can be used to output a PWM waveform in the range of 0% to 100% duty.

Designating TGR compare match as the counter clearing source enables the period to be set in that register. All channels can be designated for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

- PWM mode 1
  PWM output is generated from the TIOCA and TIOCC pins by pairing TGRA with TGRB and TGRC with TGRD. The output specified by bits IOA0 to IOA3 and IOC0 to IOC3 in TIOR is output from the TIOCA and TIOCC pins at compare matches A and C, and the output specified by bits IOB0 to IOB3 and IOD0 to IOD3 in TIOR is output at compare matches B and D. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRs are identical, the output value does not change when a compare match occurs.
  In PWM mode 1, a maximum 8-phase PWM output is possible.
- PWM mode 2
  PWM output is generated using one TGR as the cycle register and the others as duty registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by a cycle register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty registers are identical, the output value does not change when a compare match occurs.
  In PWM mode 2, a maximum 8-phase PWM output is possible in combination use with synchronous operation.

The correspondence between PWM output pins and registers is shown in Table 10.44.

Table 10.44 PWM Output Registers and Output Pins

		Output Pins	
Channel	**Registers**	**PWM Mode 1**	**PWM Mode 2**
0	TGRA_0	TIOC0A	TIOC0A
	TGRB_0		TIOC0B
	TGRC_0	TIOC0C	TIOC0C
	TGRD_0		TIOC0D
1	TGRA_1	TIOC1A	TIOC1A
	TGRB_1		TIOC1B
2	TGRA_2	TIOC2A	TIOC2A
	TGRB_2		TIOC2B
3	TGRA_3	TIOC3A	Cannot be set
	TGRB_3		Cannot be set
	TGRC_3	TIOC3C	Cannot be set
	TGRD_3		Cannot be set
4	TGRA_4	TIOC4A	Cannot be set
	TGRB_4		Cannot be set
	TGRC_4	TIOC4C	Cannot be set
	TGRD_4		Cannot be set

Note: In PWM mode 2, PWM output is not possible for the TGR register in which the period is set.

(1) Example of PWM Mode Setting Procedure

Figure 10.25 shows an example of the PWM mode setting procedure.

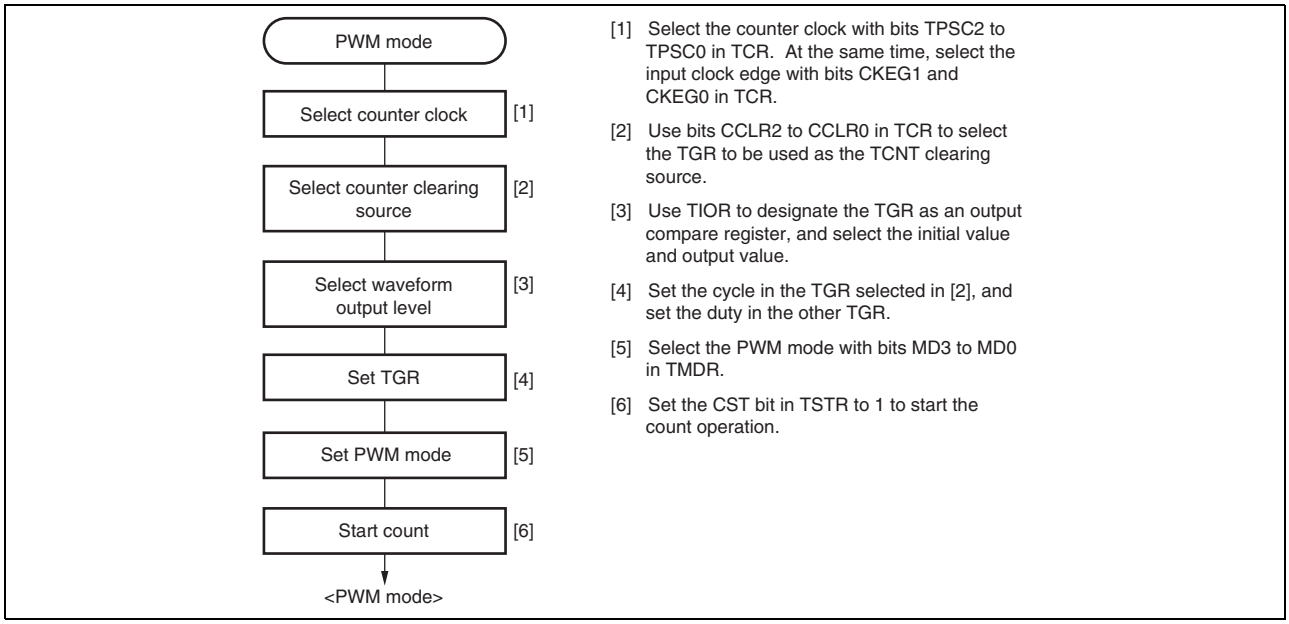

Figure 10.25 Example of PWM Mode Setting Procedure

(2) Examples of PWM Mode Operation

Figure 10.26 shows an example of PWM mode 1 operation.

In this example, TGRA compare match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value.

In this case, the value set in TGRA is used as the period, and the values set in the TGRB registers are used as the duty levels.

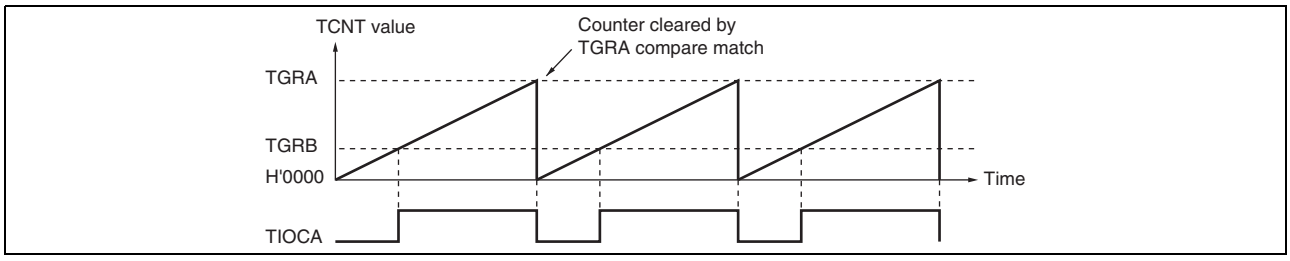

Figure 10.26 Example of PWM Mode Operation (1)

Figure 10.27 shows an example of PWM mode 2 operation.

In this example, synchronous operation is designated for channels 0 and 1, TGRB_1 compare match is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers (TGRA_0 to TGRD_0, TGRA_1), outputting a 5-phase PWM waveform.

In this case, the value set in TGRB_1 is used as the cycle, and the values set in the other TGRs are used as the duty levels.

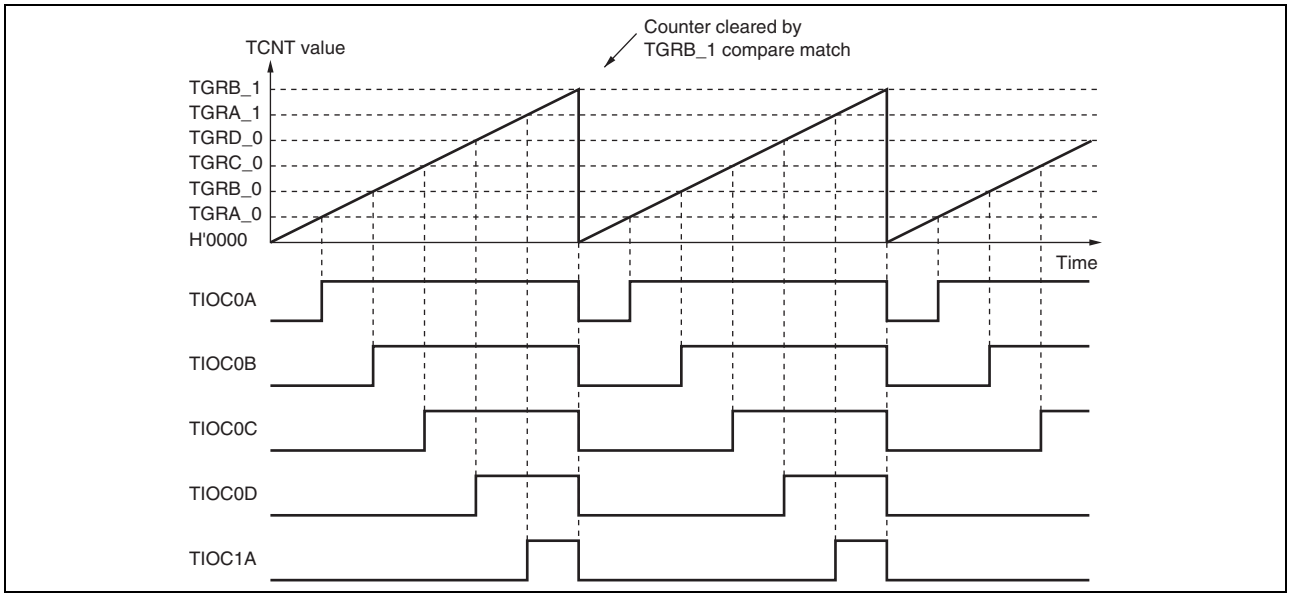

Figure 10.27 Example of PWM Mode Operation (2)

Figure 10.28 shows examples of PWM waveform output with 0% duty and 100% duty in PWM mode.

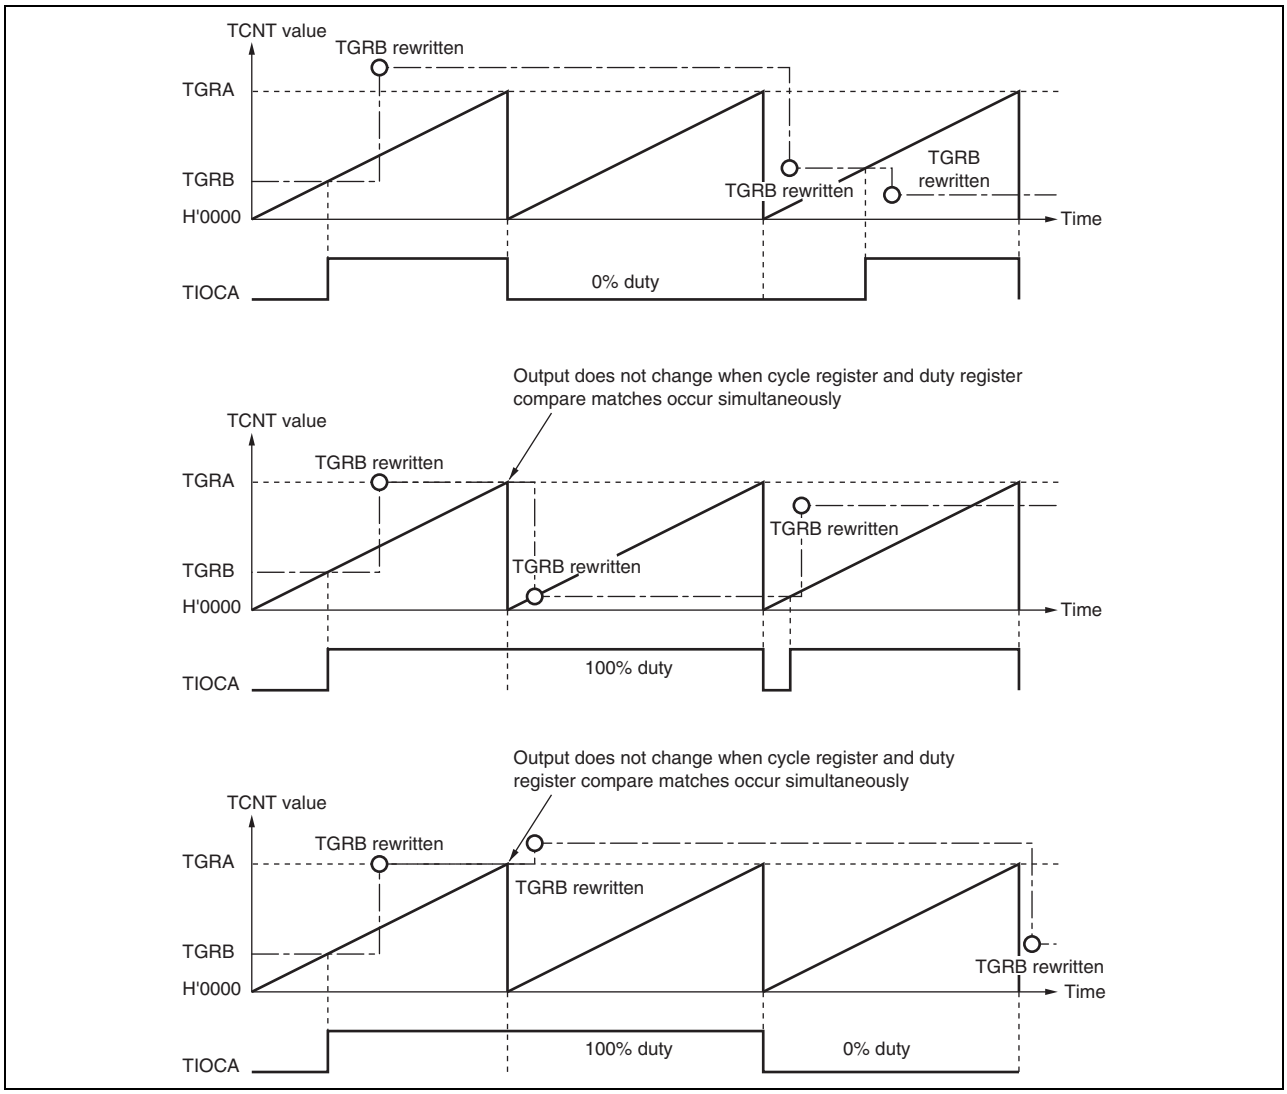

Figure 10.28 Example of PWM Mode Operation (3)

10.4.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT is incremented/decremented accordingly. This mode can be set for channels 1 and 2.

When phase counting mode is set, an external clock is selected as the counter input clock and TCNT operates as an up/down-counter regardless of the setting of bits TPSC0 to TPSC2 and bits CKEG0 and CKEG1 in TCR. However, the functions of bits CCLR0 and CCLR1 in TCR, and of TIOR, TIER, and TGR, are valid, and input capture/compare match and interrupt functions can be used.

This can be used for two-phase encoder pulse input.

If overflow occurs when TCNT is counting up, the TCFV flag in TSR is set; if underflow occurs when TCNT is counting down, the TCFU flag is set.

The TCFD bit in TSR is the count direction flag. Reading the TCFD flag reveals whether TCNT is counting up or down.

Table 10.45 shows the correspondence between external clock pins and channels.

Table 10.45 Phase Counting Mode Clock Input Pins

	External Clock Pins	
Channels	**A-Phase**	**B-Phase**
When channel 1 is set to phase counting mode	TCLKA	TCLKB
When channel 2 is set to phase counting mode	TCLKC	TCLKD

(1) Example of Phase Counting Mode Setting Procedure

Figure 10.29 shows an example of the phase counting mode setting procedure.

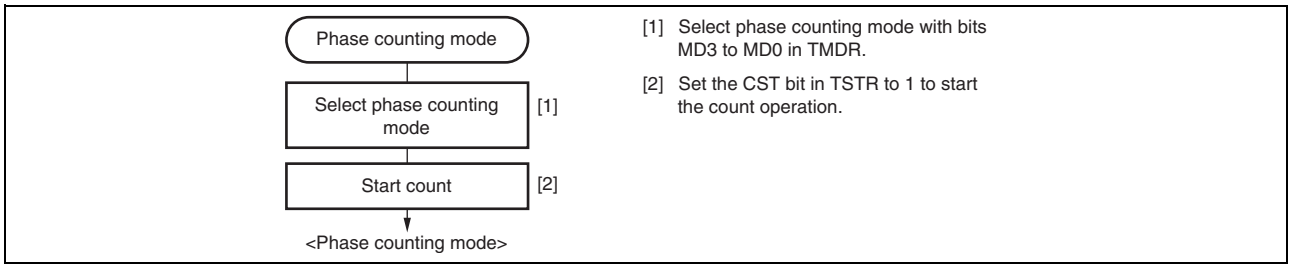

Figure 10.29 Example of Phase Counting Mode Setting Procedure

(2) Examples of Phase Counting Mode Operation

In phase counting mode, TCNT counts up or down according to the phase difference between two external clocks. There are four modes, according to the count conditions.

(a) Phase counting mode 1

Figure 10.30 shows an example of phase counting mode 1 operation, and Table 10.46 summarizes the TCNT up/down-count conditions.

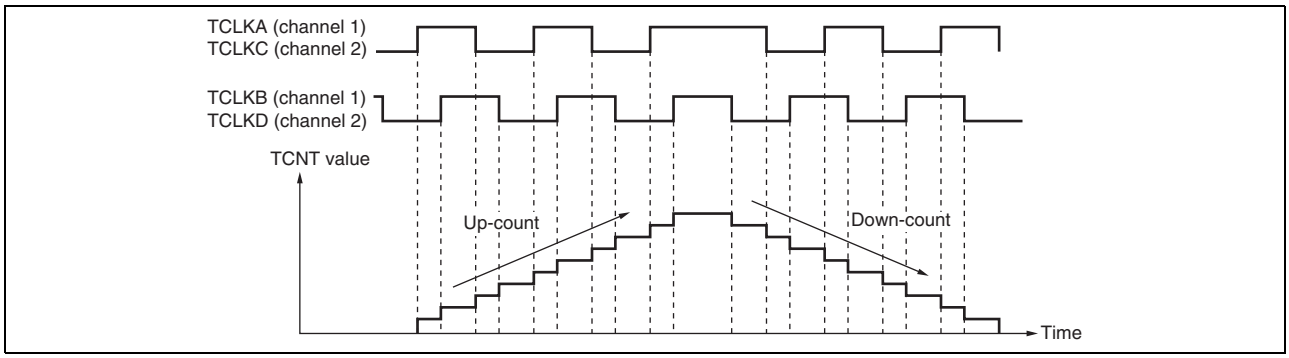

Figure 10.30 Example of Phase Counting Mode 1 Operation

(3) Phase Counting Mode Application Example

Figure 10.34 shows an example in which channel 1 is in phase counting mode, and channel 1 is coupled with channel 0 to input servo motor 2-phase encoder pulses in order to detect position or speed.

Channel 1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to TCLKA and TCLKB.

Channel 0 operates with TCNT counter clearing by TGRC_0 compare match; TGRA_0 and TGRC_0 are used for the compare match function and are set with the speed control period and position control period. TGRB_0 is used for input capture, with TGRB_0 and TGRD_0 operating in buffer mode. The channel 1 counter input clock is designated as the TGRB_0 input capture source, and the pulse widths of 2-phase encoder 4-multiplication pulses are detected.

TGRA_1 and TGRB_1 for channel 1 are designated for input capture, and channel 0 TGRA_0 and TGRC_0 compare matches are selected as the input capture source and store the up/down-counter values for the control periods.

This procedure enables the accurate detection of position and speed.

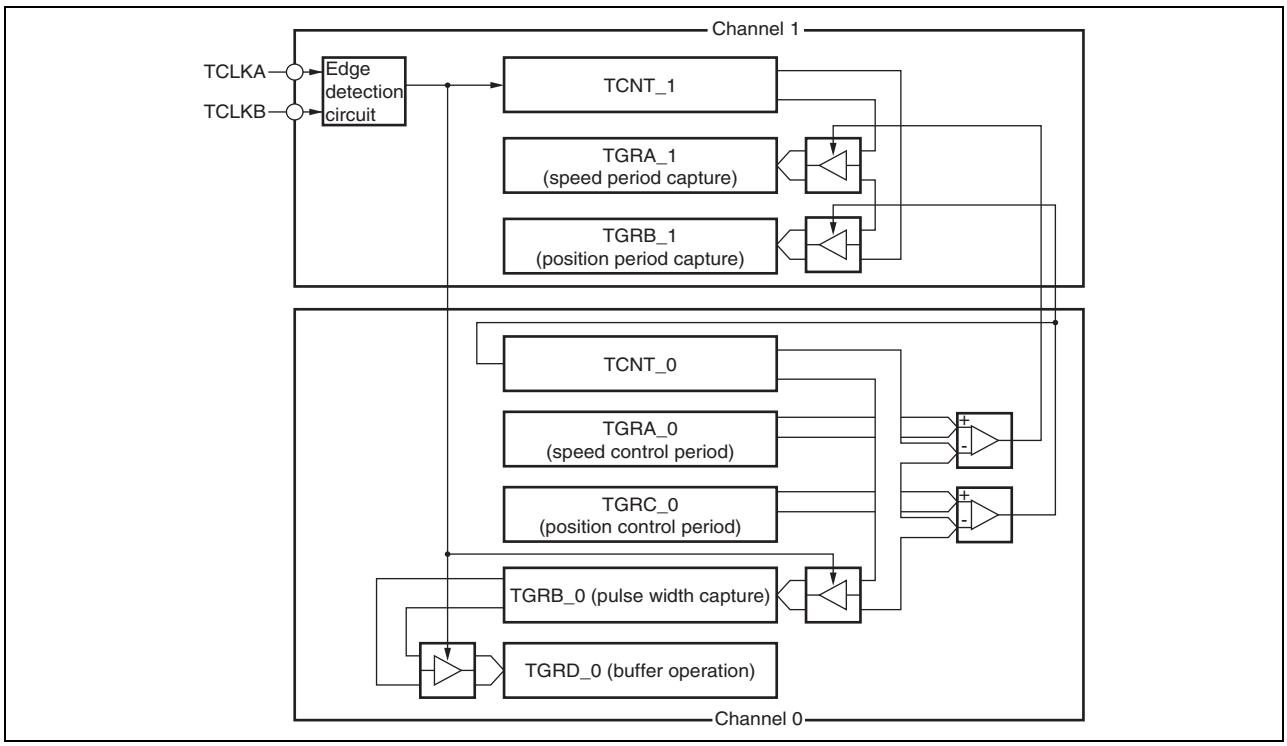

Figure 10.34 Phase Counting Mode Application Example

10.4.7 Reset-Synchronized PWM Mode

In the reset-synchronized PWM mode, three-phase output of positive and negative PWM waveforms that share a common wave transition point can be obtained by combining channels 3 and 4.

When set for reset-synchronized PWM mode, the TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, and TIOC4D pins function as PWM output pins and TCNT_3 functions as an upcounter.

Table 10.50 shows the PWM output pins used. Table 10.51 shows the settings of the registers.

Table 10.50 Output Pins for Reset-Synchronized PWM Mode

Channel	Output Pin	Description
3	TIOC3B	PWM output pin 1
	TIOC3D	PWM output pin 1' (negative-phase waveform of PWM output 1)
4	TIOC4A	PWM output pin 2
	TIOC4C	PWM output pin 2' (negative-phase waveform of PWM output 2)
	TIOC4B	PWM output pin 3
	TIOC4D	PWM output pin 3' (negative-phase waveform of PWM output 3)

Table 10.51 Register Settings for Reset-Synchronized PWM Mode

Register	Description of Setting
TCNT_3	Initial setting of H'0000
TCNT_4	Initial setting of H'0000
TGRA_3	Set count cycle for TCNT_3
TGRB_3	Sets the turning point for PWM waveform output by the TIOC3B and TIOC3D pins
TGRA_4	Sets the turning point for PWM waveform output by the TIOC4A and TIOC4C pins
TGRB_4	Sets the turning point for PWM waveform output by the TIOC4B and TIOC4D pins

(1) Procedure for Selecting the Reset-Synchronized PWM Mode

Figure 10.35 shows an example of procedure for selecting the reset synchronized PWM mode.

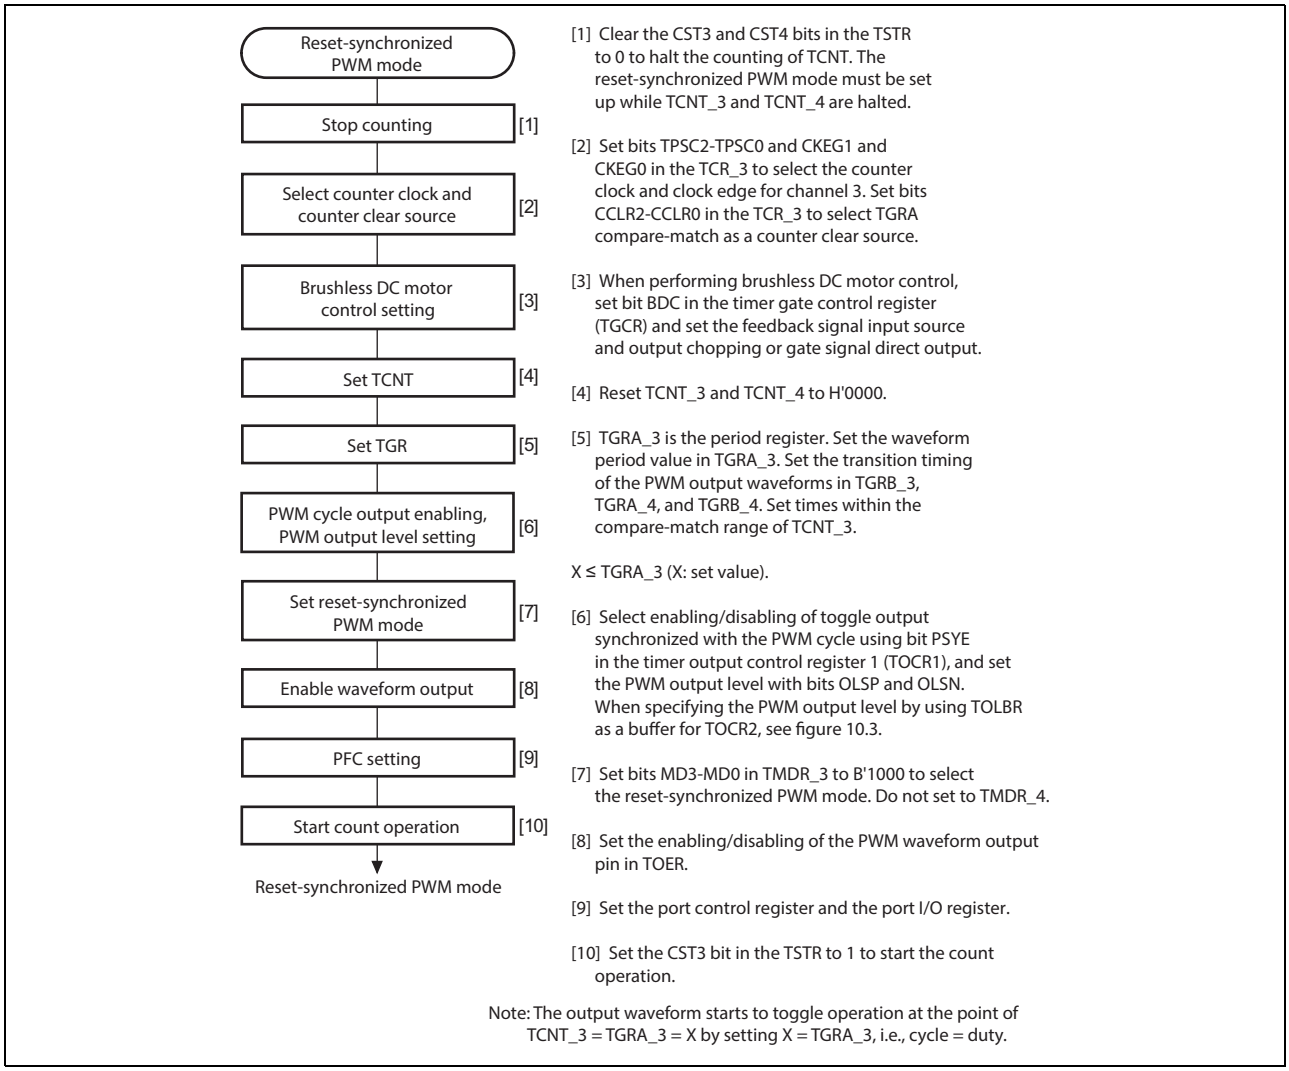

Figure 10.35 Procedure for Selecting Reset-Synchronized PWM Mode

(2) Reset-Synchronized PWM Mode Operation

Figure 10.36 shows an example of operation in the reset-synchronized PWM mode. TCNT_3 and TCNT_4 operate as upcounters. The counter is cleared when a TCNT_3 and TGRA_3 compare-match occurs, and then begins incrementing from H'0000. The PWM output pin output toggles with each occurrence of a TGRB_3, TGRA_4, TGRB_4 compare-match, and upon counter clears.

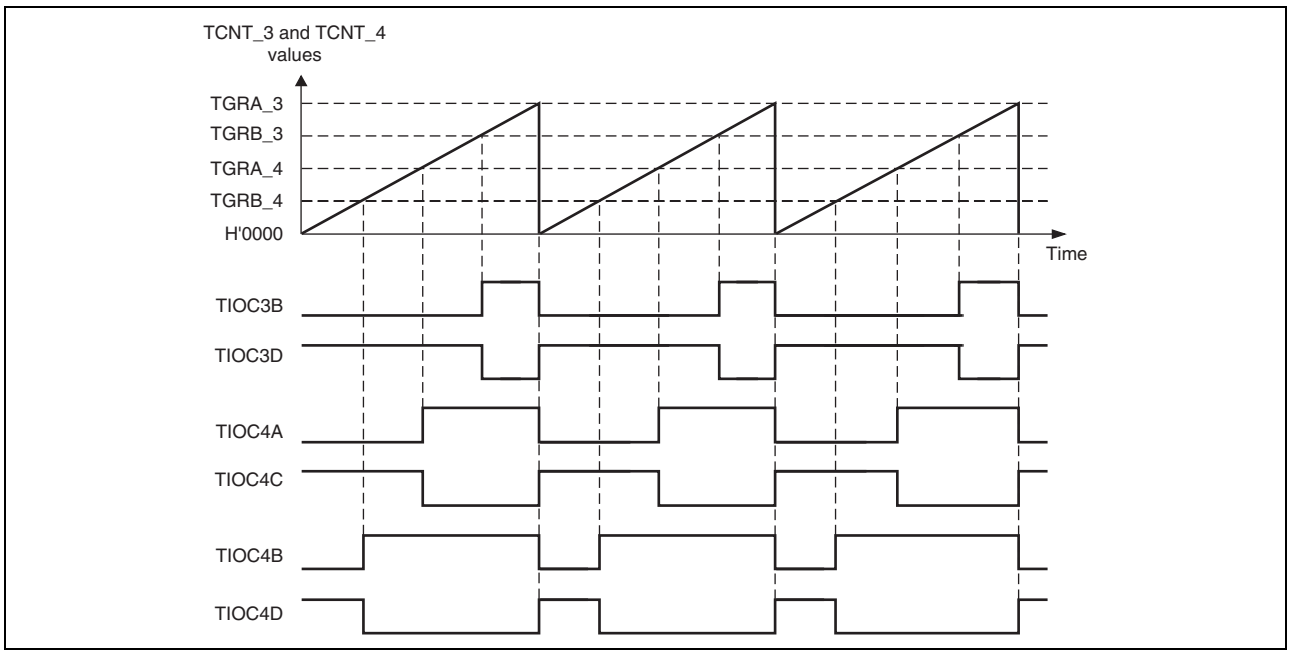

Figure 10.36 Reset-Synchronized PWM Mode Operation Example (When TOCR's OLSN = 1 and OLSP = 1)

10.4.8 Complementary PWM Mode

In the complementary PWM mode, three-phase output of non-overlapping positive and negative PWM waveforms can be obtained by combining channels 3 and 4. PWM waveforms without non-overlapping interval are also available.

In complementary PWM mode, TIOC3B, TIOC3D, TIOC4A, TIOC4B, TIOC4C, and TIOC4D pins function as PWM output pins, the TIOC3A pin can be set for toggle output synchronized with the PWM period. TCNT_3 and TCNT_4 function as up/down counters.

Table 10.52 shows the PWM output pins used. Table 10.53 shows the settings of the registers used.

Table 10.52 Output Pins for Complementary PWM Mode

Channel	Output Pin	Description
3	TIOC3A	Toggle output synchronized with PWM period (or I/O port)
	TIOC3B	PWM output pin 1
	TIOC3C	I/O port*
	TIOC3D	PWM output pin 1' (non-overlapping negative-phase waveform of PWM output 1; PWM output without non-overlapping interval is also available)
4	TIOC4A	PWM output pin 2
	TIOC4B	PWM output pin 3
	TIOC4C	PWM output pin 2' (non-overlapping negative-phase waveform of PWM output 2; PWM output without non-overlapping interval is also available)
	TIOC4D	PWM output pin 3' (non-overlapping negative-phase waveform of PWM output 3; PWM output without non-overlapping interval is also available)

Note: * Avoid setting the TIOC3C pin as a timer I/O pin in the complementary PWM mode.

Table 10.53 Register Settings for Complementary PWM Mode

Channel	Counter/Register	Description	Read/Write from CPU
3	TCNT_3	Start of up-count from value set in dead time register	Maskable by TRWER setting*
	TGRA_3	Set TCNT_3 upper limit value (1/2 carrier cycle + dead time)	Maskable by TRWER setting*
	TGRB_3	PWM output 1 compare register	Maskable by TRWER setting*
	TGRC_3	TGRA_3 buffer register	Always readable/writable
	TGRD_3	PWM output 1/TGRB_3 buffer register	Always readable/writable
4	TCNT_4	Up-count start, initialized to H'0000	Maskable by TRWER setting*
	TGRA_4	PWM output 2 compare register	Maskable by TRWER setting*
	TGRB_4	PWM output 3 compare register	Maskable by TRWER setting*
	TGRC_4	PWM output 2/TGRA_4 buffer register	Always readable/writable
	TGRD_4	PWM output 3/TGRB_4 buffer register	Always readable/writable
Timer dead time data register (TDDR)		Set TCNT_4 and TCNT_3 offset value (dead time value)	Maskable by TRWER setting*
Timer cycle data register (TCDR)		Set TCNT_4 upper limit value (1/2 carrier cycle)	Maskable by TRWER setting*
Timer cycle buffer register (TCBR)		TCDR buffer register	Always readable/writable
Subcounter (TCNTS)		Subcounter for dead time generation	Read-only
Temporary register 1 (TEMP1)		PWM output 1/TGRB_3 temporary register	Not readable/writable
Temporary register 2 (TEMP2)		PWM output 2/TGRA_4 temporary register	Not readable/writable
Temporary register 3 (TEMP3)		PWM output 3/TGRB_4 temporary register	Not readable/writable

Note: * Access can be enabled or disabled according to the setting of bit 0 (RWE) in TRWER (timer read/write enable register).

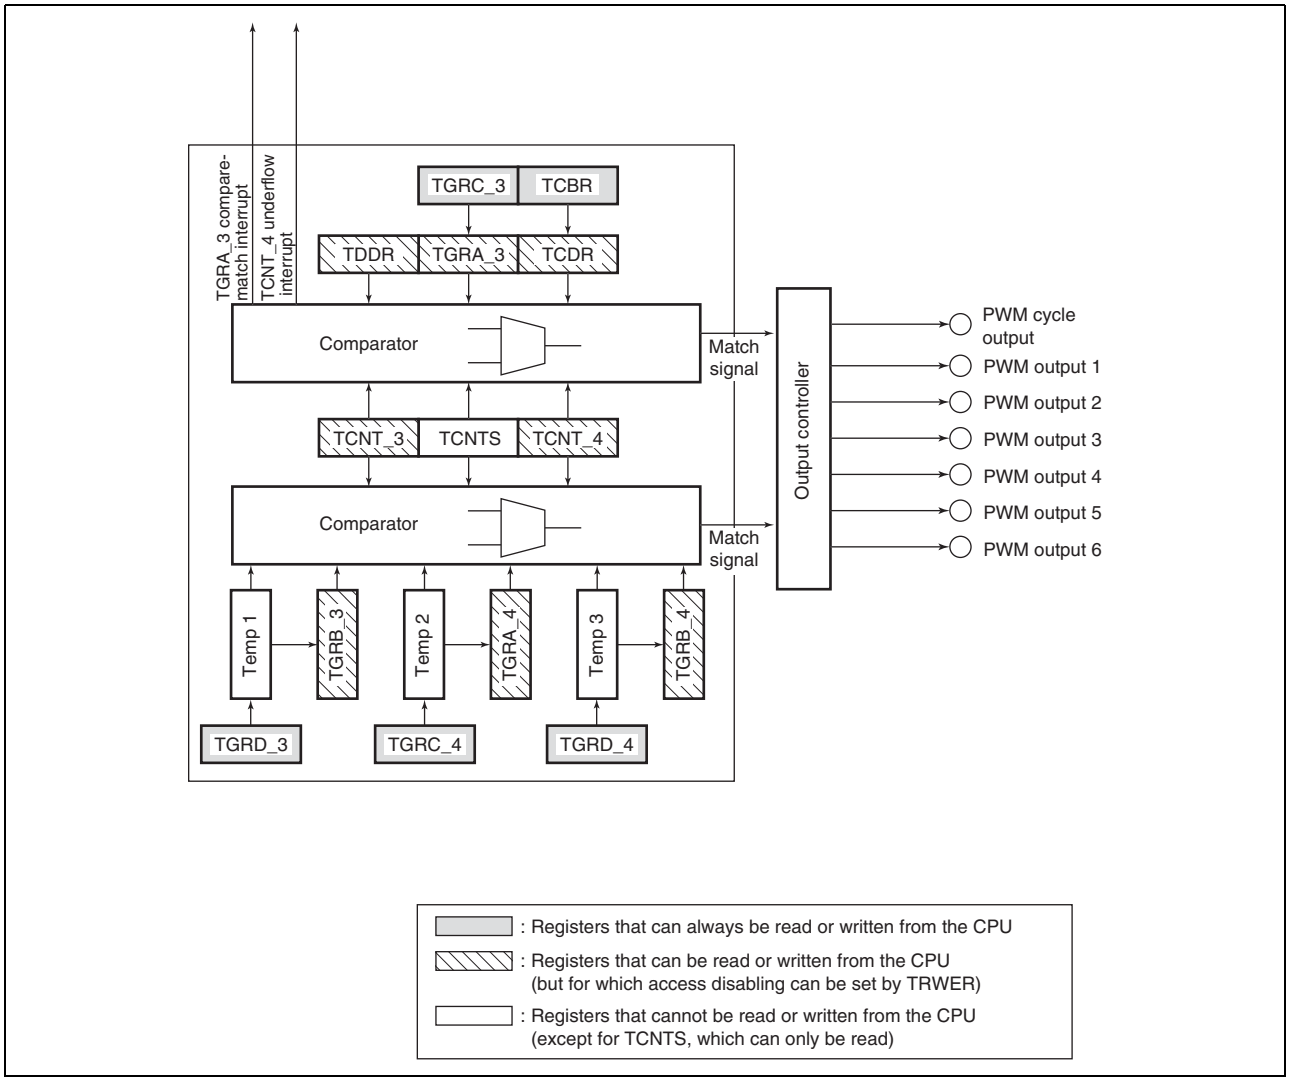

Figure 10.37 Block Diagram of Channels 3 and 4 in Complementary PWM Mode

(1) Example of Complementary PWM Mode Setting Procedure

An example of the complementary PWM mode setting procedure is shown in Figure 10.38.

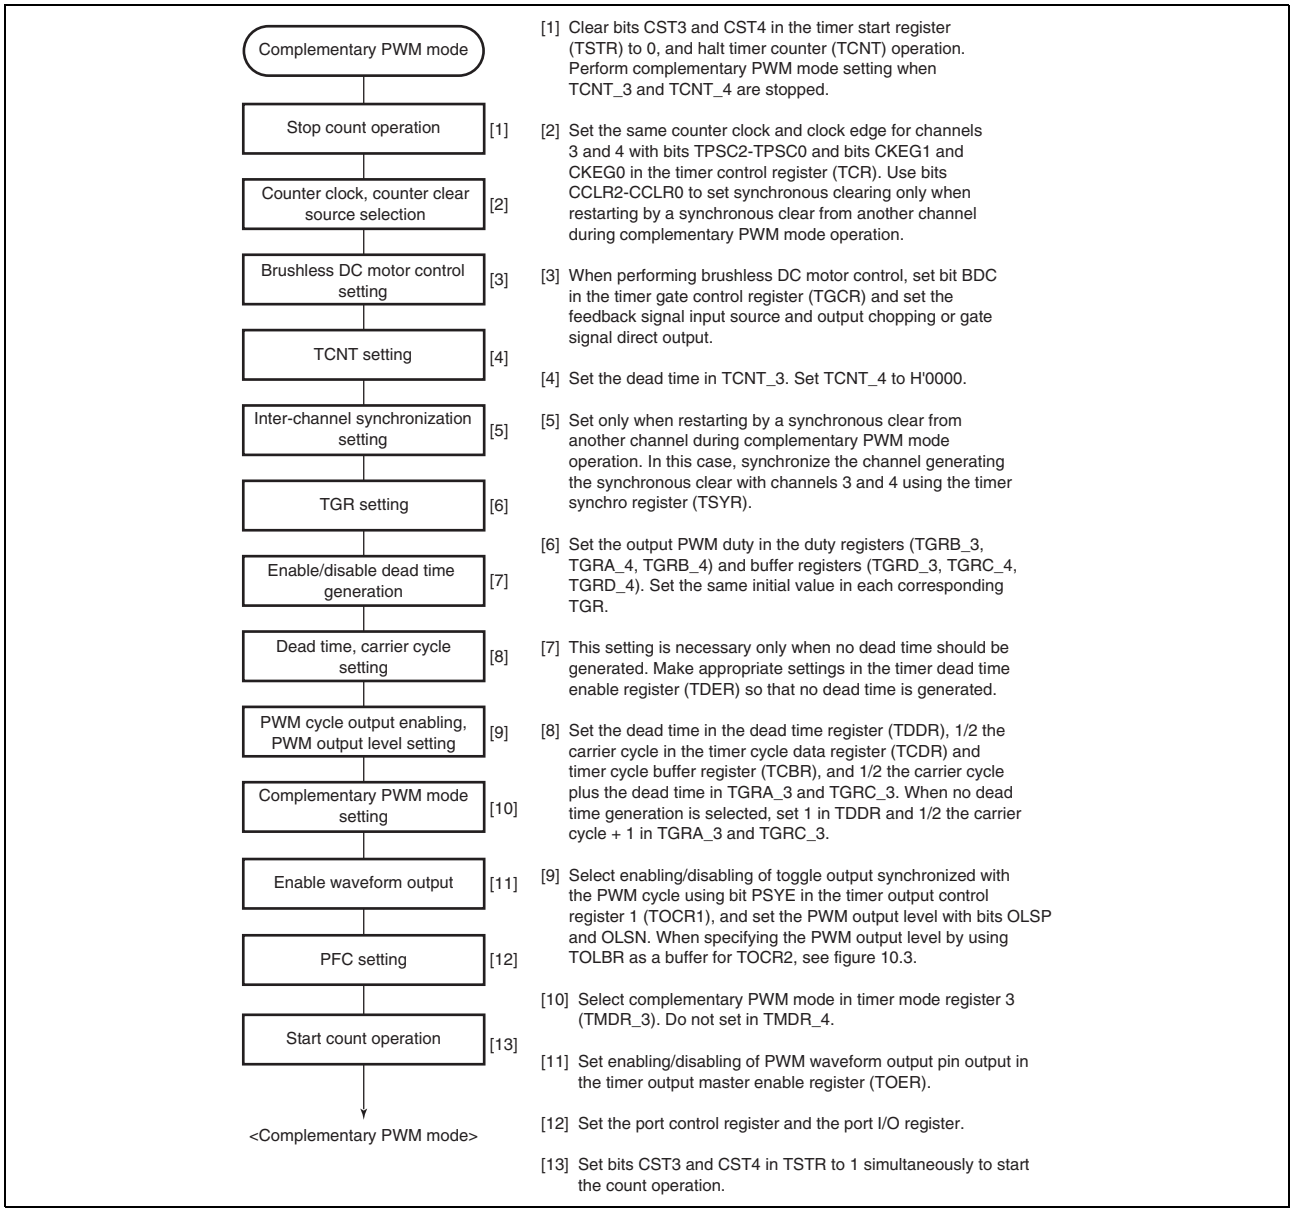

Figure 10.38 Example of Complementary PWM Mode Setting Procedure

(2) Outline of Complementary PWM Mode Operation

In complementary PWM mode, 6-phase PWM output is possible. Figure 10.39 illustrates counter operation in complementary PWM mode, and Figure 10.40 shows an example of complementary PWM mode operation.

(a) Counter Operation

In complementary PWM mode, three counters—TCNT_3, TCNT_4, and TCNTS—perform up/down-count operations.

TCNT_3 is automatically initialized to the value set in TDDR when complementary PWM mode is selected and the CST bit in TSTR is 0.

When the CST bit is set to 1, TCNT_3 counts up to the value set in TGRA_3, then switches to down-counting when it matches TGRA_3. When the TCNT_3 value matches TDDR, the counter switches to up-counting, and the operation is repeated in this way.

TCNT_4 is initialized to H'0000.

When the CST bit is set to 1, TCNT_4 counts up in synchronization with TCNT_3, and switches to down-counting when it matches TCDR. On reaching H'0000, TCNT_4 switches to up-counting, and the operation is repeated in this way.

TCNTS is a read-only counter. It need not be initialized.

When TCNT_3 matches TCDR during TCNT_3 and TCNT_4 up/down-counting, down-counting is started, and when TCNTS matches TCDR, the operation switches to up-counting. When TCNTS matches TGRA_3, it is cleared to H'0000. When TCNT_4 matches TDDR during TCNT_3 and TCNT_4 down-counting, up-counting is started, and when TCNTS matches TDDR, the operation switches to down-counting. When TCNTS reaches H'0000, it is set with the value in TGRA_3.

TCNTS is compared with the compare register and temporary register in which the PWM duty is set during the count operation only.

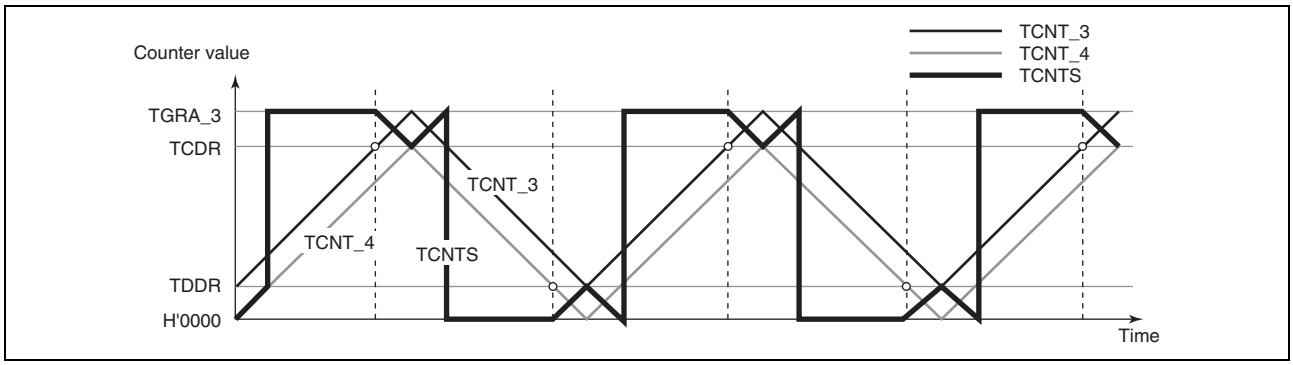

Figure 10.39 Complementary PWM Mode Counter Operation

(b) Register Operation

In complementary PWM mode, nine registers are used, comprising compare registers, buffer registers, and temporary registers. Figure 10.40 shows an example of complementary PWM mode operation.

The registers which are constantly compared with the counters to perform PWM output are TGRB_3, TGRA_4, and TGRB_4. When these registers match the counter, the value set in bits OLSN and OLSP in the timer output control register (TOCR) is output.

The buffer registers for these compare registers are TGRD_3, TGRC_4, and TGRD_4.

Between a buffer register and compare register there is a temporary register. The temporary registers cannot be accessed by the CPU.

Data in a compare register is changed by writing the new data to the corresponding buffer register. The buffer registers can be read or written at any time.

The data written to a buffer register is constantly transferred to the temporary register in the Ta interval. Data is not transferred to the temporary register in the Tb interval. Data written to a buffer register in this interval is transferred to the temporary register at the end of the Tb interval.

The value transferred to a temporary register is transferred to the compare register when TCNTS for which the Tb interval ends matches TGRA_3 when counting up, or H'0000 when counting down. The timing for transfer from the temporary register to the compare register can be selected with bits MD3 to MD0 in the timer mode register (TMDR). Figure 10.40 shows an example in which the mode is selected in which the change is made in the trough.

In the Tb interval (Tb1 in Figure 10.40) in which data transfer to the temporary register is not performed, the temporary register has the same function as the compare register, and is compared with the counter. In this interval, therefore, there are two compare match registers for one-phase output, with the compare register containing the pre-change data, and the temporary register containing the new data. In this interval, the three counters—TCNT_3, TCNT_4, and TCNTS—and two registers—compare register and temporary register—are compared, and PWM output controlled accordingly.

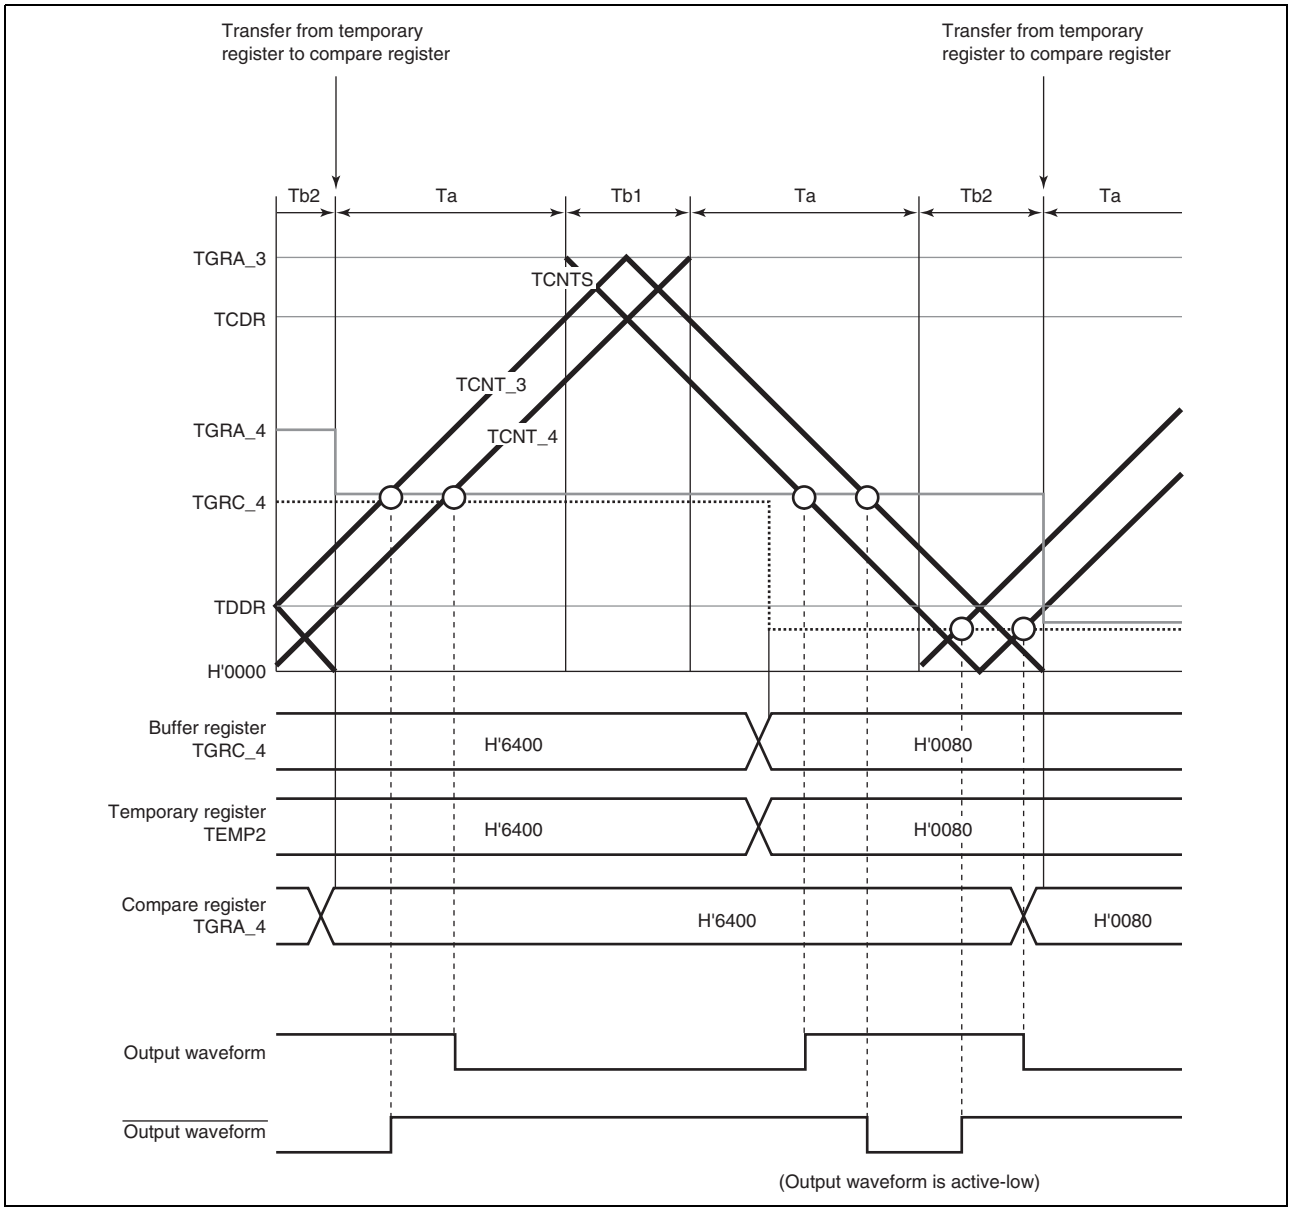

Figure 10.40 Example of Complementary PWM Mode Operation

(c) Initialization

In complementary PWM mode, there are six registers that must be initialized. In addition, there is a register that specifies whether to generate dead time (it should be used only when dead time generation should be disabled).

Before setting complementary PWM mode with bits MD3 to MD0 in the timer mode register (TMDR), the following initial register values must be set.

TGRC_3 operates as the buffer register for TGRA_3, and should be set with 1/2 the PWM carrier cycle + dead time Td. The timer cycle buffer register (TCBR) operates as the buffer register for the timer cycle data register (TCDR), and should be set with 1/2 the PWM carrier cycle. Set dead time Td in the timer dead time data register (TDDR).

When dead time is not needed, the TDER bit in the timer dead time enable register (TDER) should be cleared to 0, TGRC_3 and TGRA_3 should be set to 1/2 the PWM carrier cycle + 1, and TDDR should be set to 1.

Set the respective initial PWM duty values in buffer registers TGRD_3, TGRC_4, and TGRD_4.

The values set in the five buffer registers excluding TDDR are transferred simultaneously to the corresponding compare registers when complementary PWM mode is set.

Set TCNT_4 to H'0000 before setting complementary PWM mode.

Table 10.54 Registers and Counters Requiring Initialization

Register/Counter	Set Value
TGRC_3	1/2 PWM carrier cycle + dead time Td (1/2 PWM carrier cycle + 1 when dead time generation is disabled by TDER)
TDDR	Dead time Td (1 when dead time generation is disabled by TDER)
TCBR	1/2 PWM carrier cycle
TGRD_3, TGRC_4, TGRD_4	Initial PWM duty value for each phase
TCNT_4	H'0000

Note: The TGRC_3 set value must be the sum of 1/2 the PWM carrier cycle set in TCBR and dead time Td set in TDDR. When dead time generation is disabled by TDER, TGRC_3 must be set to 1/2 the PWM carrier cycle + 1.

(d) PWM Output Level Setting

In complementary PWM mode, the PWM pulse output level is set with bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1P to OLS3P and OLS1N to OLS3N in timer output control register 2 (TOCR2).

The output level can be set for each of the three positive phases and three negative phases of 6-phase output.

Complementary PWM mode should be cleared before setting or changing output levels.

(e) Dead Time Setting

In complementary PWM mode, PWM pulses are output with a non-overlapping relationship between the positive and negative phases. This non-overlap time is called the dead time.

The non-overlap time is set in the timer dead time data register (TDDR). The value set in TDDR is used as the TCNT_3 counter start value, and creates non-overlap between TCNT_3 and TCNT_4. Complementary PWM mode should be cleared before changing the contents of TDDR.

(f) Dead Time Suppressing

Dead time generation is suppressed by clearing the TDER bit in the timer dead time enable register (TDER) to 0. TDER can be cleared to 0 only when 0 is written to it after reading TDER = 1.

TGRA_3 and TGRC_3 should be set to 1/2 PWM carrier cycle + 1 and the timer dead time data register (TDDR) should be set to 1.

By the above settings, PWM waveforms without dead time can be obtained. Figure 10.41 shows an example of operation without dead time.

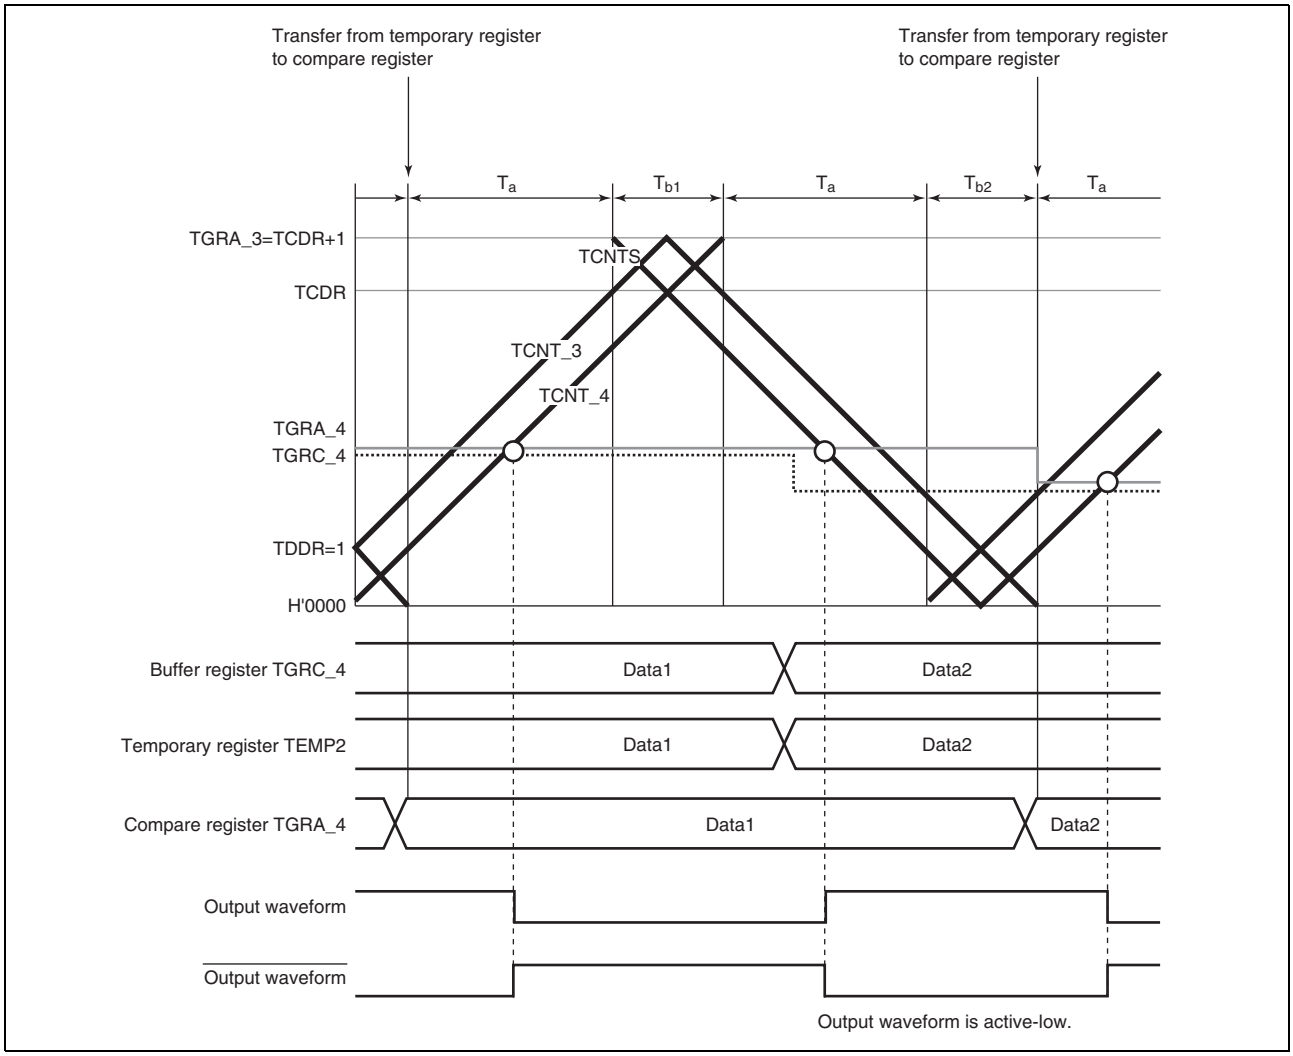

Figure 10.41 Example of Operation without Dead Time

(g) PWM Cycle Setting

In complementary PWM mode, the PWM pulse cycle is set in two registers—TGRA_3, in which the TCNT_3 upper limit value is set, and TCDR, in which the TCNT_4 upper limit value is set. The settings should be made so as to achieve the following relationship between these two registers:

With dead time: TGRA_3 setting = TCDR setting + TDDR setting
TCDR setting > (twice the TDDR setting) + 2
Without dead time: TGRA_3 setting = TCDR setting + 1
TCDR setting > 4

The TGRA_3 and TCDR settings are made by setting the values in buffer registers TGRC_3 and TCBR. The values set in TGRC_3 and TCBR are transferred simultaneously to TGRA_3 and TCDR in accordance with the transfer timing selected with bits MD3 to MD0 in the timer mode register (TMDR).

The updated PWM cycle is reflected from the next cycle when the data update is performed at the crest, and from the current cycle when performed in the trough. Figure 10.42 illustrates the operation when the PWM cycle is updated at the crest.

See (h) Register Data Updating, for the method of updating the data in each buffer register.

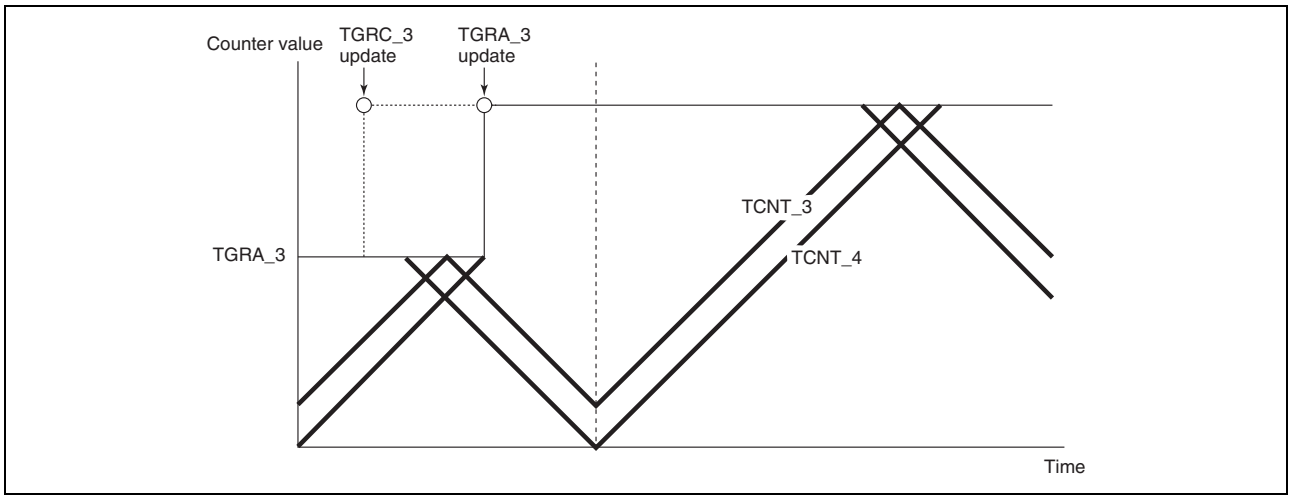

Figure 10.42 Example of PWM Cycle Updating

(h) Register Data Updating

In complementary PWM mode, the buffer register is used to update the data in a compare register. The update data can be written to the buffer register at any time. There are five PWM duty and carrier cycle registers that have buffer registers and can be updated during operation.

There is a temporary register between each of these registers and its buffer register. When subcounter TCNTS is not counting, if buffer register data is updated, the temporary register value is also rewritten. Transfer is not performed from buffer registers to temporary registers when TCNTS is counting; in this case, the value written to a buffer register is transferred after TCNTS halts.

The temporary register value is transferred to the compare register at the data update timing set with bits MD3 to MD0 in the timer mode register (TMDR). Figure 10.43 shows an example of data updating in complementary PWM mode. This example shows the mode in which data updating is performed at both the counter crest and trough.

When rewriting buffer register data, a write to TGRD_4 must be performed at the end of the update. Data transfer from the buffer registers to the temporary registers is performed simultaneously for all five registers after the write to TGRD_4.

A write to TGRD_4 must be performed after writing data to the registers to be updated, even when not updating all five registers, or when updating the TGRD_4 data. In this case, the data written to TGRD_4 should be the same as the data prior to the write operation.

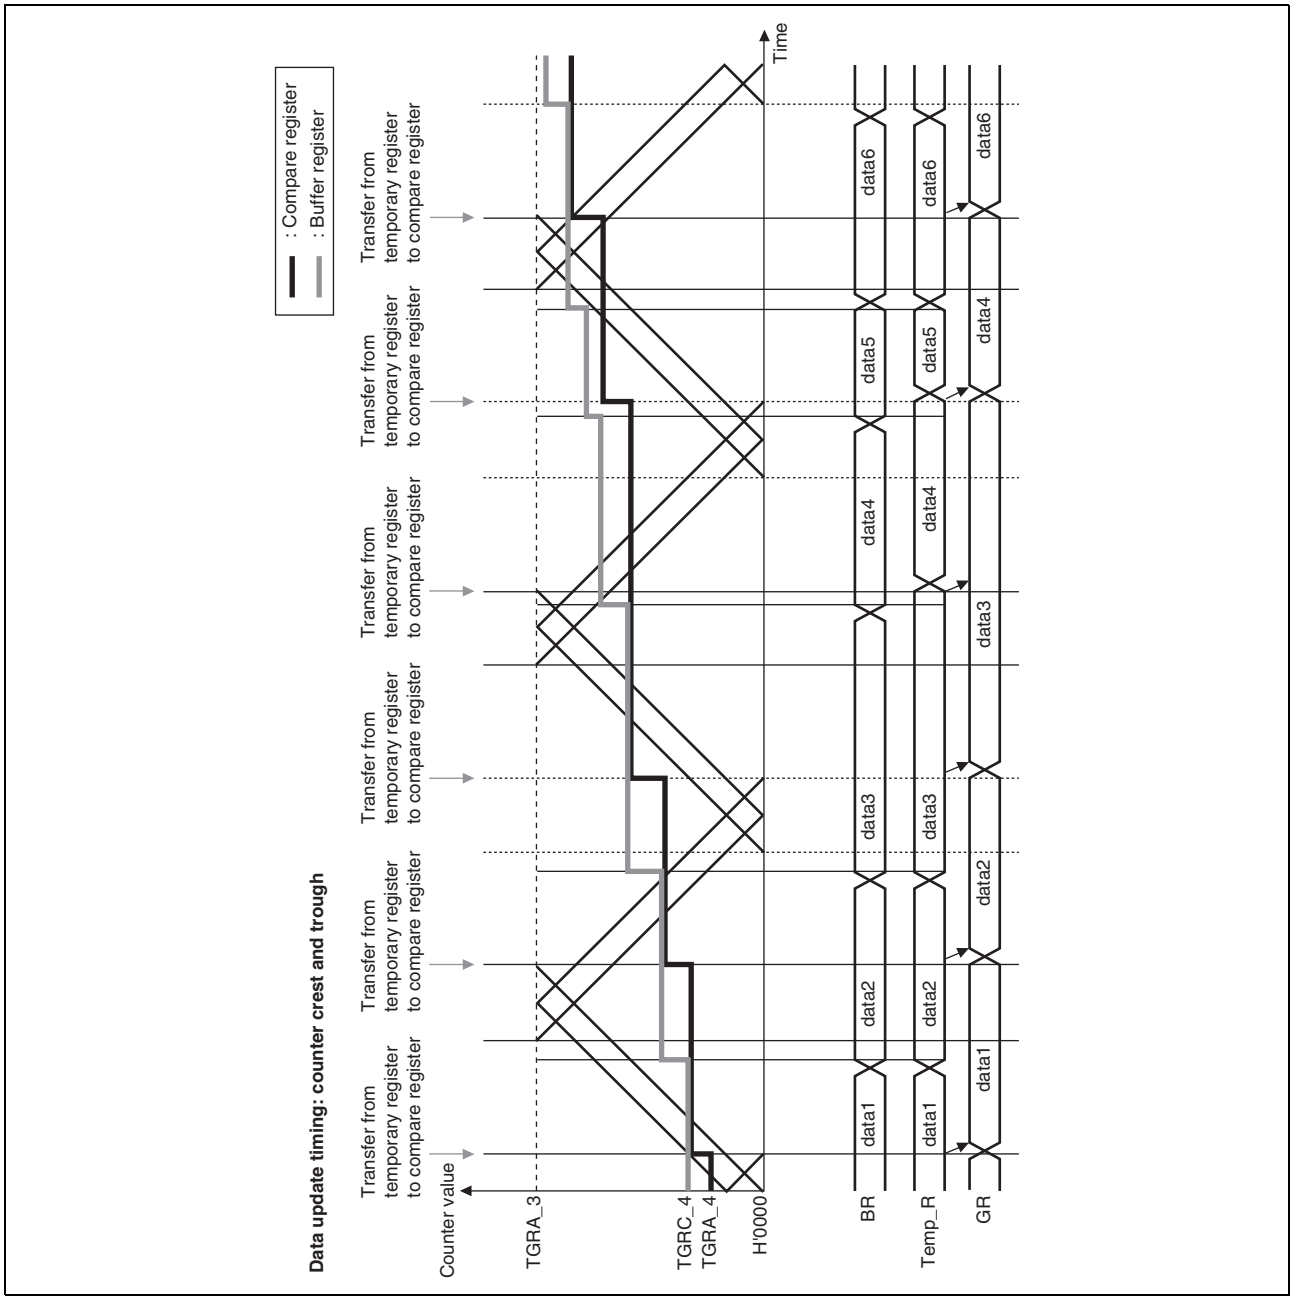

Figure 10.43 Example of Data Update in Complementary PWM Mode

(i) Initial Output in Complementary PWM Mode

In complementary PWM mode, the initial output is determined by the setting of bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1N to OLS3N and OLS1P to OLS3P in timer output control register 2 (TOCR2).

This initial output is the PWM pulse non-active level, and is output from when complementary PWM mode is set with the timer mode register (TMDR) until TCNT_4 exceeds the value set in the dead time register (TDDR). Figure 10.44 shows an example of the initial output in complementary PWM mode.

An example of the waveform when the initial PWM duty value is smaller than the TDDR value is shown in Figure 10.45.

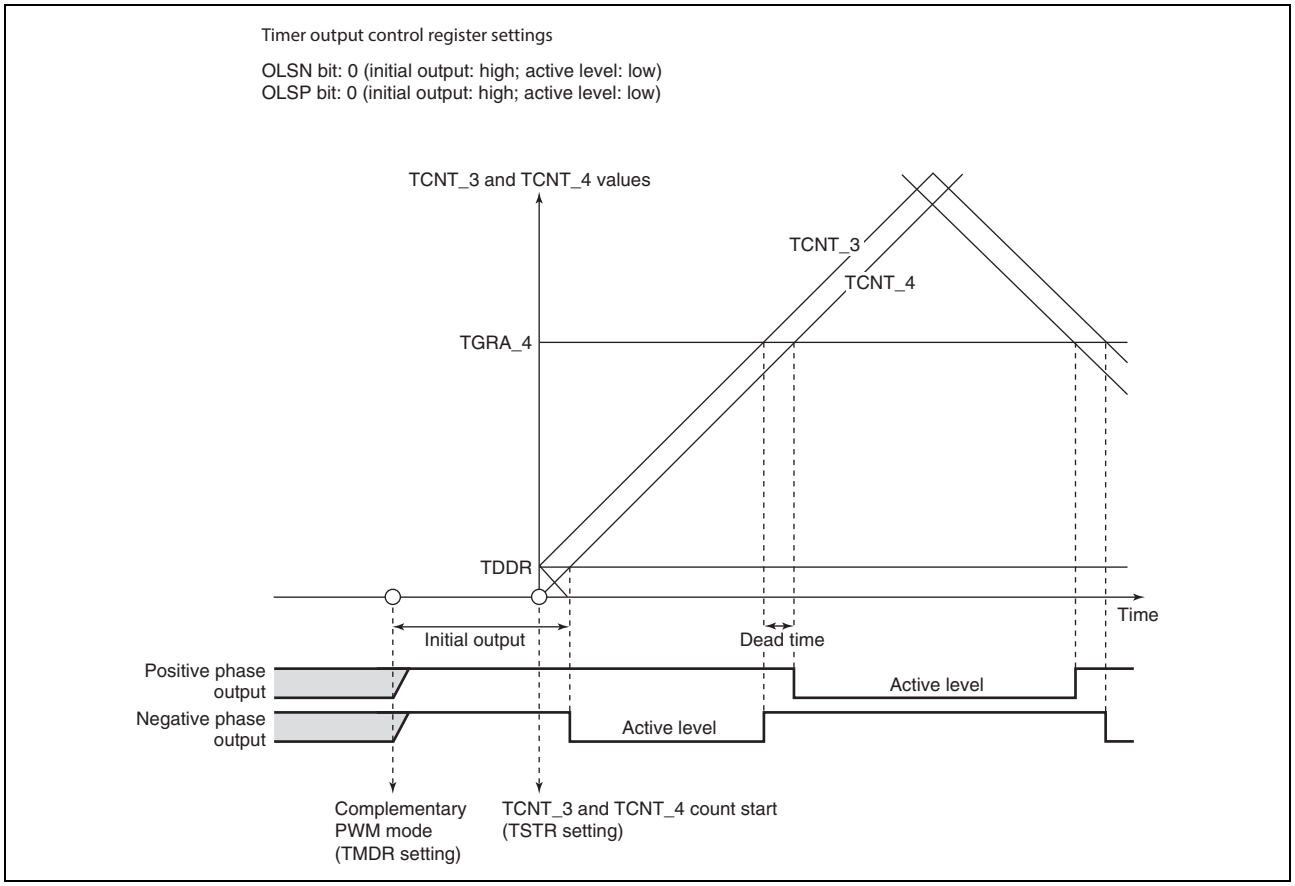

Figure 10.44 Example of Initial Output in Complementary PWM Mode (1)

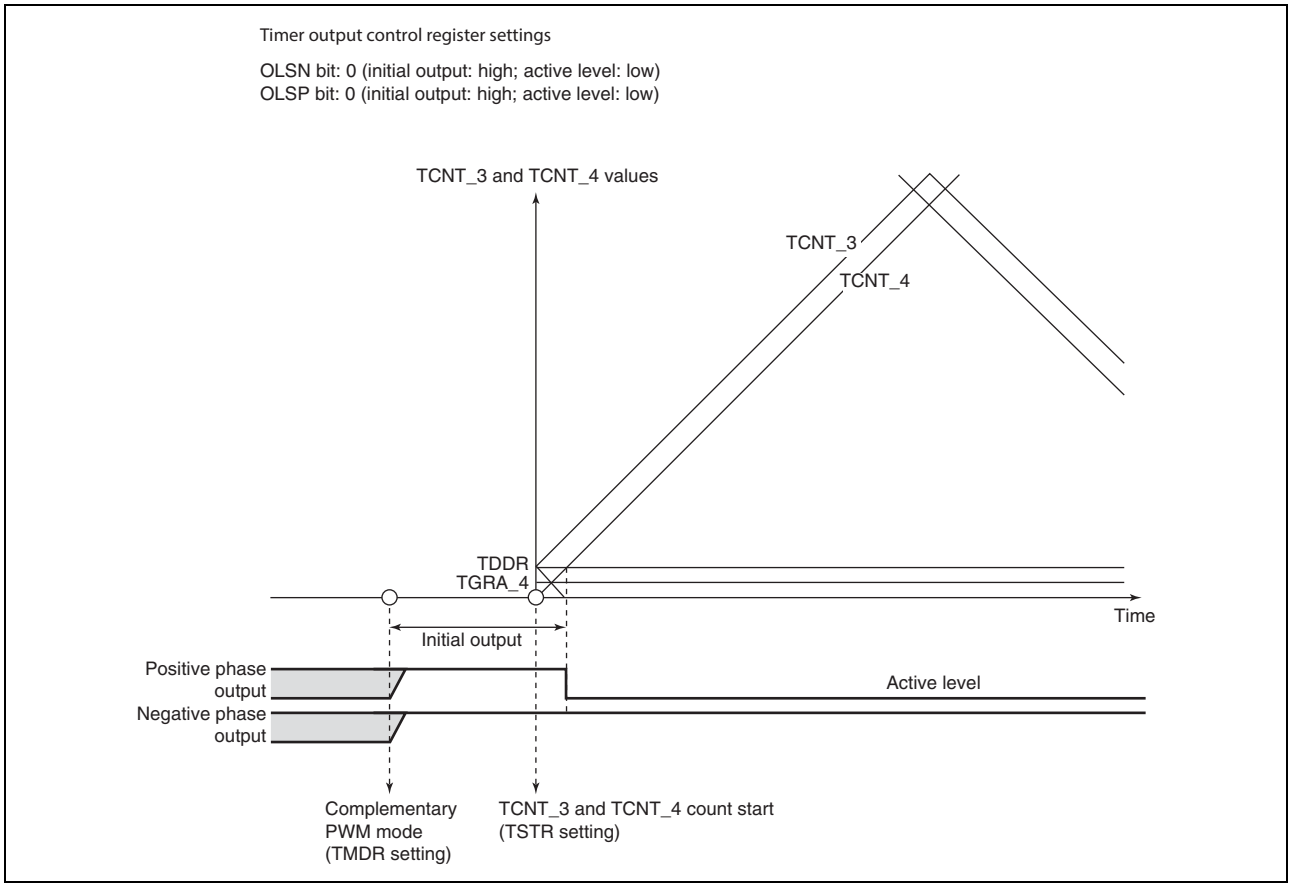

Figure 10.45 Example of Initial Output in Complementary PWM Mode (2)

(j) Complementary PWM Mode PWM Output Generation Method

In complementary PWM mode, 3-phase output is performed of PWM waveforms with a non-overlap time between the positive and negative phases. This non-overlap time is called the dead time.

A PWM waveform is generated by output of the output level selected in the timer output control register in the event of a compare-match between a counter and compare register. While TCNTS is counting, compare register and temporary register values are simultaneously compared to create consecutive PWM pulses from 0 to 100%. The relative timing of on and off compare-match occurrence may vary, but the compare-match that turns off each phase takes precedence to secure the dead time and ensure that the positive phase and negative phase on times do not overlap. Figure 10.46 to Figure 10.48 show examples of waveform generation in complementary PWM mode.

The positive phase/negative phase off timing is generated by a compare-match with the solid-line counter, and the on timing by a compare-match with the dotted-line counter operating with a delay of the dead time behind the solid-line counter. In the T1 period, compare-match **a** that turns off the negative phase has the highest priority, and compare-matches occurring prior to **a** are ignored. In the T2 period, compare-match **c** that turns off the positive phase has the highest priority, and compare-matches occurring prior to **c** are ignored.

In normal cases, compare-matches occur in the order **a** → **b** → **c** → **d** (or **c** → **d** → **a'** → **b'**), as shown in figure 10.46.

If compare-matches deviate from the **a** → **b** → **c** → **d** order, since the time for which the negative phase is off is less than twice the dead time, the figure shows the positive phase is not being turned on. If compare-matches deviate from the **c** → **d** → **a'** → **b'** order, since the time for which the positive phase is off is less than twice the dead time, the figure shows the negative phase is not being turned on.

If compare-match **c** occurs first following compare-match **a**, as shown in Figure 10.47, compare-match **b** is ignored, and the negative phase is turned on by compare-match **d**. This is because turning off of the positive phase has priority due to the occurrence of compare-match **c** (positive phase off timing) before compare-match **b** (positive phase on timing) (consequently, the waveform does not change since the positive phase goes from off to off).

Similarly, in the example in Figure 10.48, compare-match **a'** with the new data in the temporary register occurs before compare-match **c**, but other compare-matches occurring up to **c**, which turns off the positive phase, are ignored. As a result, the negative phase is not turned on.

Thus, in complementary PWM mode, compare-matches at turn-off timings take precedence, and turn-on timing compare-matches that occur before a turn-off timing compare-match are ignored.

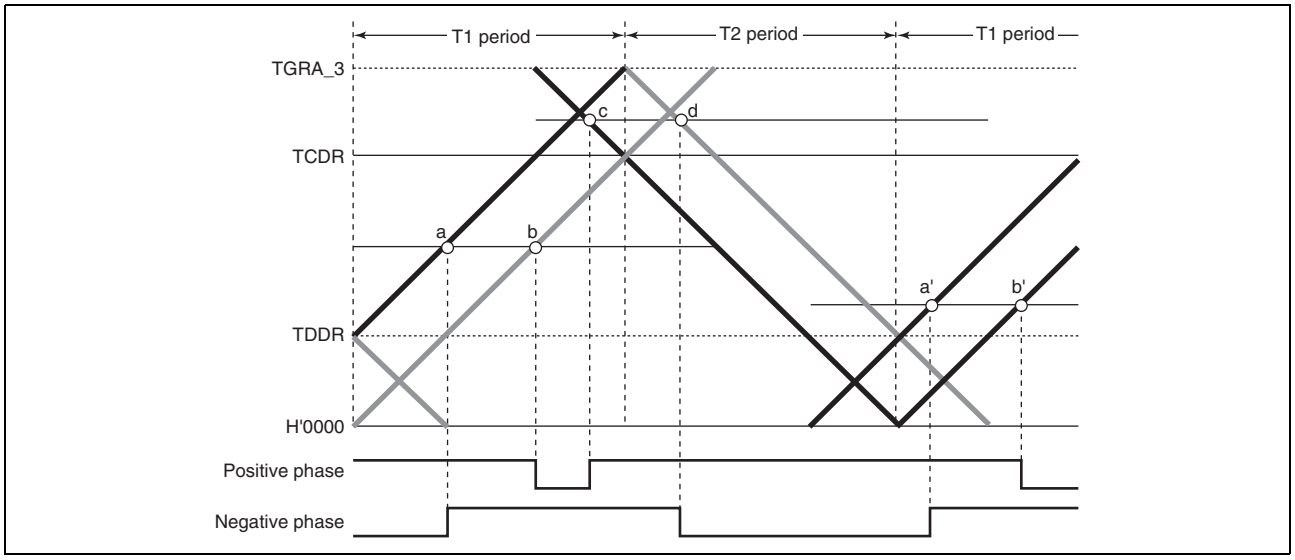

Figure 10.46 Example of Complementary PWM Mode Waveform Output (1)

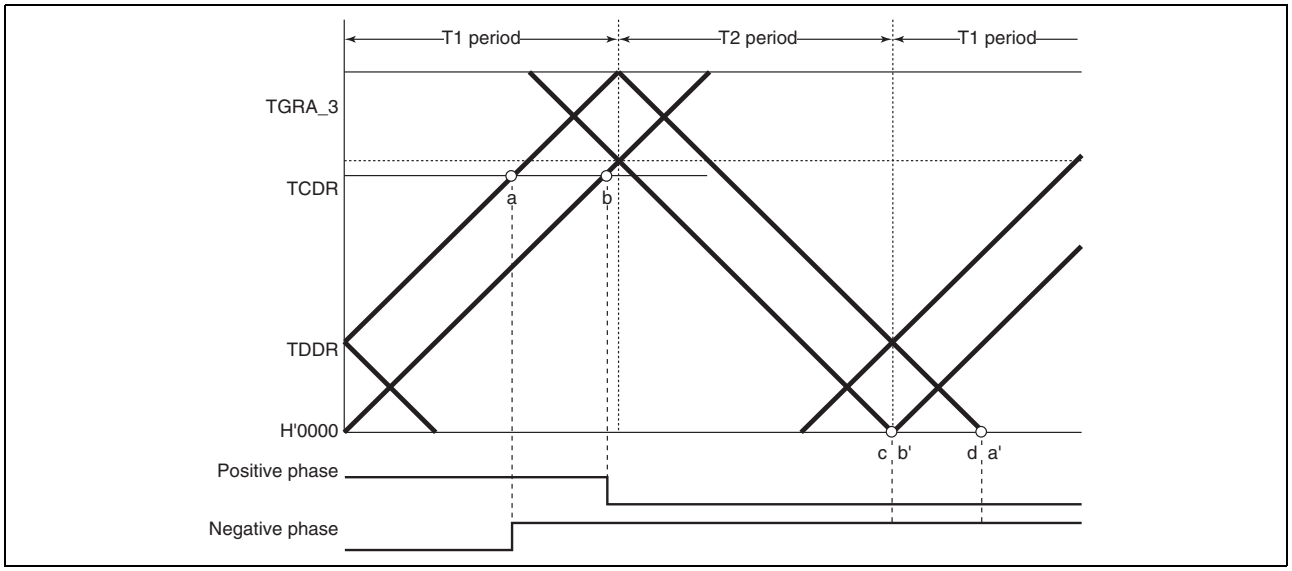

Figure 10.52 Example of Complementary PWM Mode 0% and 100% Waveform Output (4)

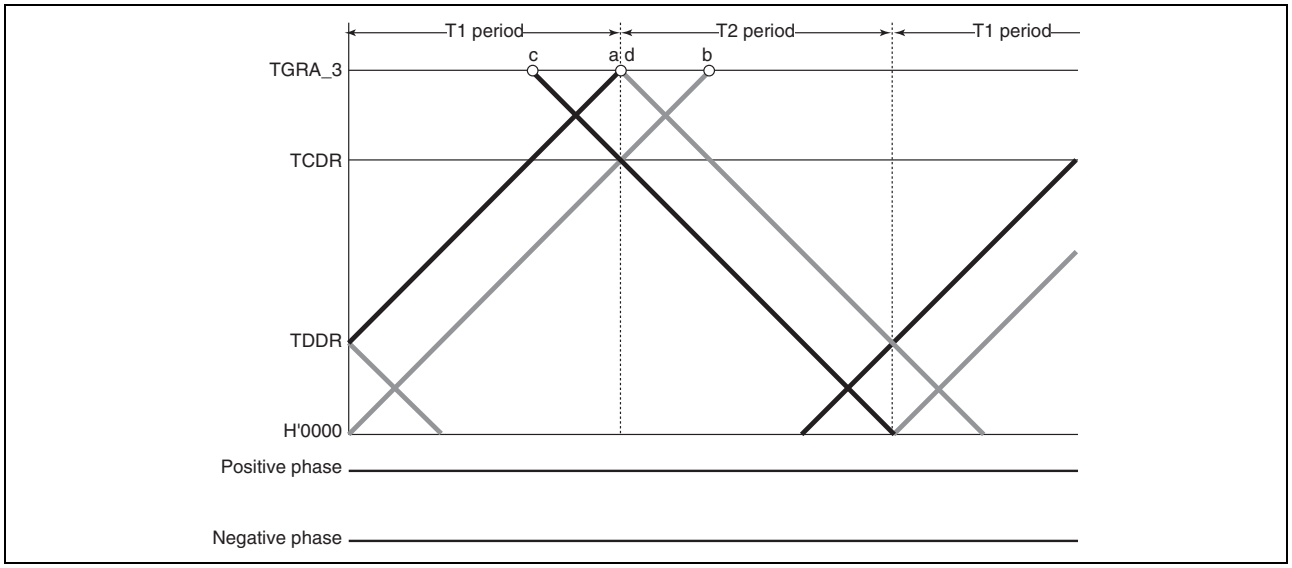

Figure 10.53 Example of Complementary PWM Mode 0% and 100% Waveform Output (5)

(k) Complementary PWM Mode 0% and 100% Duty Output

In complementary PWM mode, 0% and 100% duty cycles can be output as required. Figure 10.49 to Figure 10.53 show output examples.

100% duty output is performed when the compare register value is set to H'0000. The waveform in this case has a positive phase with a 100% on-state. 0% duty output is performed when the compare register value is set to the same value as TGRA_3. The waveform in this case has a positive phase with a 100% off-state.

On and off compare-matches occur simultaneously, but if a turn-on compare-match and turn-off compare-match for the same phase occur simultaneously, both compare-matches are ignored and the waveform does not change.

(l) Toggle Output Synchronized with PWM Cycle

In complementary PWM mode, toggle output can be performed in synchronization with the PWM carrier cycle by setting the PSYE bit to 1 in the timer output control register (TOCR). An example of a toggle output waveform is shown in Figure 10.54.

This output is toggled by a compare-match between TCNT_3 and TGRA_3 and a compare-match between TCNT_4 and H'0000.

The output pin for this toggle output is the TIOC3A pin. The initial output is 1.

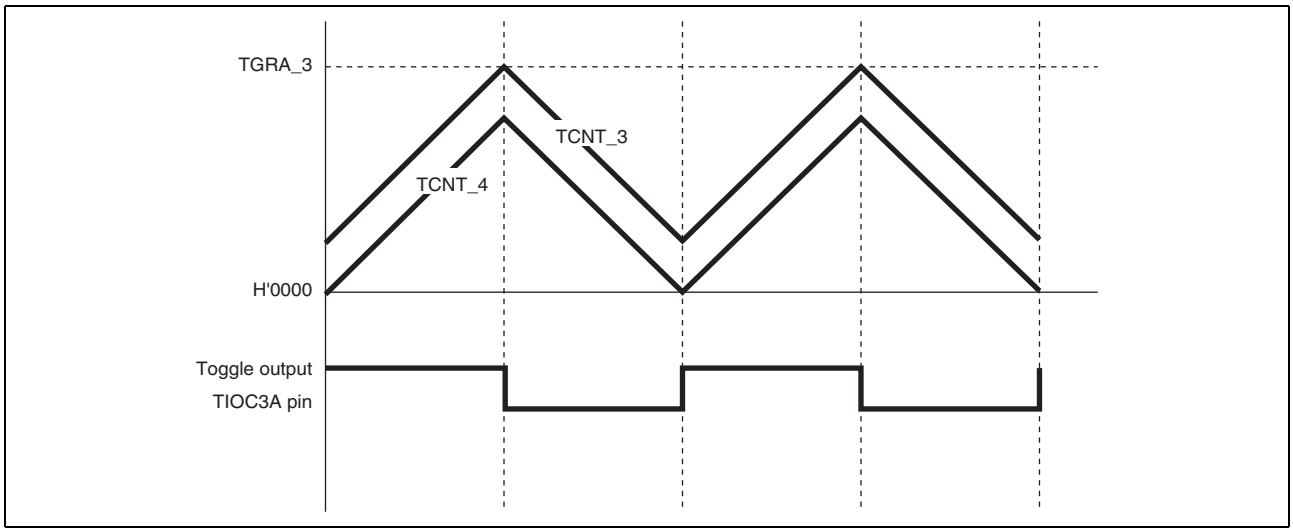

Figure 10.54 Example of Toggle Output Waveform Synchronized with PWM Output

(m) Counter Clearing by Another Channel

In complementary PWM mode, by setting a mode for synchronization with another channel by means of the timer synchronous register (TSYR), and selecting synchronous clearing with bits CCLR2 to CCLR0 in the timer control register (TCR), it is possible to have TCNT_3, TCNT_4, and TCNTS cleared by another channel.

Figure 10.55 illustrates the operation.

Use of this function enables counter clearing and restarting to be performed by means of an external signal.

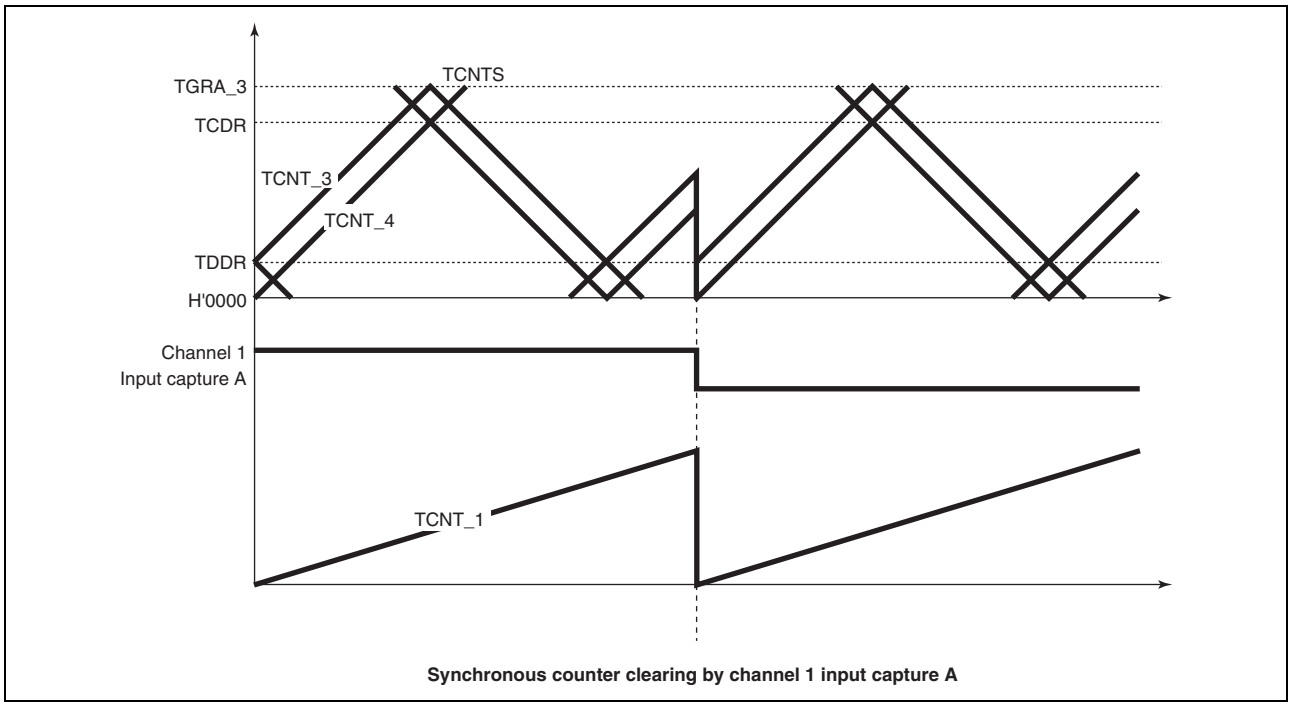

Figure 10.55 Counter Clearing Synchronized with Another Channel

(n) Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

Setting the WRE bit in TWCR to 1 suppresses initial output when synchronous counter clearing occurs in the Tb interval at the trough in complementary PWM mode and controls abrupt change in duty cycle at synchronous counter clearing.

Initial output suppression is applicable only when synchronous clearing occurs in the Tb interval at the trough as indicated by (10) or (11) in Figure 10.56. When synchronous clearing occurs outside that interval, the initial value specified by the OLS bits in TOCR is output. Even in the Tb interval at the trough, if synchronous clearing occurs in the initial value output period (indicated by (1) in Figure 10.56) immediately after the counters start operation, initial value output is not suppressed.

When using the initial output suppression function, make sure to set compare registers TGRB_3, TGRA_4, and TGRB_4 to a value twice or more the setting of dead time data register TDDR. If synchronous clearing occurs with the compare registers set to a value less than twice the setting of TDDR, the PWM output dead time may be too short (or nonexistent) or illegal active-level PWM negative-phase output may occur during the initial output suppression interval. For details, see section 10.7.23, Notes on Output Waveform Control During Synchronous Counter Clearing in Complementary PWM Mode.

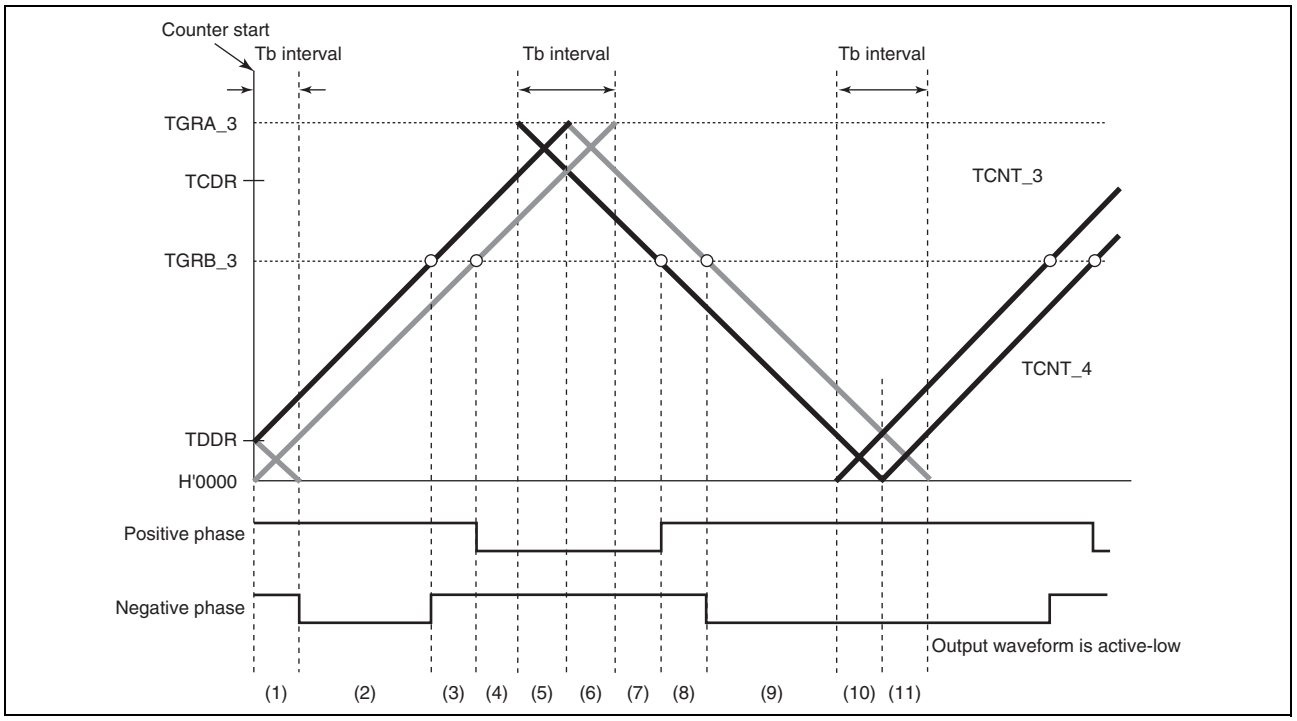

Figure 10.56 Timing for Synchronous Counter Clearing

- Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode
  An example of the procedure for setting output waveform control at synchronous counter clearing in complementary PWM mode is shown in Figure 10.57.

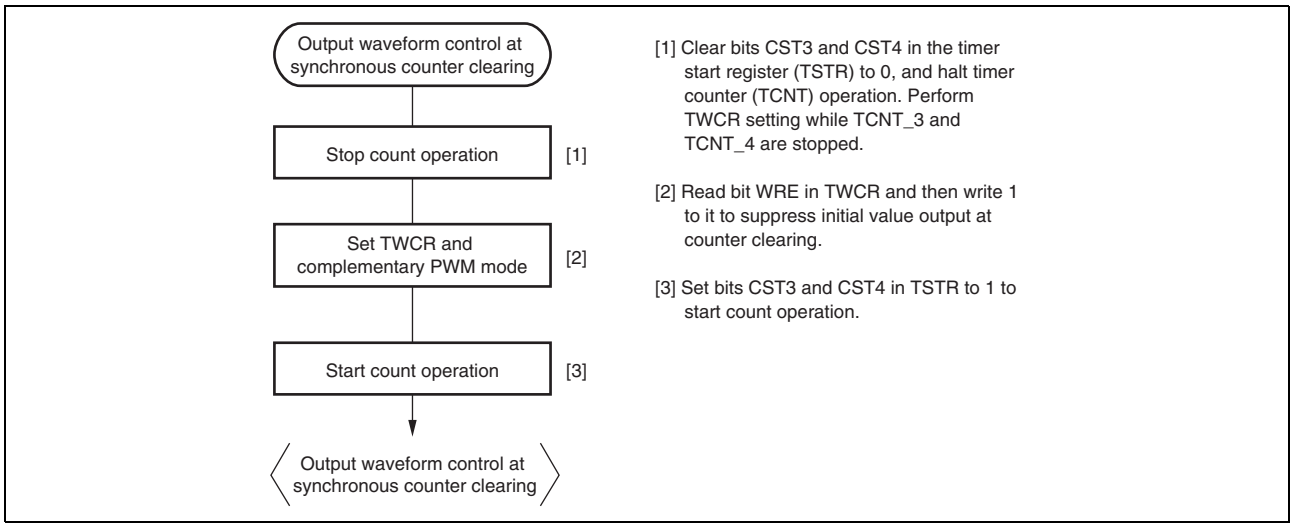

Figure 10.57 Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

- Examples of Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode
  Figure 10.58 to Figure 10.61 show examples of output waveform control in which this module operates in complementary PWM mode and synchronous counter clearing is generated while the WRE bit in TWCR is set to 1. In the examples shown in Figure 10.58 to Figure 10.61, synchronous counter clearing occurs at timing (3), (6), (8), and (11) shown in Figure 10.56, respectively.

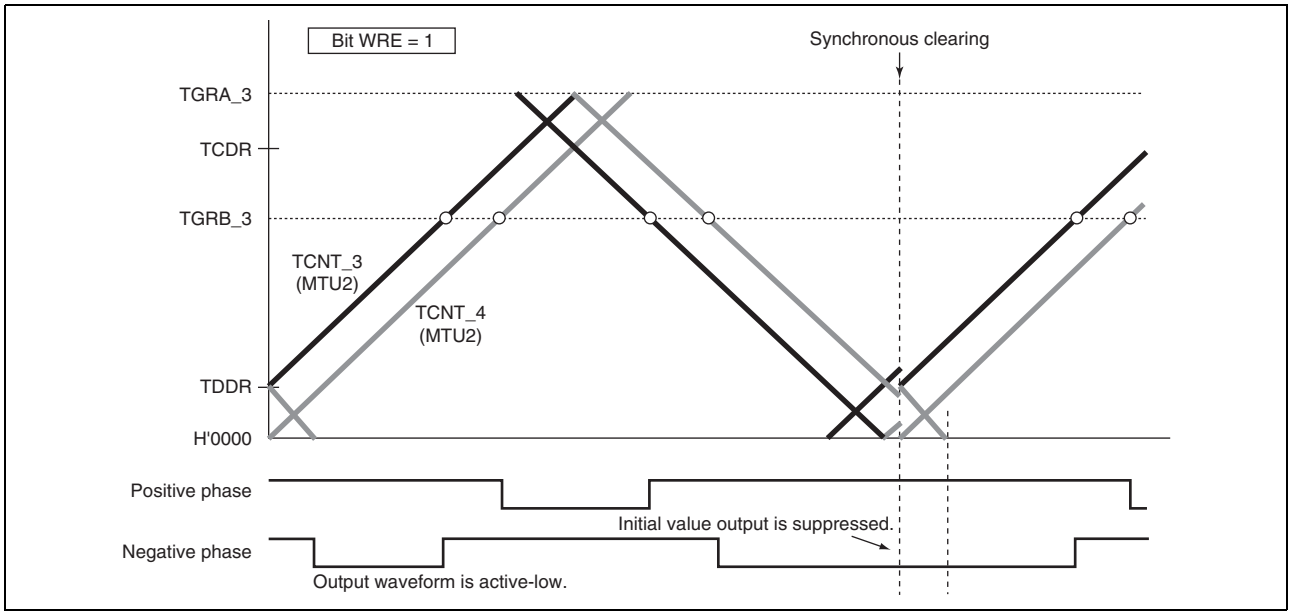

Figure 10.61 Example of Synchronous Clearing in Interval Tb at Trough (Timing (11) in Figure 10.56; Bit WRE of TWCR is 1)

(o) Counter Clearing by TGRA_3 Compare Match

In complementary PWM mode, by setting the CCE bit in the timer waveform control register (TWCR), it is possible to have TCNT_3, TCNT_4, and TCNTS cleared by TGRA_3 compare match.

Figure 10.62 illustrates an operation example.

Note 1. Use this function only in complementary PWM mode 1 (transfer at crest)
Note 2. Do not specify synchronous clearing by another channel (do not set the SYNC0 to SYNC4 bits in the timer synchronous register (TSYR) to 1).
Note 3. Do not set the PWM duty value to H'0000.
Note 4. Do not set the PSYE bit in timer output control register 1 (TOCR1) to 1.

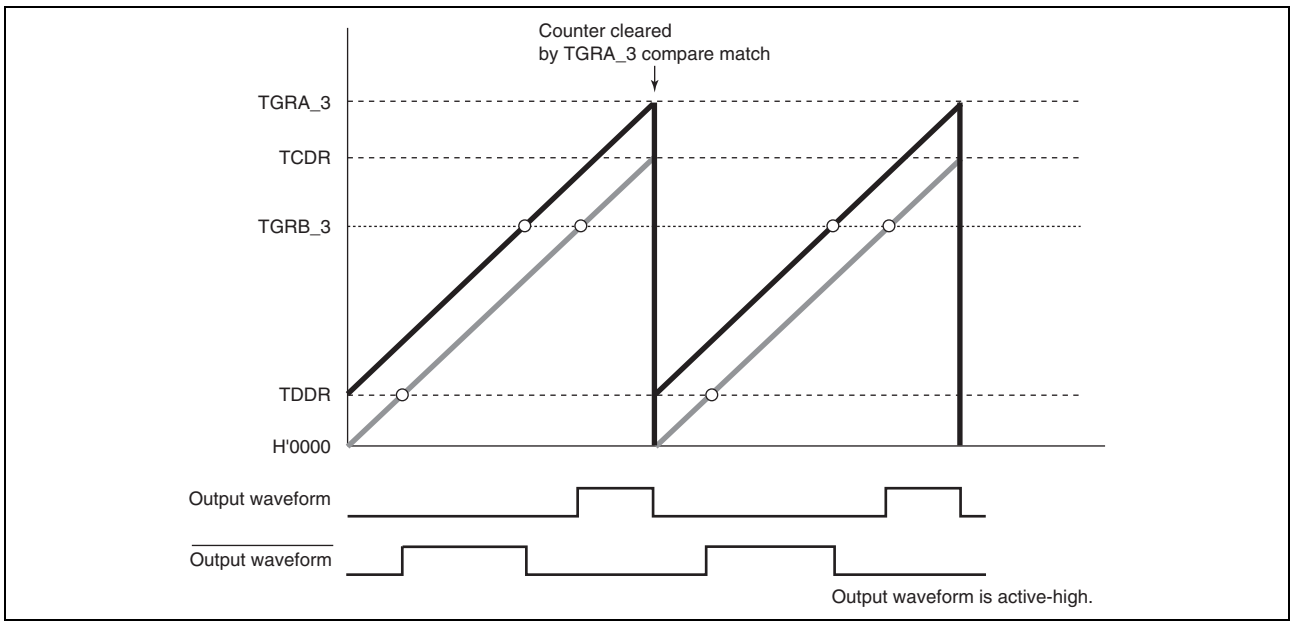

Figure 10.62 Example of Counter Clearing Operation by TGRA_3 Compare Match

(p) Example of AC Synchronous Motor (Brushless DC Motor) Drive Waveform Output

In complementary PWM mode, a brushless DC motor can easily be controlled using the timer gate control register (TGCR). Figure 10.63 to Figure 10.66 show examples of brushless DC motor drive waveforms created using TGCR.

When output phase switching for a 3-phase brushless DC motor is performed by means of external signals detected with a Hall element, etc., clear the FB bit in TGCR to 0. In this case, the external signals indicating the polarity position are input to channel 0 timer input pins TIOC0A, TIOC0B, and TIOC0C (set with the general I/O ports). When an edge is detected at pin TIOC0A, TIOC0B, or TIOC0C, the output on/off state is switched automatically.

When the FB bit is 1, the output on/off state is switched when the UF, VF, or WF bit in TGCR is cleared to 0 or set to 1. The drive waveforms are output from the complementary PWM mode 6-phase output pins. With this 6-phase output, in the case of on output, it is possible to use complementary PWM mode output and perform chopping output by setting the N bit or P bit to 1. When the N bit or P bit is 0, level output is selected.

The 6-phase output active level (on output level) can be set with the OLSN and OLSP bits in the timer output control register (TOCR) regardless of the setting of the N and P bits.

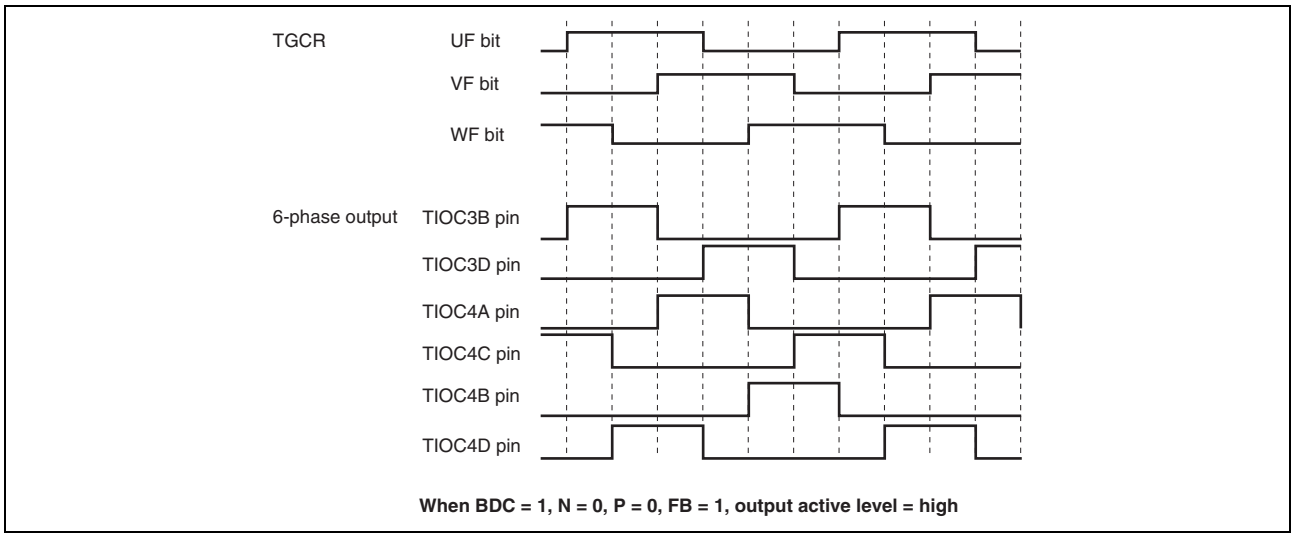

Figure 10.65 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (1)

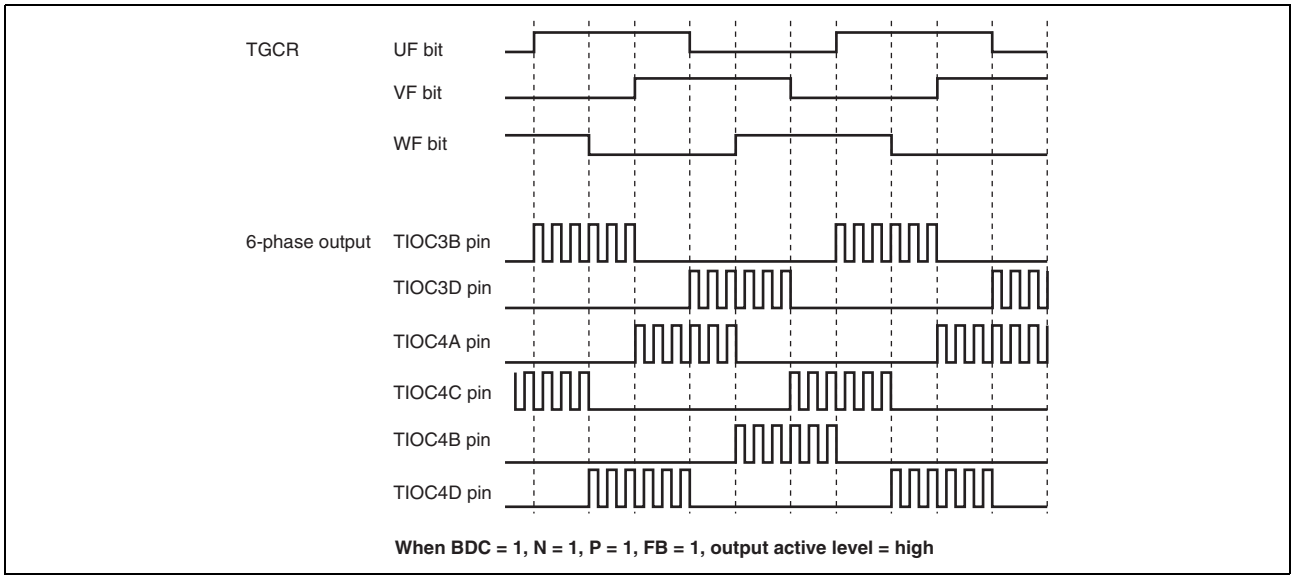

Figure 10.66 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (2)

(q) A/D Converter Start Request Setting

In complementary PWM mode, an A/D converter start request can be issued using a TGRA_3 compare-match, TCNT_4 underflow (trough), or compare-match on a channel other than channels 3 and 4.

When start requests using a TGRA_3 compare-match are specified, A/D conversion can be started at the crest of the TCNT_3 count.

A/D converter start requests can be set by setting the TTGE bit to 1 in the timer interrupt enable register (TIER). To issue an A/D converter start request at a TCNT_4 underflow (trough), set the TTGE2 bit in TIER_4 to 1.

(3) Interrupt Skipping in Complementary PWM Mode

Interrupts TGIA_3 (at the crest) and TCIV_4 (at the trough) in channels 3 and 4 can be skipped up to seven times by making settings in the timer interrupt skipping set register (TITCR).

Transfers from a buffer register to a temporary register or a compare register can be skipped in coordination with interrupt skipping by making settings in the timer buffer transfer register (TBTER). For the linkage with buffer registers, refer to description (c), Buffer Transfer Control Linked with Interrupt Skipping, below.

A/D converter start requests generated by the A/D converter start request delaying function can also be skipped in coordination with interrupt skipping by making settings in the timer A/D converter request control register (TADCR). For the linkage with the A/D converter start request delaying function, refer to section 10.4.9, A/D Converter Start Request Delaying Function.

The setting of the timer interrupt skipping setting register (TITCR) must be done while the TGIA_3 and TCIV_4 interrupt requests are disabled by the settings of TIER_3 and TIER_4 along with under the conditions in which TGFA_3 and TCFV_4 flag settings by compare match never occur. Before changing the skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter.

(a) Example of Interrupt Skipping Operation Setting Procedure

Figure 10.67 shows an example of the interrupt skipping operation setting procedure. Figure 10.68 shows the periods during which interrupt skipping count can be changed.

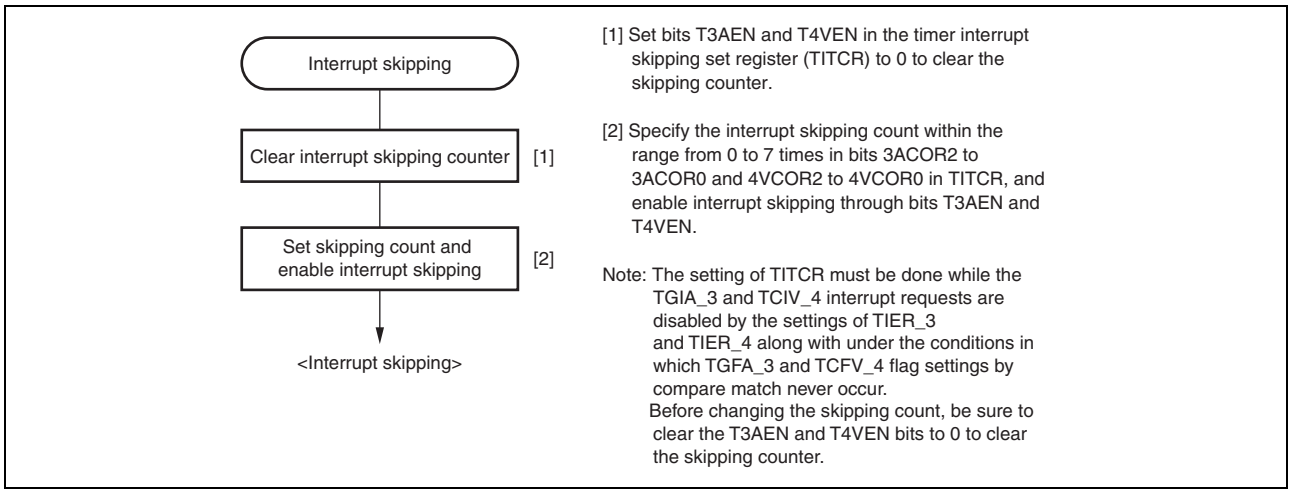

Figure 10.67 Example of Interrupt Skipping Operation Setting Procedure

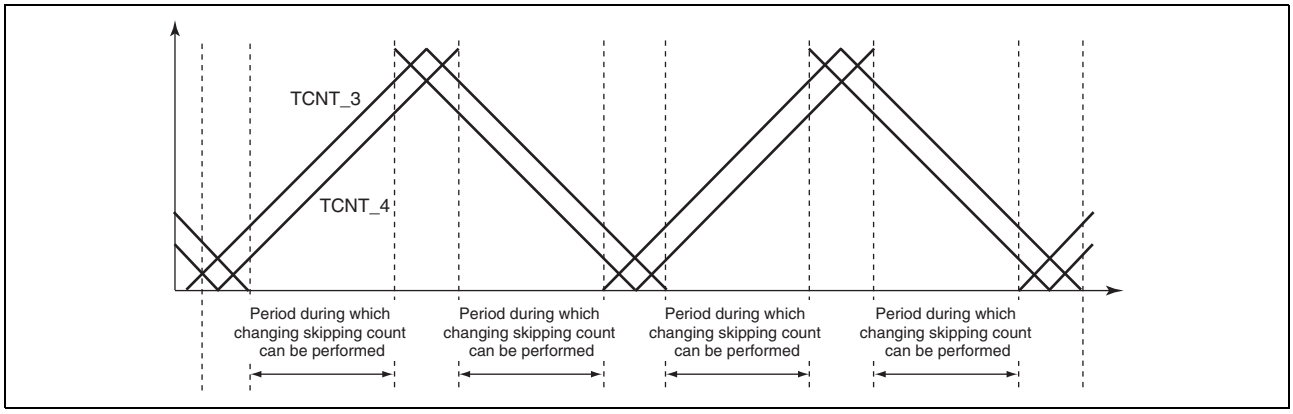

Figure 10.68 Periods during which Interrupt Skipping Count can be Changed

(b) Example of Interrupt Skipping Operation

Figure 10.69 shows an example of TGIA_3 interrupt skipping in which the interrupt skipping count is set to three by the 3ACOR bit and the T3AEN bit is set to 1 in the timer interrupt skipping set register (TITCR).

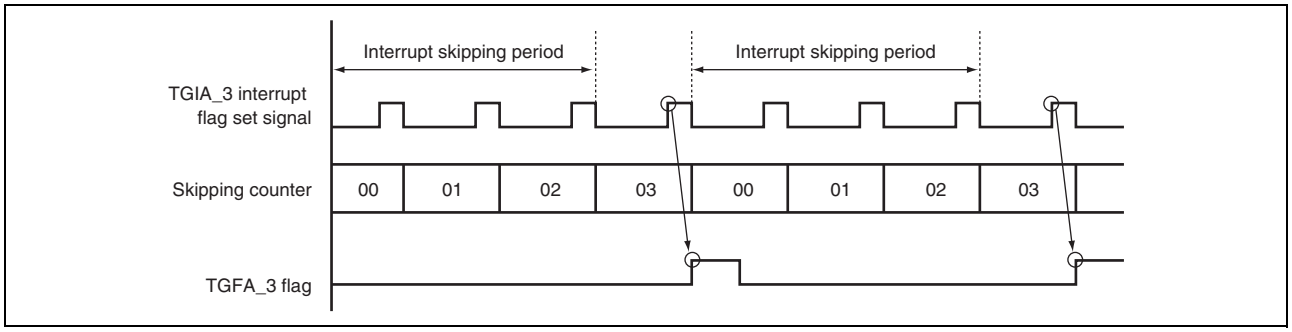

Figure 10.69 Example of Interrupt Skipping Operation

(c) Buffer Transfer Control Linked with Interrupt Skipping

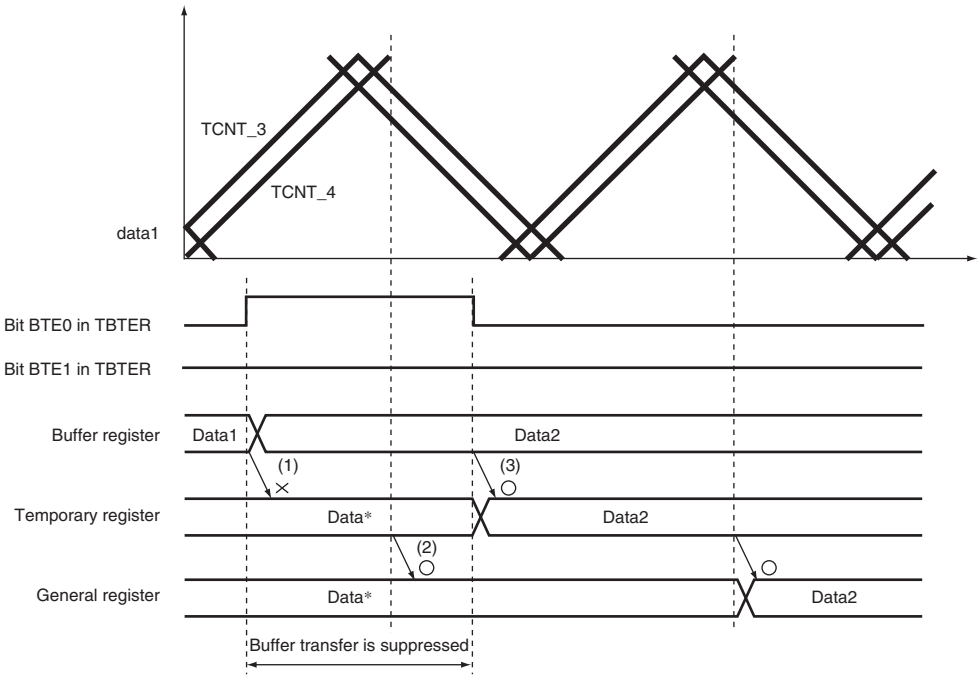
In complementary PWM mode, whether to transfer data from a buffer register to a temporary register and whether to link the transfer with interrupt skipping can be specified with the BTE1 and BTE0 bits in the timer buffer transfer set register (TBTER).

Figure 10.70 shows an example of operation when buffer transfer is suppressed (BTE1 = 0 and BTE0 = 1). While this setting is valid, data is not transferred from the buffer register to the temporary register.

Figure 10.71 shows an example of operation when buffer transfer is linked with interrupt skipping (BTE1 = 1 and BET0 = 0). While this setting is valid, data is not transferred from the buffer register to the temporary register outside the buffer transfer-enabled period. Depending on the rewrite timing from the interrupt generation to the buffer register, there are two types of the transfer timing such as from the buffer register to the temporary register and from the temporary register to the general register.

Note that the buffer transfer-enabled period depends on the T3AEN and T4VEN bit settings in the timer interrupt skipping set register (TITCR). Figure 10.72 shows the relationship between the T3AEN and T4VEN bit settings in TITCR and buffer transfer-enabled period.

Note: This function must always be used in combination with interrupt skipping.
When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that buffer transfer is not linked with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If buffer transfer is linked with interrupt skipping while interrupt skipping is disabled, buffer transfer is never performed.



[Legend]
(1) No data is transferred from the buffer register to the temporary register in the buffer transfer-disabled period (bits BTE1 and BTE0 in TBTER are set to 0 and 1, respectively).
(2) Data is transferred from the temporary register to the general register even in the buffer transfer-disabled period.
(3) After buffer transfer is enabled, data is transferred from the buffer register to the temporary register.

Note: * When buffer transfer at the crest is selected.

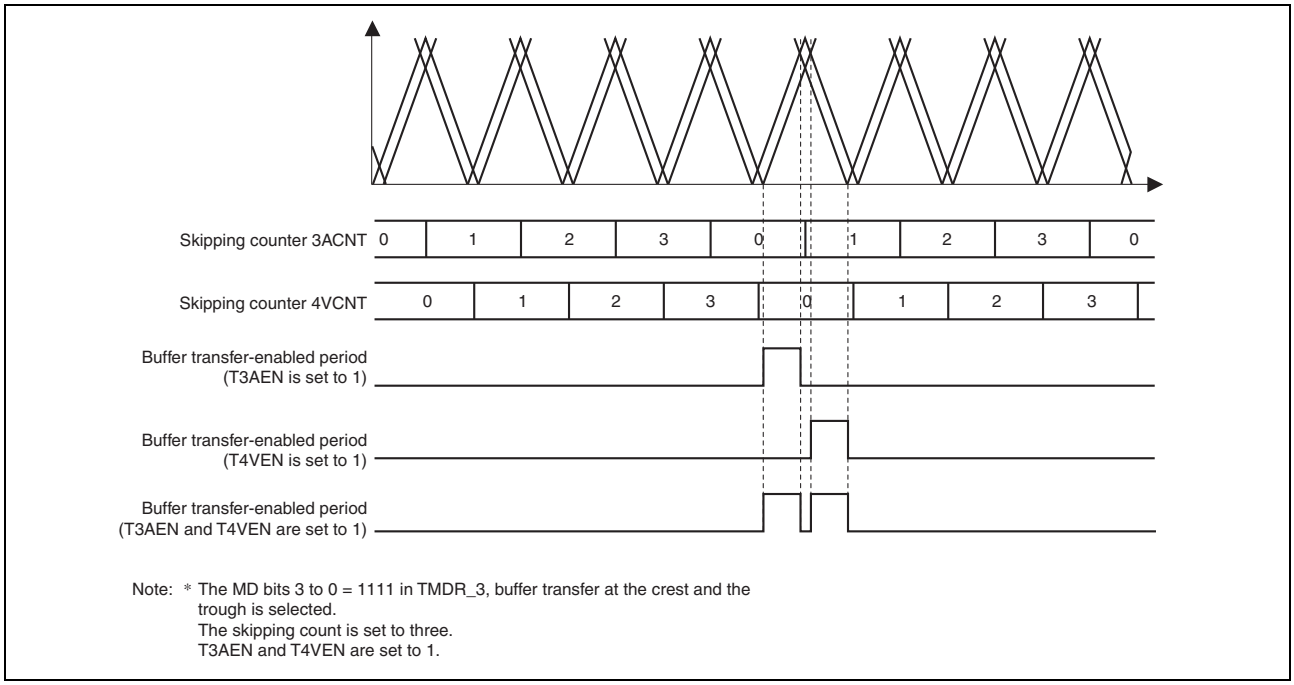

Figure 10.72 Relationship between Bits T3AEN and T4VEN in TITCR and Buffer Transfer-Enabled Period

(4) Complementary PWM Mode Output Protection Function

Complementary PWM mode output has the following protection function.

(a) Register and counter miswrite prevention function

With the exception of the buffer registers, which can be rewritten at any time, access by the CPU can be enabled or disabled for the mode registers, control registers, compare registers, and counters used in complementary PWM mode by means of the RWE bit in the timer read/write enable register (TRWER). The applicable registers are some (21 in total) of the registers in channels 3 and 4 shown in the following:

- TCR_3 and TCR_4, TMDR_3 and TMDR_4, TIORH_3 and TIORH_4, TIORL_3 and TIORL_4, TIER_3 and TIER_4, TCNT_3 and TCNT_4, TGRA_3 and TGRA_4, TGRB_3 and TGRB_4, TOER, TOCR, TGCR, TCDR, and TDDR.

This function enables miswriting due to CPU runaway to be prevented by disabling CPU access to the mode registers, control registers, and counters. When the applicable registers are read in the access-disabled state, undefined values are returned. Writing to these registers is ignored.

10.4.9 A/D Converter Start Request Delaying Function

A/D converter start requests can be issued in channel 4 by making settings in the timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCORA_4 and TADCORB_4), and timer A/D converter start request cycle set buffer registers (TADCOBRA_4 and TADCOBRB_4).

The A/D converter start request delaying function compares TCNT_4 with TADCORA_4 or TADCORB_4, and when their values match, the function issues a respective A/D converter start request (TRG4AN or TRG4BN).

A/D converter start requests (TRG4AN and TRG4BN) can be skipped in coordination with interrupt skipping by setting the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in TADCR.

- Example of Procedure for Specifying A/D Converter Start Request Delaying Function
  Figure 10.73 shows an example of procedure for specifying the A/D converter start request delaying function.

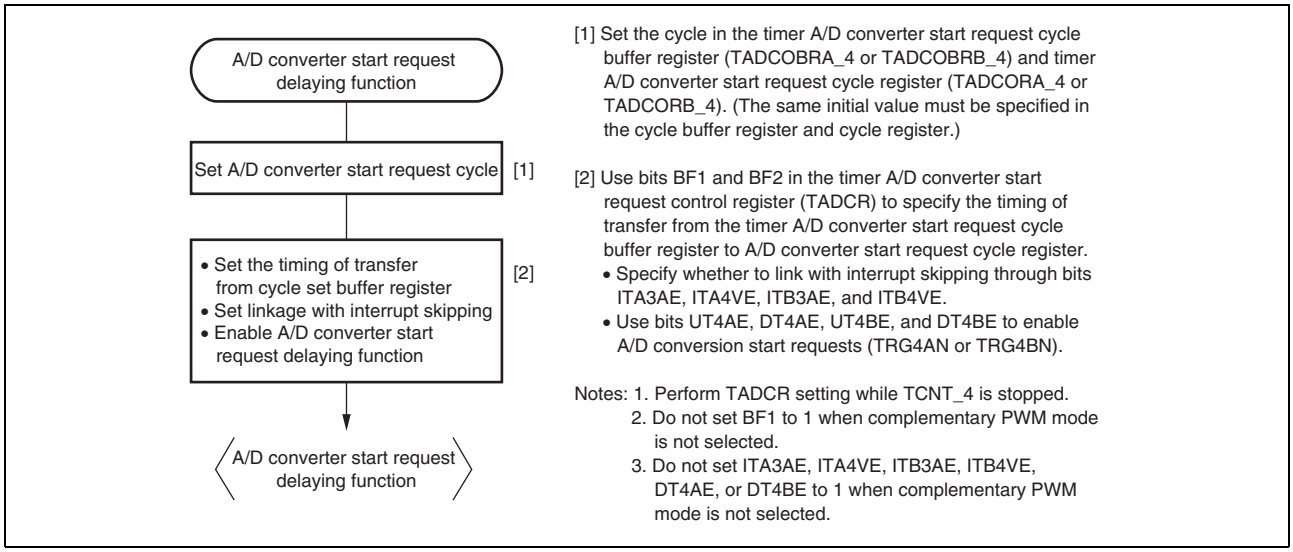

Figure 10.73 Example of Procedure for Specifying A/D Converter Start Request Delaying Function

- Basic Operation Example of A/D Converter Start Request Delaying Function
  Figure 10.74 shows a basic example of A/D converter request signal (TRG4AN) operation when the trough of TCNT_4 is specified for the buffer transfer timing and an A/D converter start request signal is output during TCNT_4 down-counting.

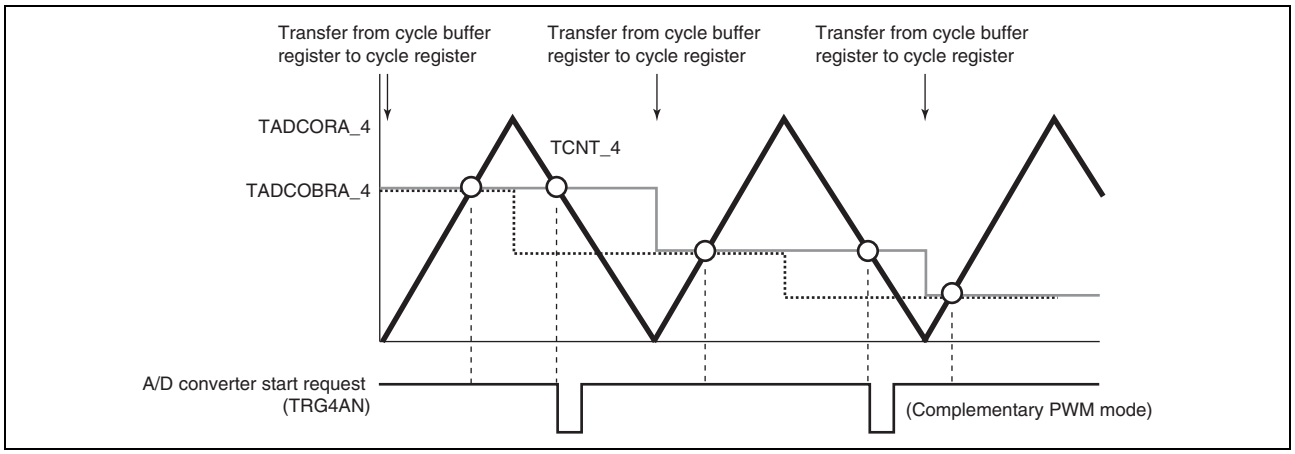

Figure 10.74 Basic Example of A/D Converter Start Request Signal (TRG4AN) Operation

- Buffer Transfer
  The data in the timer A/D converter start request cycle set registers (TADCORA_4 and TADCORB_4) is updated by writing data to the timer A/D converter start request cycle set buffer registers (TADCOBRA_4 and TADCOBRB_4). Data is transferred from the buffer registers to the respective cycle set registers at the timing selected with the BF1 and BF0 bits in the timer A/D converter start request control register (TADCR_4).

- A/D Converter Start Request Delaying Function Linked with Interrupt Skipping
  A/D converter start requests (TRG4AN and TRG4BN) can be issued in coordination with interrupt skipping by making settings in the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR).
  Figure 10.75 shows an example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT_4 up counting and down counting and A/D converter start requests are linked with interrupt skipping.
  Figure 10.76 shows another example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT_4 up counting and A/D converter start requests are linked with interrupt skipping.

Note: This function must be used in combination with interrupt skipping.
When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that A/D converter start requests are not linked with interrupt skipping (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).

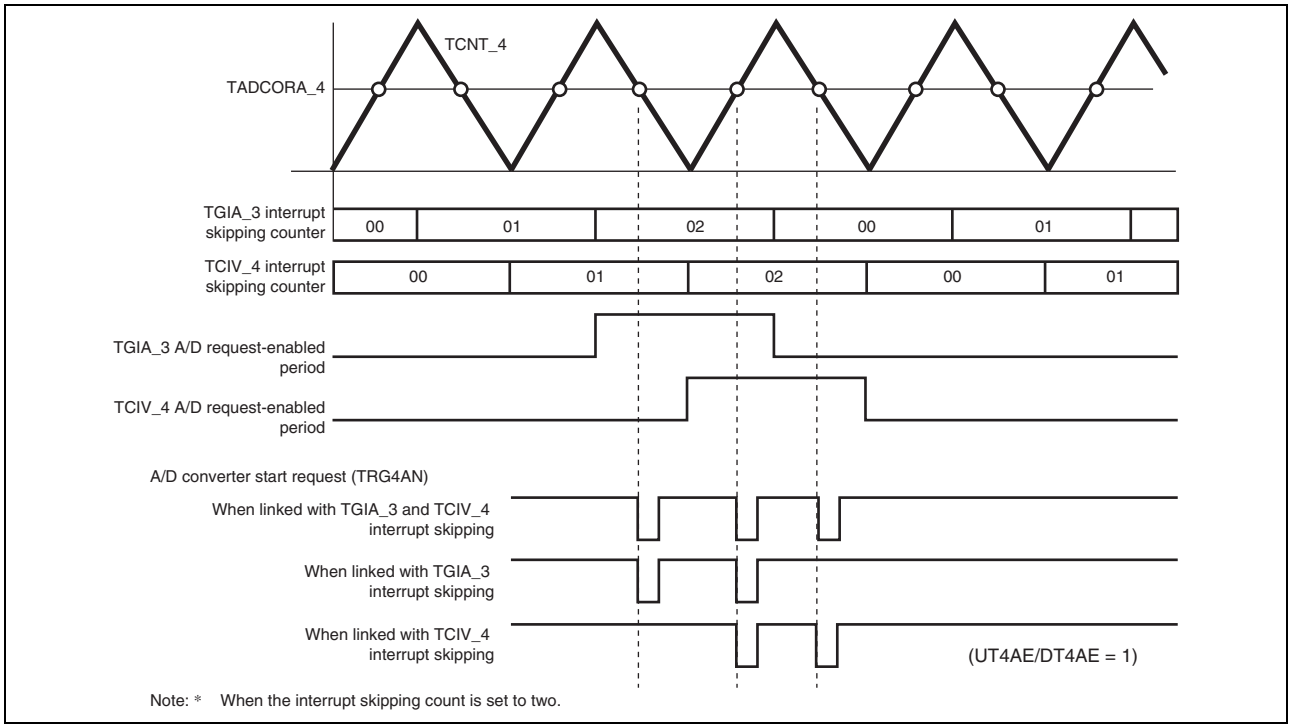

Figure 10.75 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping

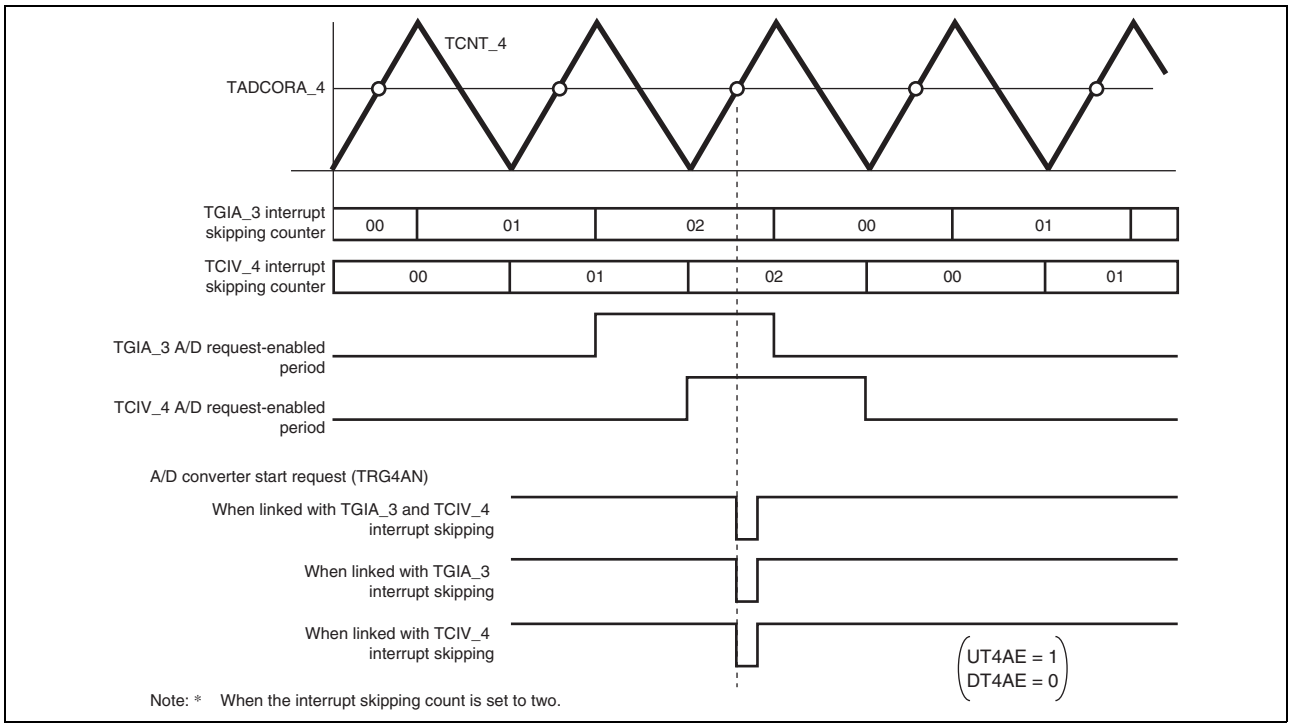

Figure 10.76 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping

10.4.10 TCNT Capture at Crest and/or Trough in Complementary PWM Operation

The TCNT value is captured in TGR at either the crest or trough or at both the crest and trough during complementary PWM operation. The timing for capturing in TGR can be selected by TIOR.

Figure 10.77 shows an example in which TCNT is used as a free-running counter without being cleared, and the TCNT value is captured in TGR at the specified timing (either crest or trough, or both crest and trough).

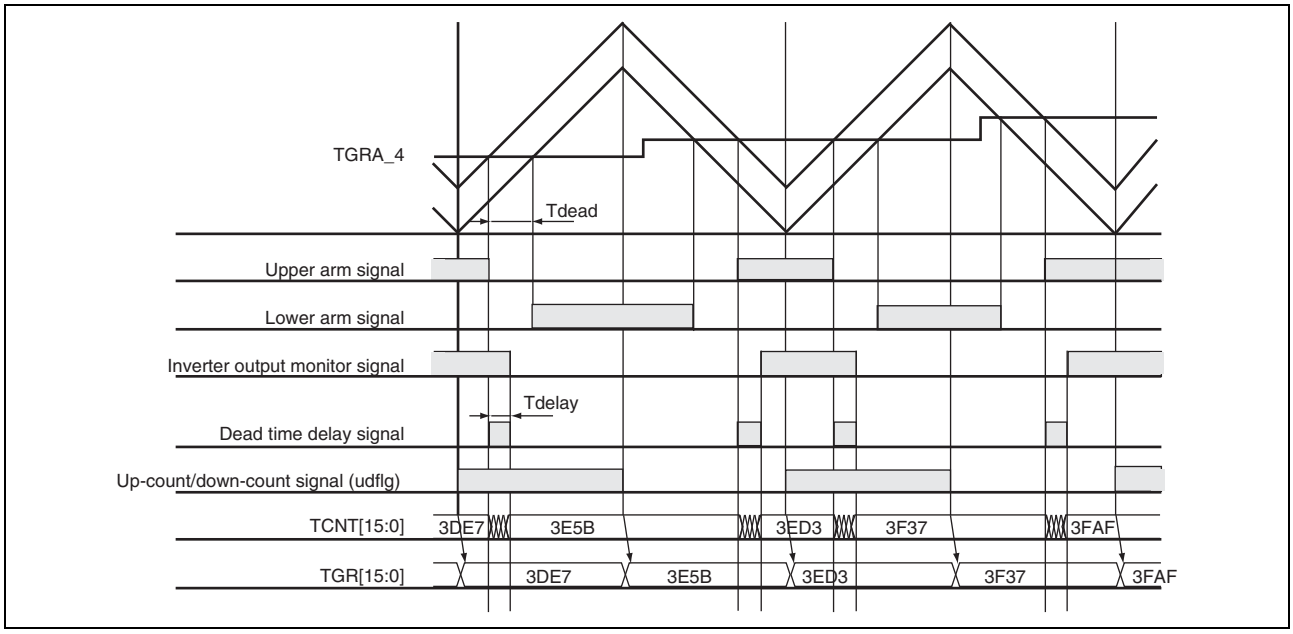

Figure 10.77 TCNT Capturing at Crest and/or Trough in Complementary PWM Operation

10.5 Interrupt Sources

10.5.1 Interrupt Sources and Priorities

This module has three kinds of interrupt sources; TGR input capture/compare match, TCNT overflow, and TCNT underflow. Each interrupt source has its own status flag and enable/disabled bit, allowing the generation of interrupt request signals to be enabled or disabled individually.

When an interrupt request is generated, the corresponding status flag in TSR is set to 1. If the corresponding enable/disable bit in TIER is set to 1 at this time, an interrupt is requested. The interrupt request is cleared by clearing the status flag to 0.

Relative channel priorities can be changed by the interrupt controller, however the priority order within a channel is fixed. For details, see section 7, Interrupt Controller.

Table 10.55 lists the interrupt sources of this module.

Table 10.55 Interrupts of Multi-Function Timer Pulse Unit 2

Channel	Name	Interrupt Source	Interrupt Flag	Activation of Direct Memory Access Controller	Priority
0	TGIA_0	TGRA_0 input capture/compare match	TGFA_0	Possible	High
	TGIB_0	TGRB_0 input capture/compare match	TGFB_0	Not possible	
	TGIC_0	TGRC_0 input capture/compare match	TGFC_0	Not possible	
	TGID_0	TGRD_0 input capture/compare match	TGFD_0	Not possible	
	TCIV_0	TCNT_0 overflow	TCFV_0	Not possible	
	TGIE_0	TGRE_0 compare match	TGFE_0	Not possible	
	TGIF_0	TGRF_0 compare match	TGFF_0	Not possible	
1	TGIA_1	TGRA_1 input capture/compare match	TGFA_1	Possible	
	TGIB_1	TGRB_1 input capture/compare match	TGFB_1	Not possible	
	TCIV_1	TCNT_1 overflow	TCFV_1	Not possible	
	TCIU_1	TCNT_1 underflow	TCFU_1	Not possible	
2	TGIA_2	TGRA_2 input capture/compare match	TGFA_2	Possible	
	TGIB_2	TGRB_2 input capture/compare match	TGFB_2	Not possible	
	TCIV_2	TCNT_2 overflow	TCFV_2	Not possible	
	TCIU_2	TCNT_2 underflow	TCFU_2	Not possible	
3	TGIA_3	TGRA_3 input capture/compare match	TGFA_3	Possible	
	TGIB_3	TGRB_3 input capture/compare match	TGFB_3	Not possible	
	TGIC_3	TGRC_3 input capture/compare match	TGFC_3	Not possible	
	TGID_3	TGRD_3 input capture/compare match	TGFD_3	Not possible	
	TCIV_3	TCNT_3 overflow	TCFV_3	Not possible	
4	TGIA_4	TGRA_4 input capture/compare match	TGFA_4	Possible	
	TGIB_4	TGRB_4 input capture/compare match	TGFB_4	Not possible	
	TGIC_4	TGRC_4 input capture/compare match	TGFC_4	Not possible	
	TGID_4	TGRD_4 input capture/compare match	TGFD_4	Not possible	
	TCIV_4	TCNT_4 overflow/underflow	TCFV_4	Not possible	Low

Note: This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

(1) Input Capture/Compare Match Interrupt

An interrupt is requested if the TGIE bit in TIER is set to 1 when the TGF flag in TSR is set to 1 by the occurrence of a TGR input capture/compare match on a particular channel. The interrupt request is cleared by clearing the TGF flag to 0. This module has eighteen input capture/compare match interrupts, six for channel 0, four each for channels 3 and 4, and two each for channels 1 and 2. The TGFE_0 and TGFF_0 flags in channel 0 are not set by the occurrence of an input capture.

(2) Overflow Interrupt

An interrupt is requested if the TCIEV bit in TIER is set to 1 when the TCFV flag in TSR is set to 1 by the occurrence of TCNT overflow on a channel. The interrupt request is cleared by clearing the TCFV flag to 0. This module has five overflow interrupts, one for each channel.

(3) Underflow Interrupt

An interrupt is requested if the TCIEU bit in TIER is set to 1 when the TCFU flag in TSR is set to 1 by the occurrence of TCNT underflow on a channel. The interrupt request is cleared by clearing the TCFU flag to 0. This module has two underflow interrupts, one each for channels 1 and 2.

10.5.2 Activation of Direct Memory Access Controller

The direct memory access controller can be activated by the TGRA input capture/compare match interrupt in each channel. For details, see section 9, Direct Memory Access Controller.

In this module, a total of five TGRA input capture/compare match interrupts can be used as direct memory access controller activation sources, one each for channels 0 to 4.

10.5.3 A/D Converter Activation

The A/D converter can be activated by one of the following three methods in this module. Table 10.56 shows the relationship between interrupt sources and A/D converter start request signals.

(1) A/D Converter Activation by TGRA Input Capture/Compare Match or at TCNT_4 Trough in Complementary PWM Mode

The A/D converter can be activated by the occurrence of a TGRA input capture/compare match in each channel. In addition, if complementary PWM operation is performed while the TTGE2 bit in TIER_4 is set to 1, the A/D converter can be activated at the trough of TCNT_4 count (TCNT_4 = H'0000).

A/D converter start request signal TRGAN is issued to the A/D converter under either one of the following conditions.

- When the TGFA flag in TSR is set to 1 by the occurrence of a TGRA input capture/compare match on a particular channel while the TTGE bit in TIER is set to 1
- When the TCNT_4 count reaches the trough (TCNT_4 = H'0000) during complementary PWM operation while the TTGE2 bit in TIER_4 is set to 1

When either condition is satisfied, if A/D converter start signal TRGAN from this module is selected as the trigger in the A/D converter, A/D conversion will start.

(2) A/D Converter Activation by Compare Match between TCNT_0 and TGRE_0

The A/D converter can be activated by generating A/D converter start request signal TRG0N when a compare match occurs between TCNT_0 and TGRE_0 in channel 0.

When the TGFE flag in TSR2_0 is set to 1 by the occurrence of a compare match between TCNT_0 and TGRE_0 in channel 0 while the TTGE2 bit in TIER2_0 is set to 1, A/D converter start request TGR0N is issued to the A/D converter. If A/D converter start signal TGR0N from this module is selected as the trigger in the A/D converter, A/D conversion will start.

(3) A/D Converter Activation by A/D Converter Start Request Delaying Function

The A/D converter can be activated by generating A/D converter start request signal TRG4AN or TRG4BN when the TCNT_4 count matches the TADCORA or TADCORB value if the UT4AE, DT4AE, UT4BE, or DT4BE bit in the A/D converter start request control register (TADCR) is set to 1. For details, refer to section 10.4.9, A/D Converter Start Request Delaying Function.

A/D conversion will start if A/D converter start signal TRG4AN from this module is selected as the trigger in the A/D converter when TRG4AN is generated or if TRG4BN from this module is selected as the trigger in the A/D converter when TRG4BN is generated.

Table 10.56 Interrupt Sources and A/D Converter Start Request Signals

Target Registers	Interrupt Source	A/D Converter Start Request Signal
TGRA_0 and TCNT_0	Input capture/compare match	TRGAN
TGRA_1 and TCNT_1		
TGRA_2 and TCNT_2		
TGRA_3 and TCNT_3		
TGRA_4 and TCNT_4		
TCNT_4	TCNT_4 Trough in complementary PWM mode	
TGRE_0 and TCNT_0	Compare match	TRG0N
TADCORA and TCNT_4		TRG4AN
TADCORB and TCNT_4		TRG4BN

10.6 Operation Timing

10.6.1 Input/Output Timing

(1) TCNT Count Timing

Figure 10.78 shows TCNT count timing in internal clock operation, and Figure 10.79 shows TCNT count timing in external clock operation (normal mode), and Figure 10.80 shows TCNT count timing in external clock operation (phase counting mode).

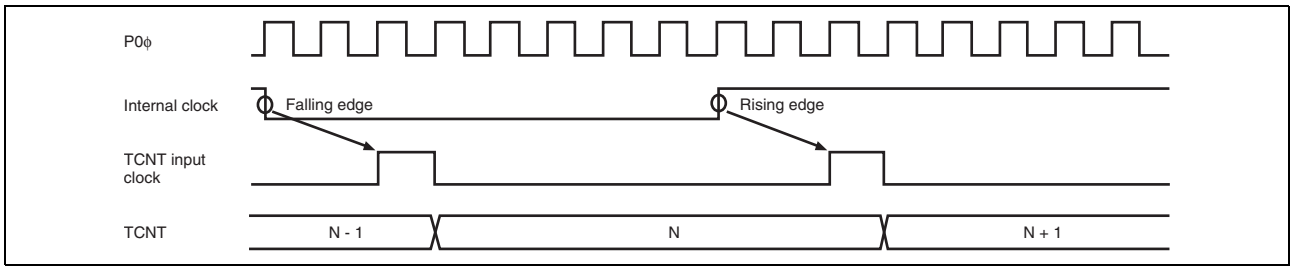

Figure 10.78 Count Timing in Internal Clock Operation

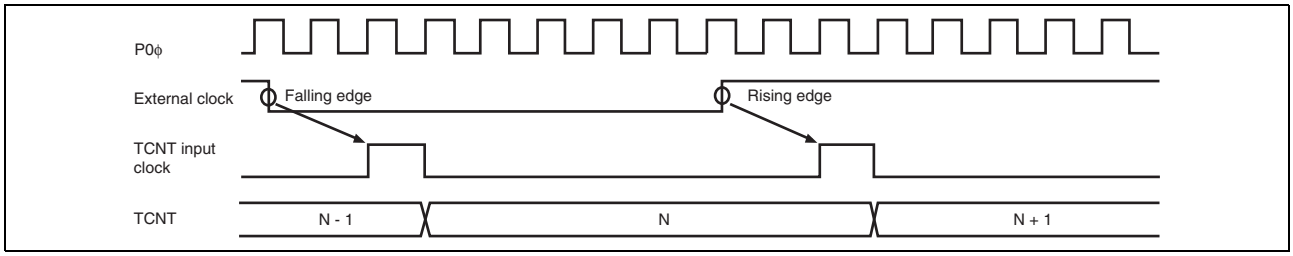

Figure 10.79 Count Timing in External Clock Operation

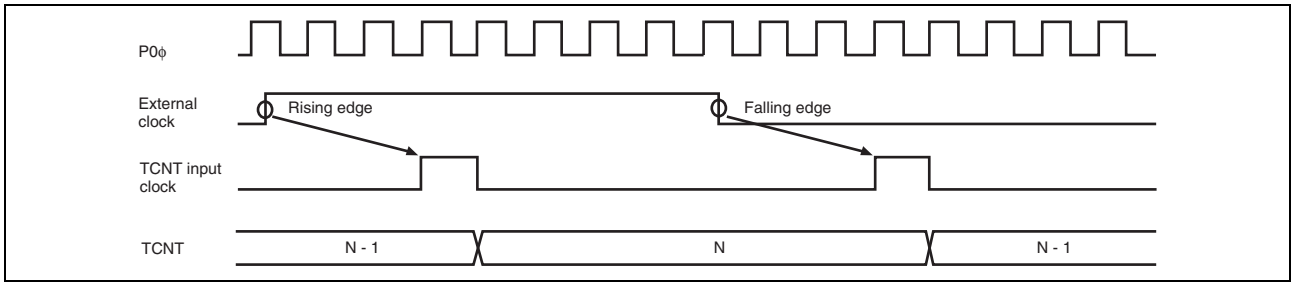

Figure 10.80 Count Timing in External Clock Operation (Phase Counting Mode)

(2) Output Compare Output Timing

A compare match signal is generated in the final state in which TCNT and TGR match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TIOR is output at the output compare output pin (TIOC pin). After a match between TCNT and TGR, the compare match signal is not generated until the TCNT input clock is generated.

Figure 10.81 shows output compare output timing (normal mode and PWM mode) and Figure 10.82 shows output compare output timing (complementary PWM mode and reset synchronous PWM mode).

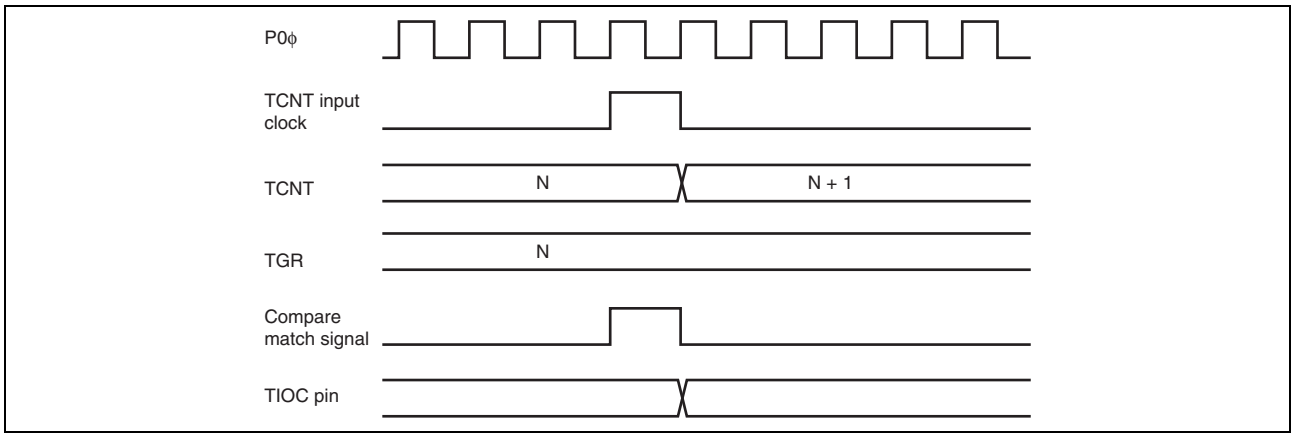

Figure 10.81 Output Compare Output Timing (Normal Mode/PWM Mode)

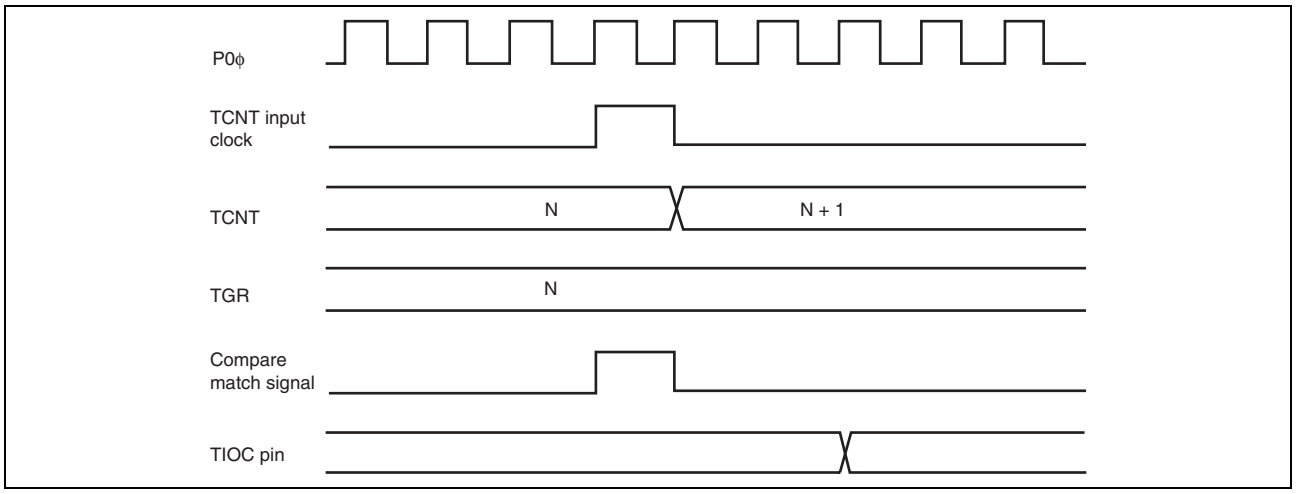

Figure 10.82 Output Compare Output Timing (Complementary PWM Mode/Reset Synchronous PWM Mode)

(3) Input Capture Signal Timing

Figure 10.83 shows input capture signal timing.

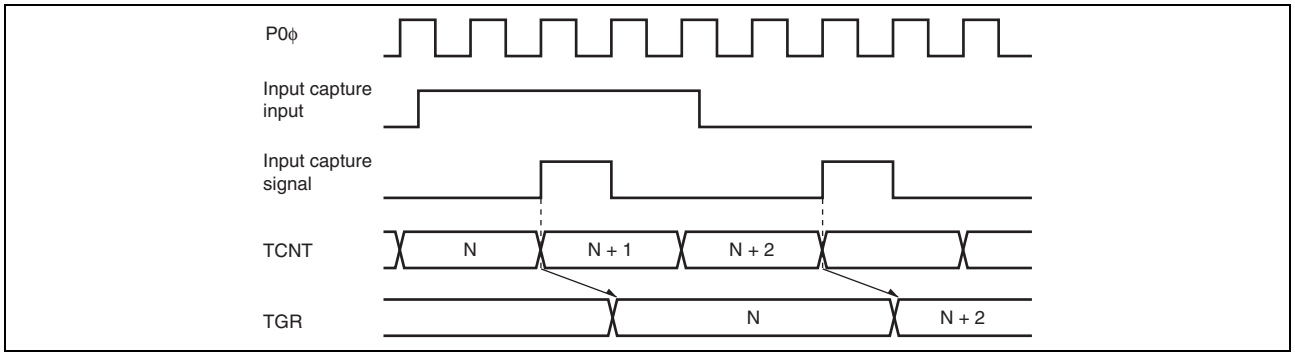

Figure 10.83 Input Capture Input Signal Timing

(4) Timing for Counter Clearing by Compare Match/Input Capture

Figure 10.84 shows the timing when counter clearing on compare match is specified, and Figure 10.85 shows the timing when counter clearing on input capture is specified.

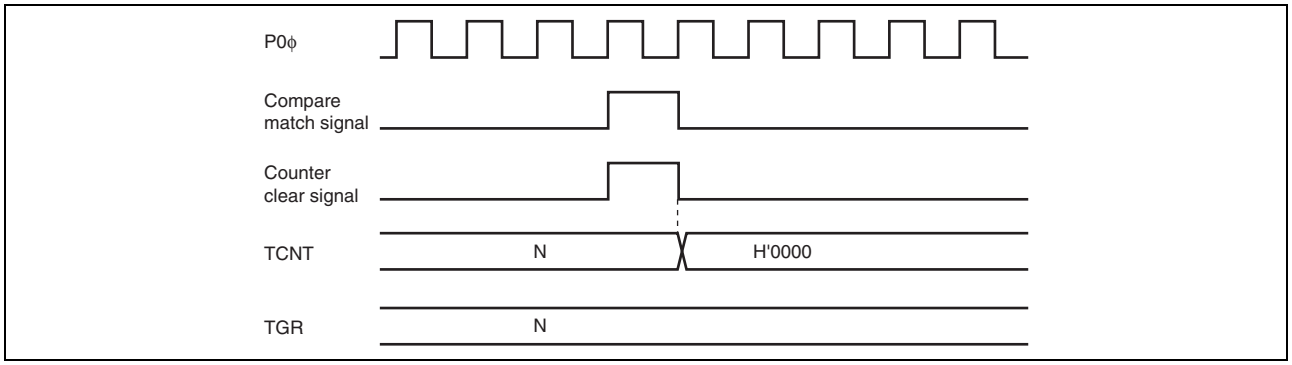

Figure 10.84 Counter Clear Timing (Compare Match)

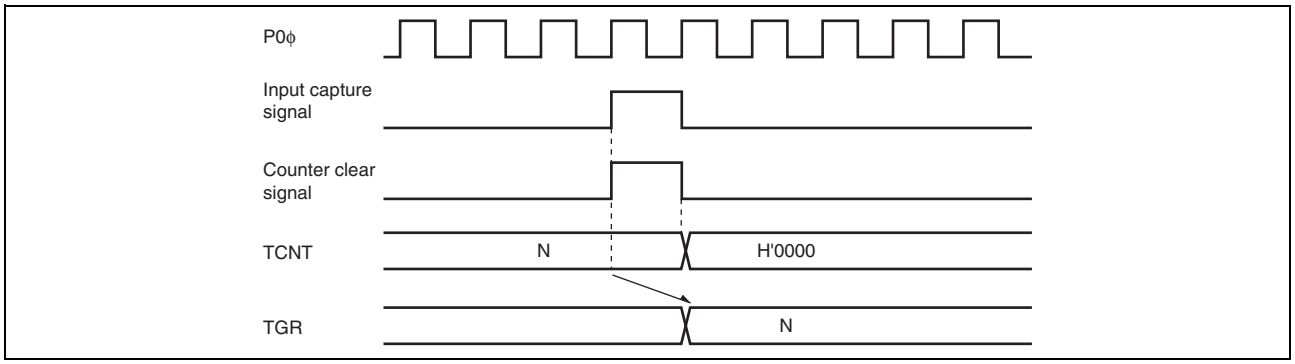

Figure 10.85 Counter Clear Timing (Input Capture)

(5) Buffer Operation Timing

Figure 10.86 to Figure 10.88 show the timing in buffer operation.

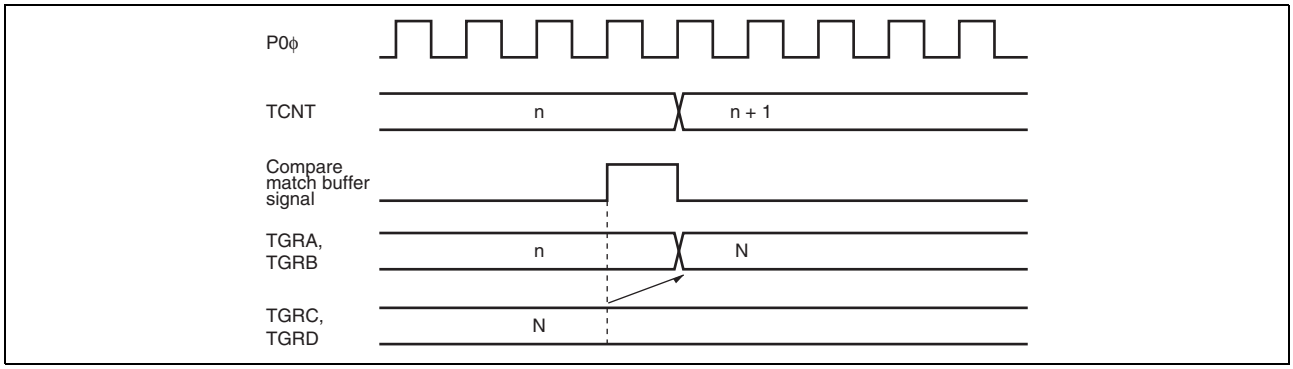

Figure 10.86 Buffer Operation Timing (Compare Match)

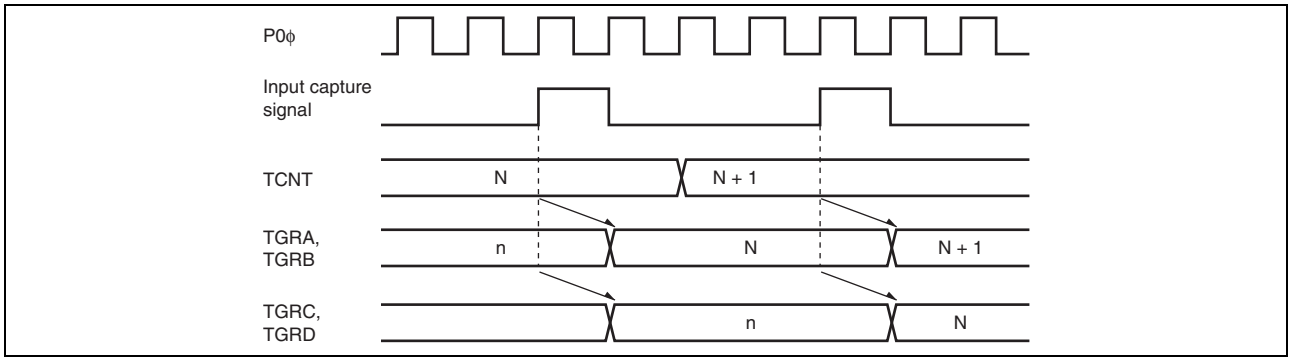

Figure 10.87 Buffer Operation Timing (Input Capture)

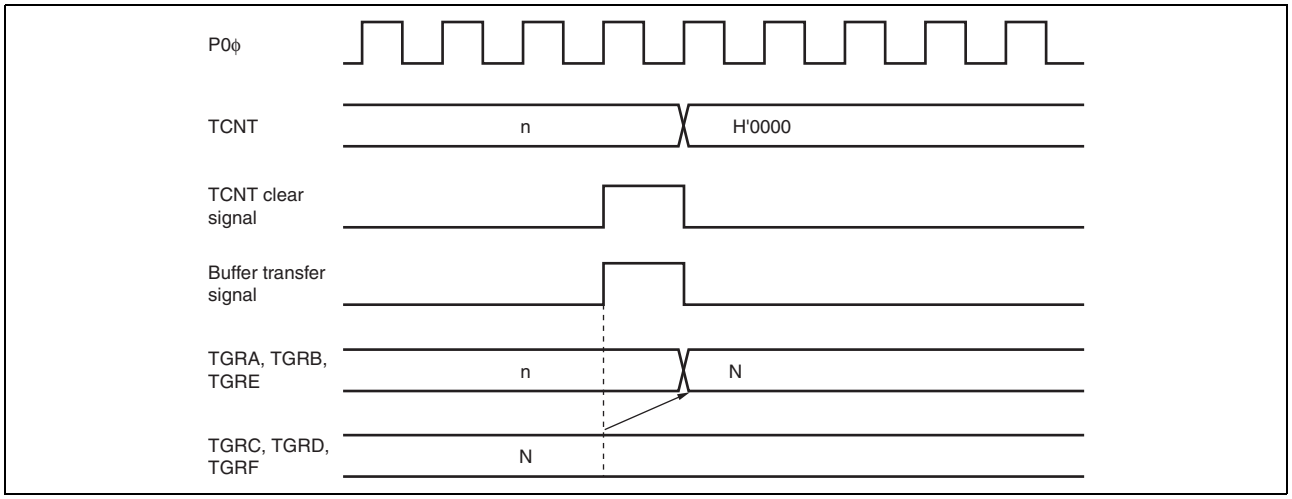

Figure 10.88 Buffer Transfer Timing (when TCNT Cleared)

(6) Buffer Transfer Timing (Complementary PWM Mode)

Figure 10.89 to Figure 10.91 show the buffer transfer timing in complementary PWM mode.

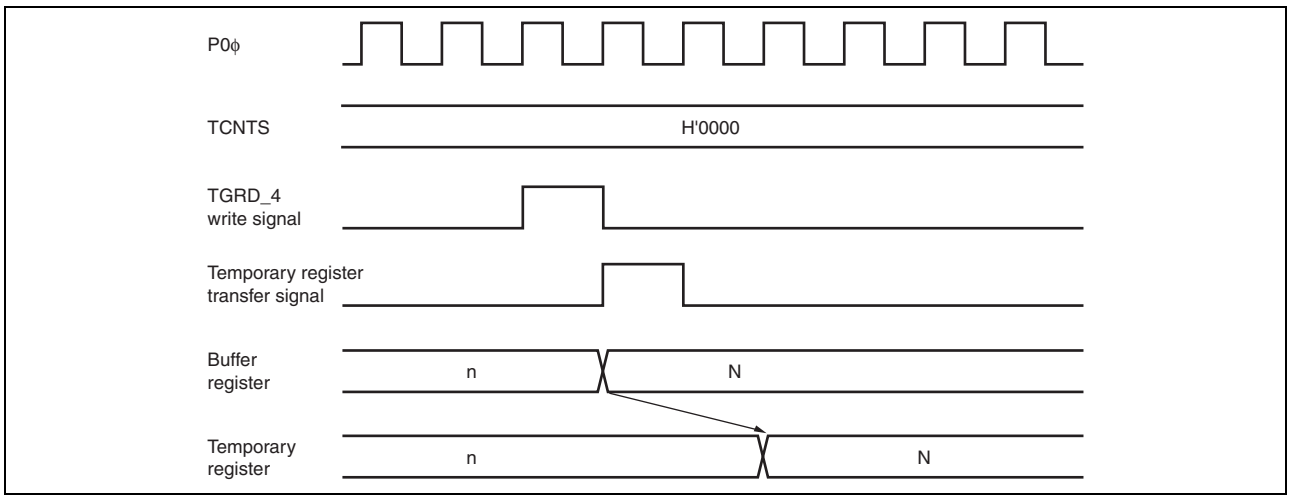

Figure 10.89 Transfer Timing from Buffer Register to Temporary Register (TCNTS Stop)

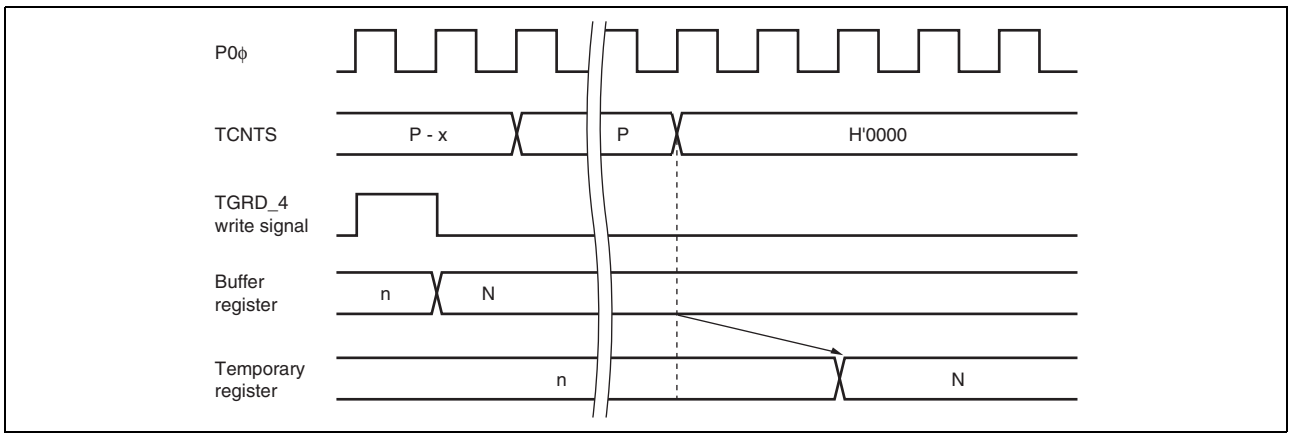

Figure 10.90 Transfer Timing from Buffer Register to Temporary Register (TCNTS Operating)

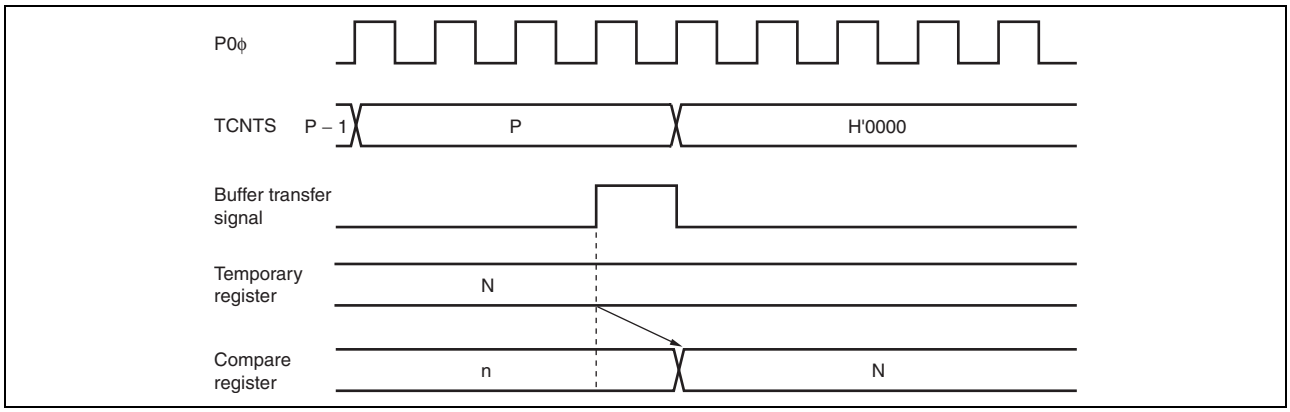

Figure 10.91 Transfer Timing from Temporary Register to Compare Register

10.6.2 Interrupt Signal Timing

(1) TGF Flag Setting Timing in Case of Compare Match

Figure 10.92 shows the timing for setting of the TGF flag in TSR on compare match, and TGI interrupt request signal timing.

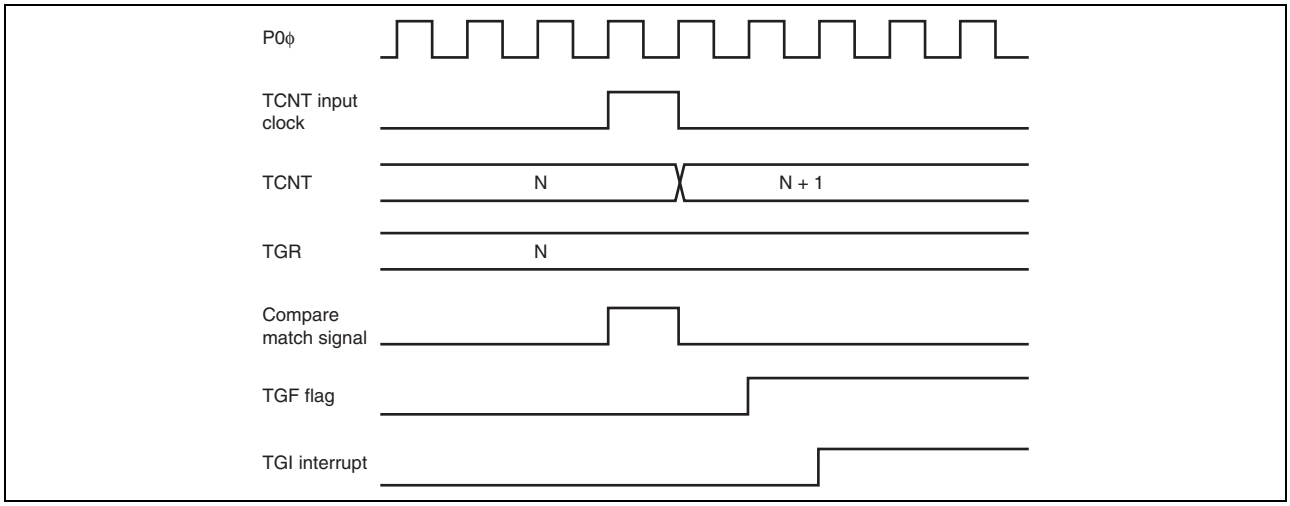

Figure 10.92 TGI Interrupt Timing (Compare Match)

(2) TGF Flag Setting Timing in Case of Input Capture

Figure 10.93 shows the timing for setting of the TGF flag in TSR on input capture, and TGI interrupt request signal timing.

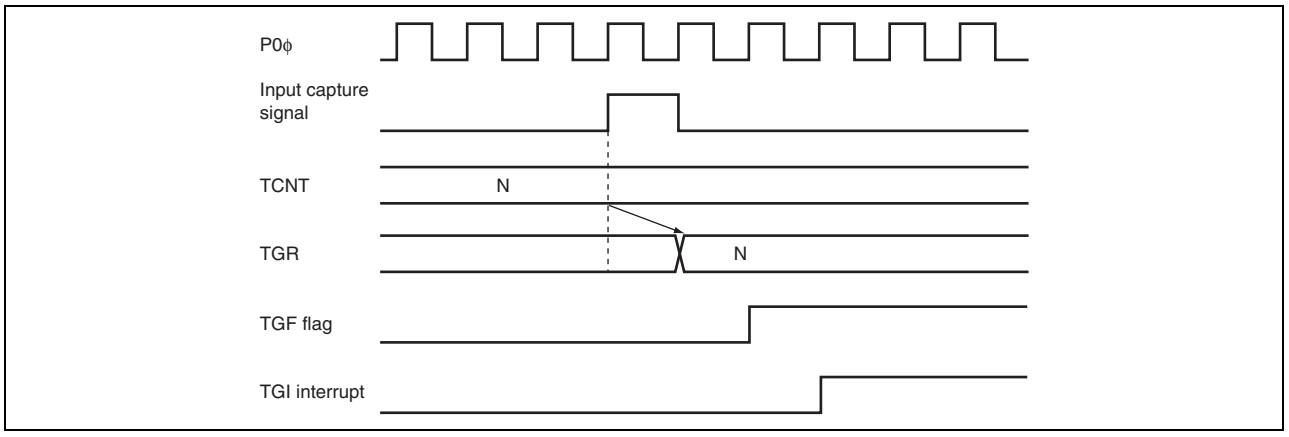

Figure 10.93 TGI Interrupt Timing (Input Capture)

(3) TCFV Flag/TCFU Flag Setting Timing

Figure 10.94 shows the timing for setting of the TCFV flag in TSR on overflow, and TCIV interrupt request signal timing.

Figure 10.95 shows the timing for setting of the TCFU flag in TSR on underflow, and TCIU interrupt request signal timing.

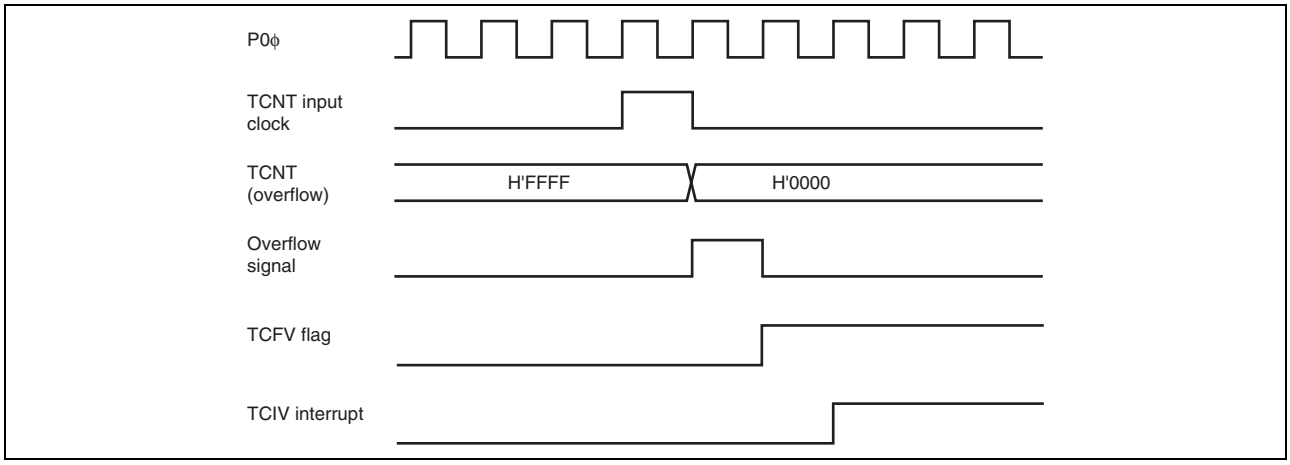

Figure 10.94 TCIV Interrupt Setting Timing

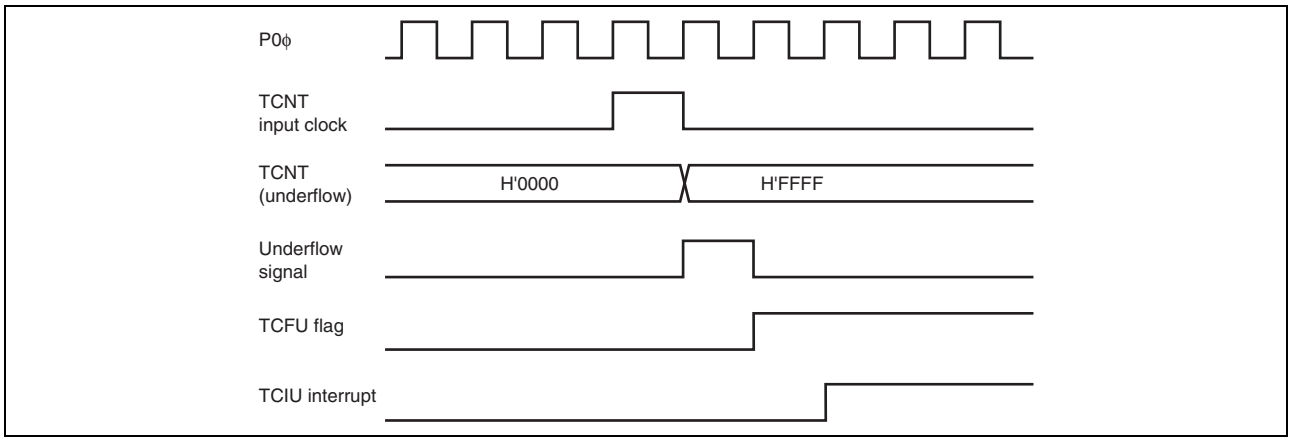

Figure 10.95 TCIU Interrupt Setting Timing

(4) Status Flag Clearing Timing

After a status flag is read as 1 by the CPU, it is cleared by writing 0 to it. When the direct memory access controller is activated, the flag is cleared automatically. Figure 10.96 shows the timing for status flag clearing by the CPU, and Figure 10.97 shows the timing for status flag clearing by the direct memory access controller.

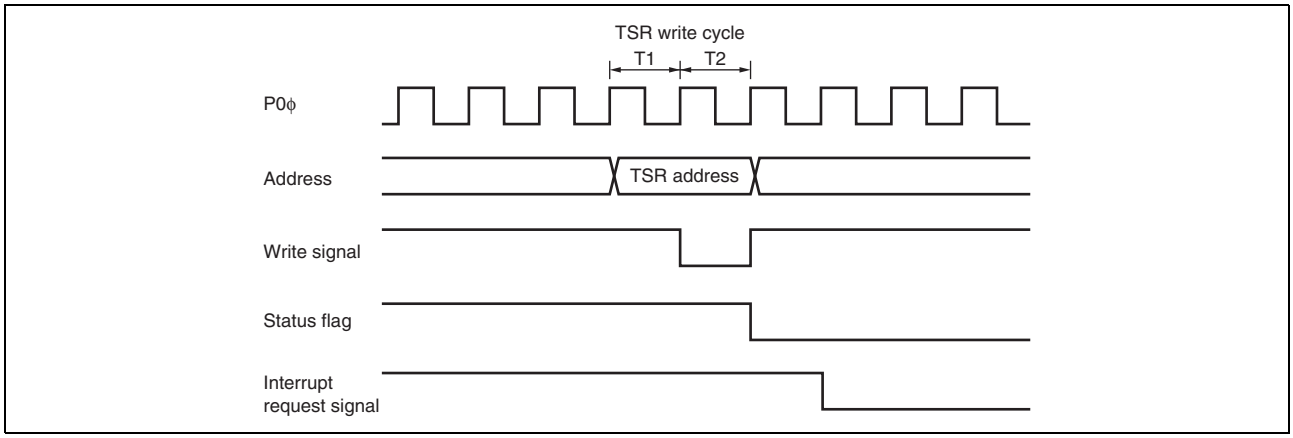

Figure 10.96 Timing for Status Flag Clearing by CPU

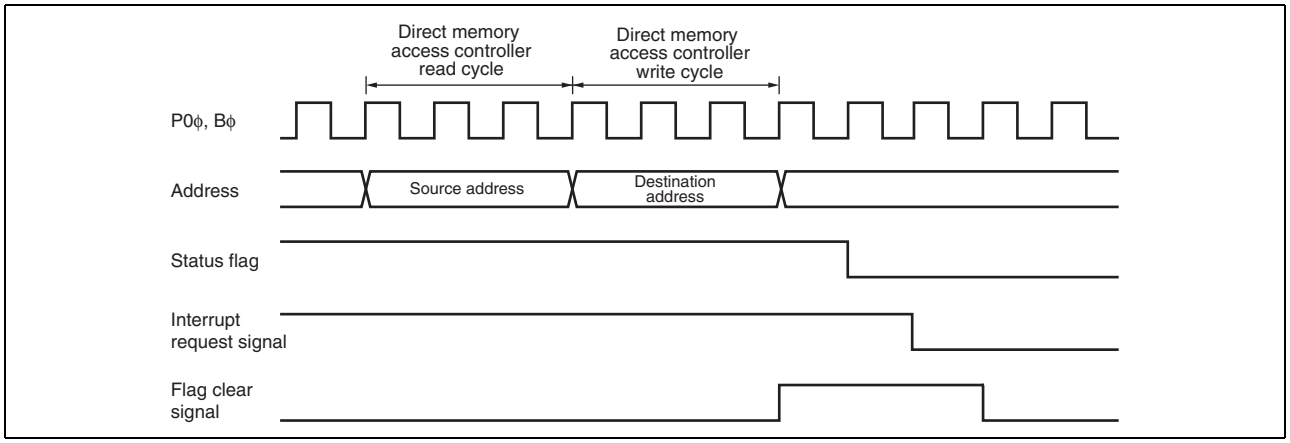

Figure 10.97 Timing for Status Flag Clearing by Direct Memory Access Controller Activation

10.7 Usage Notes

10.7.1 Module Standby Mode Setting

Operation of this module can be disabled or enabled using the standby control register. The initial setting is for the operation to be halted. Register access is enabled by clearing module standby mode. For details, refer to section 42, Power-Down Modes.

10.7.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 states in the case of single-edge detection, and at least 2.5 states in the case of both-edge detection. This module will not operate properly at narrower pulse widths.

In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 states, and the pulse width must be at least 2.5 states. Figure 10.98 shows the input clock conditions in phase counting mode.

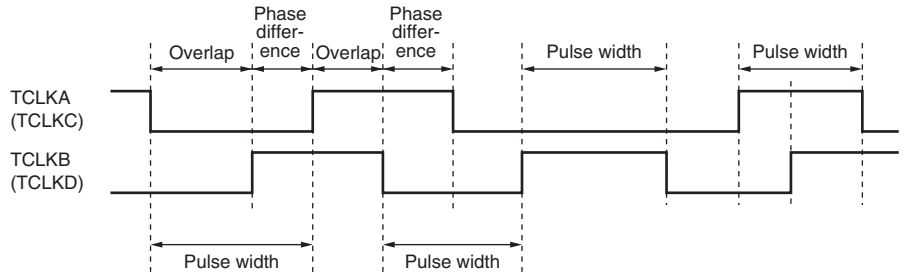

Figure 10.98 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode

10.7.3 Caution on Period Setting

When counter clearing on compare match is set, TCNT is cleared in the final state in which it matches the TGR value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

$$f = \frac{P0\phi}{(N+1)}$$

Where f: Counter frequency
P0ϕ: Peripheral clock operating frequency
N: TGR set value

10.7.4 Contention between TCNT Write and Clear Operations

If the counter clear signal is generated in the T2 state of a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed.

Figure 10.99 shows the timing in this case.

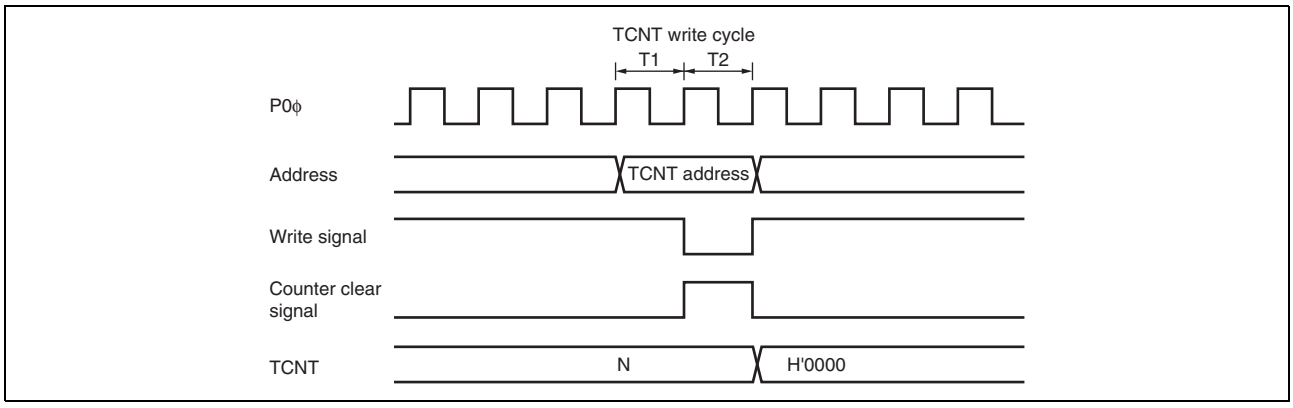

Figure 10.99 Contention between TCNT Write and Clear Operations

10.7.5 Contention between TCNT Write and Increment Operations

If incrementing occurs in the T2 state of a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented.

Figure 10.100 shows the timing in this case.

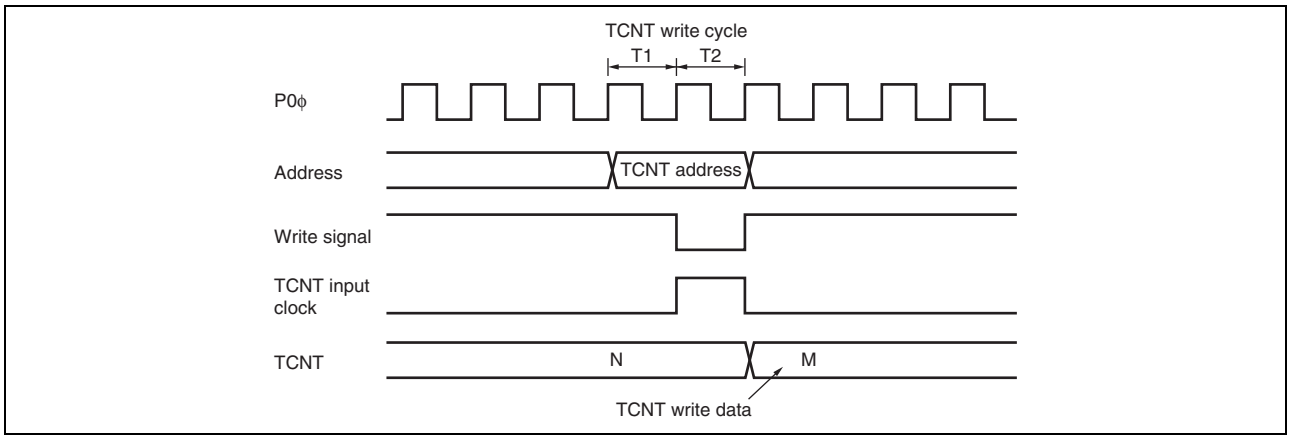

Figure 10.100 Contention between TCNT Write and Increment Operations

10.7.6 Contention between TGR Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the TGR write is executed and the compare match signal is also generated.

Figure 10.101 shows the timing in this case.

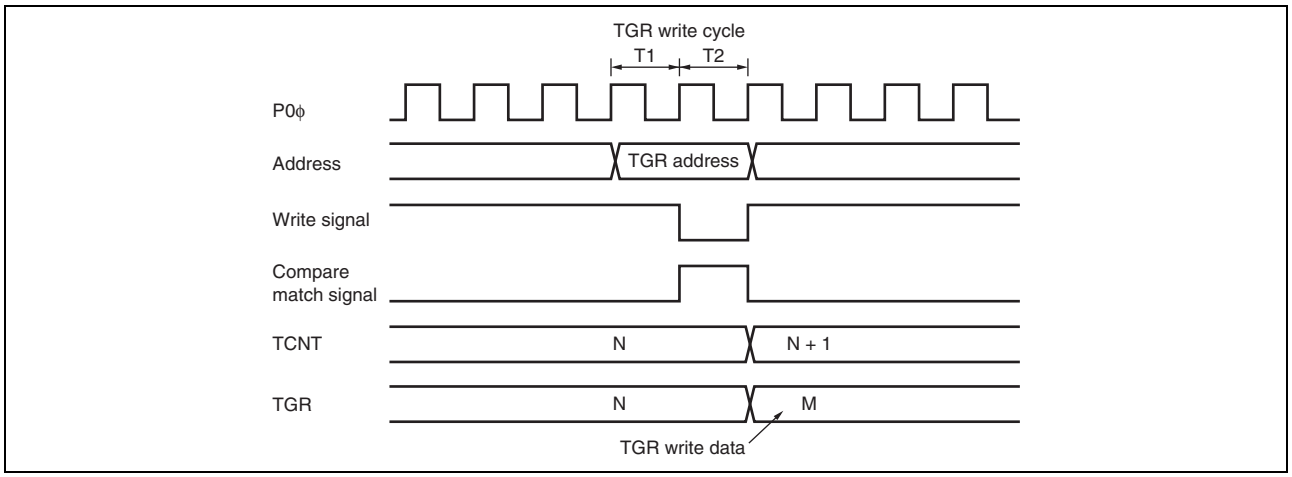

Figure 10.101 Contention between TGR Write and Compare Match

10.7.7 Contention between Buffer Register Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data after write.

Figure 10.102 shows the timing in this case.

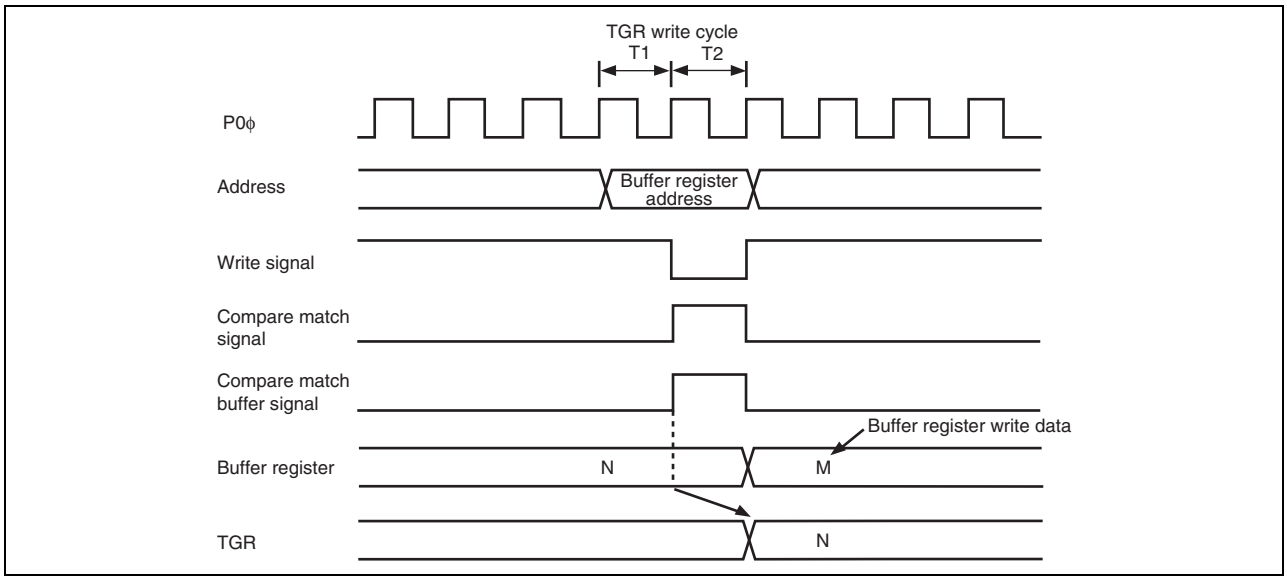

Figure 10.102 Contention between Buffer Register Write and Compare Match

10.7.8 Contention between Buffer Register Write and TCNT Clear

When the buffer transfer timing is set at the TCNT clear by the buffer transfer mode register (TBTM), if TCNT clear occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data before write.

Figure 10.103 shows the timing in this case.

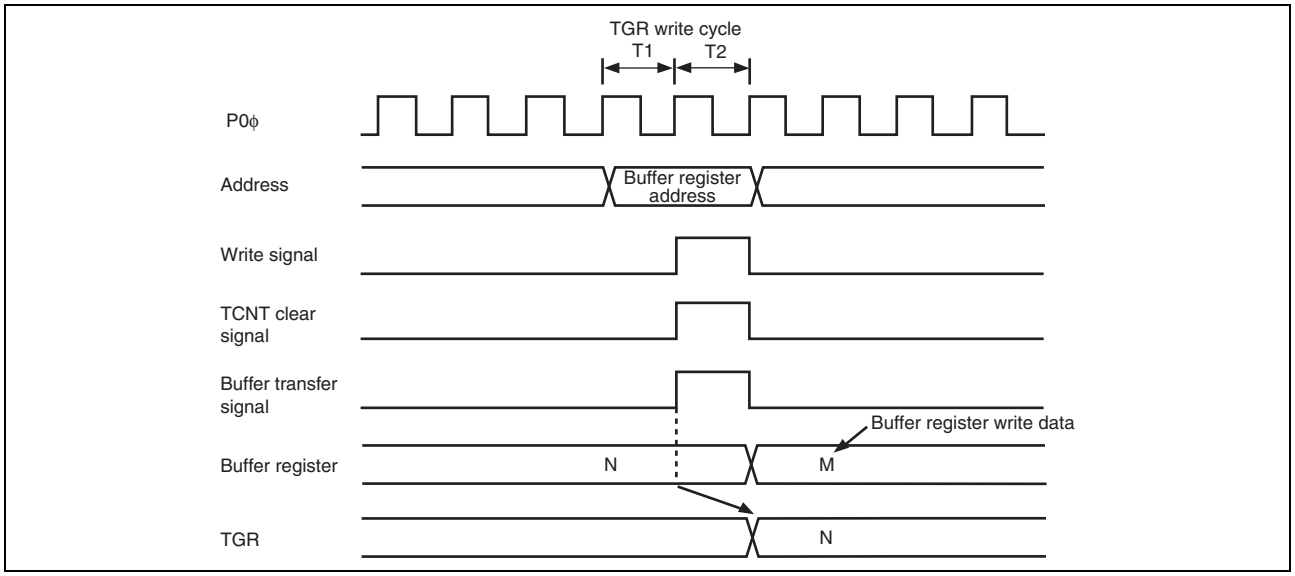

Figure 10.103 Contention between Buffer Register Write and TCNT Clear

10.7.9 Contention between TGR Read and Input Capture

If an input capture signal is generated in the T1 state of a TGR read cycle, the data that is read will be the data in the buffer before input capture transfer.

Figure 10.104 shows the timing in this case.

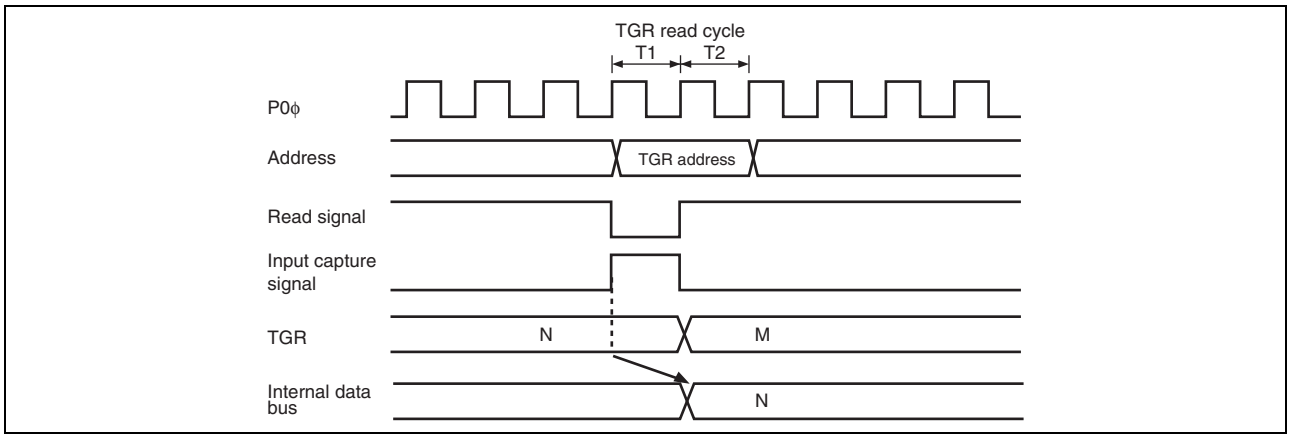

Figure 10.104 Contention between TGR Read and Input Capture

10.7.10 Contention between TGR Write and Input Capture

If an input capture signal is generated in the T2 state of a TGR write cycle, the input capture operation takes precedence and the write to TGR is not performed.

Figure 10.105 shows the timing in this case.

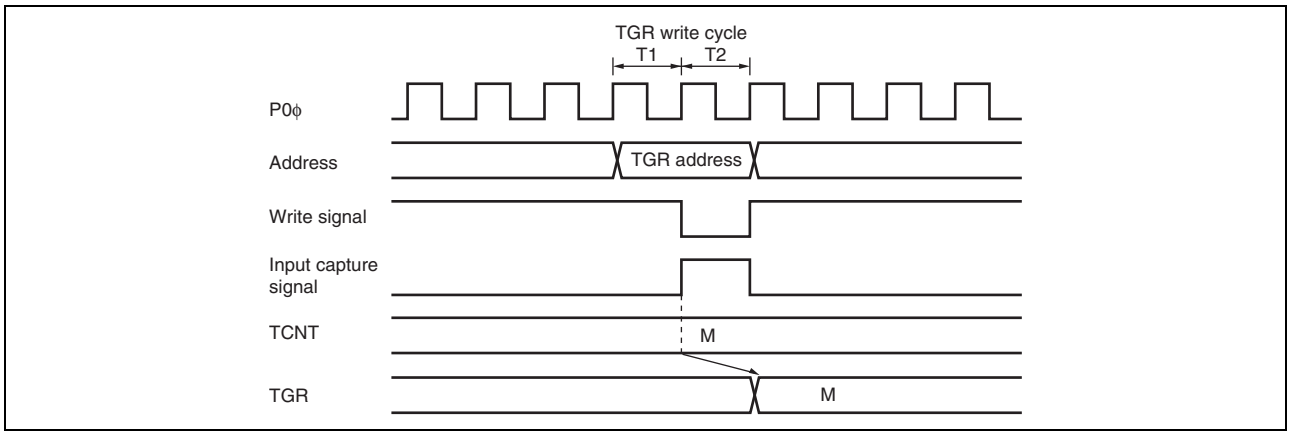

Figure 10.105 Contention between TGR Write and Input Capture

10.7.11 Contention between Buffer Register Write and Input Capture

If an input capture signal is generated in the T2 state of a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed.

Figure 10.106 shows the timing in this case.

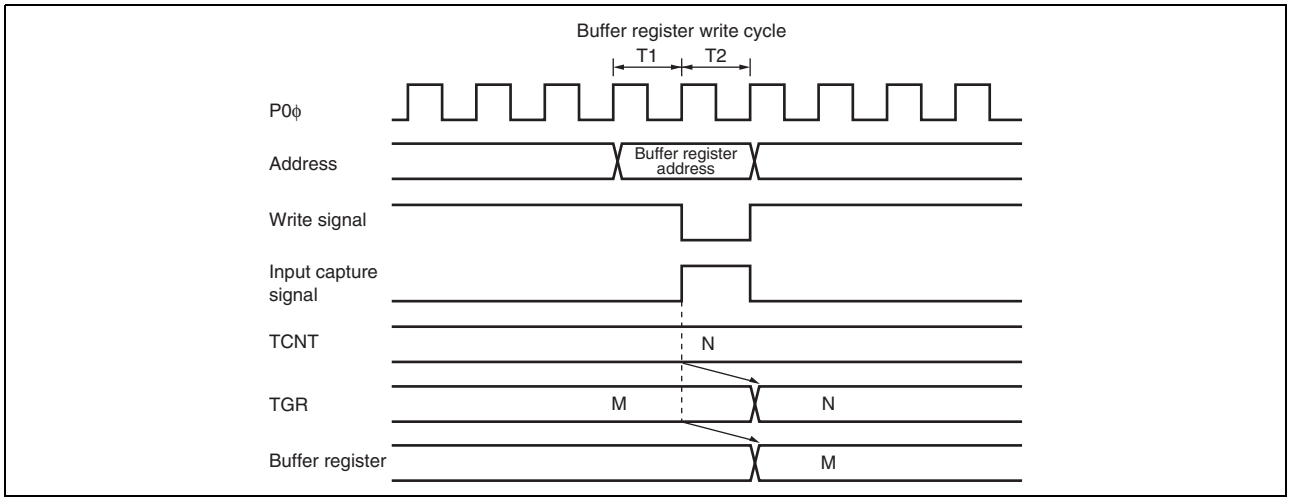

Figure 10.106 Contention between Buffer Register Write and Input Capture

10.7.12 TCNT_2 Write and Overflow/Underflow Contention in Cascade Connection

With timer counters TCNT_1 and TCNT_2 in a cascade connection, when a contention occurs during TCNT_1 count (during a TCNT_2 overflow/underflow) in the T_2 state of the TCNT_2 write cycle, the write to TCNT_2 is conducted, and the TCNT_1 count signal is disabled. At this point, if there is match with TGRA_1 and the TCNT_1 value, a compare signal is issued. Furthermore, when the TCNT_1 count clock is selected as the input capture source of channel 0, TGRA_0 to D_0 carry out the input capture operation. In addition, when the compare match/input capture is selected as the input capture source of TGRB_1, TGRB_1 carries out input capture operation. The timing is shown in Figure 10.107.

For cascade connections, be sure to synchronize settings for channels 1 and 2 when setting TCNT clearing.

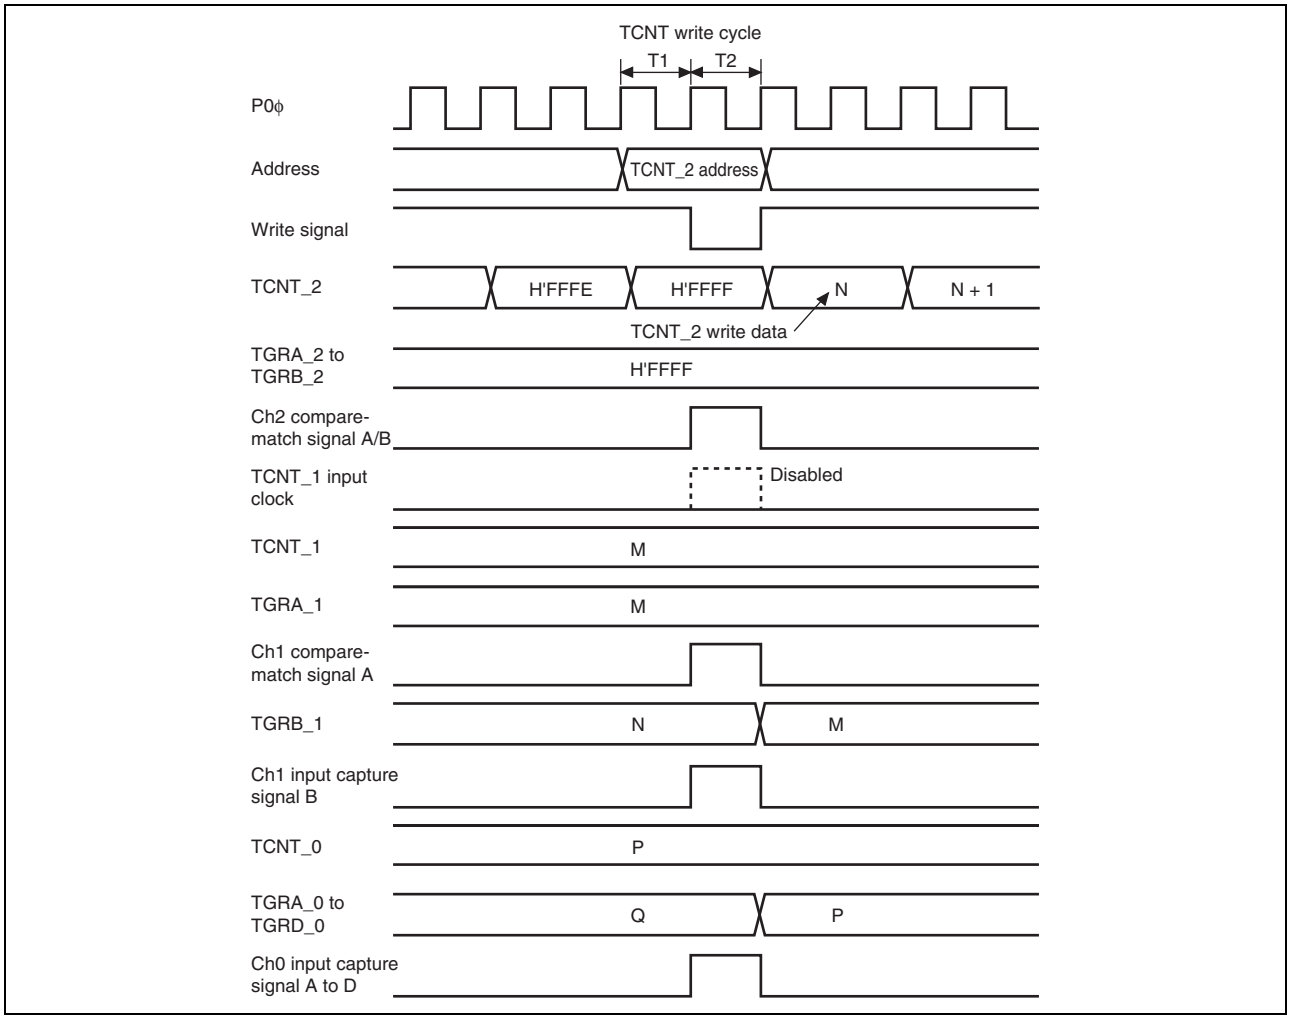

Figure 10.107 TCNT_2 Write and Overflow/Underflow Contention with Cascade Connection

10.7.13 Counter Value during Complementary PWM Mode Stop

When counting operation is suspended with TCNT_3 and TCNT_4 in complementary PWM mode, TCNT_3 has the timer dead time register (TDDR) value, and TCNT_4 is held at H'0000.

When restarting complementary PWM mode, counting begins automatically from the initialized state. This explanatory diagram is shown in Figure 10.108.

When counting begins in another operating mode, be sure that TCNT_3 and TCNT_4 are set to the initial values.

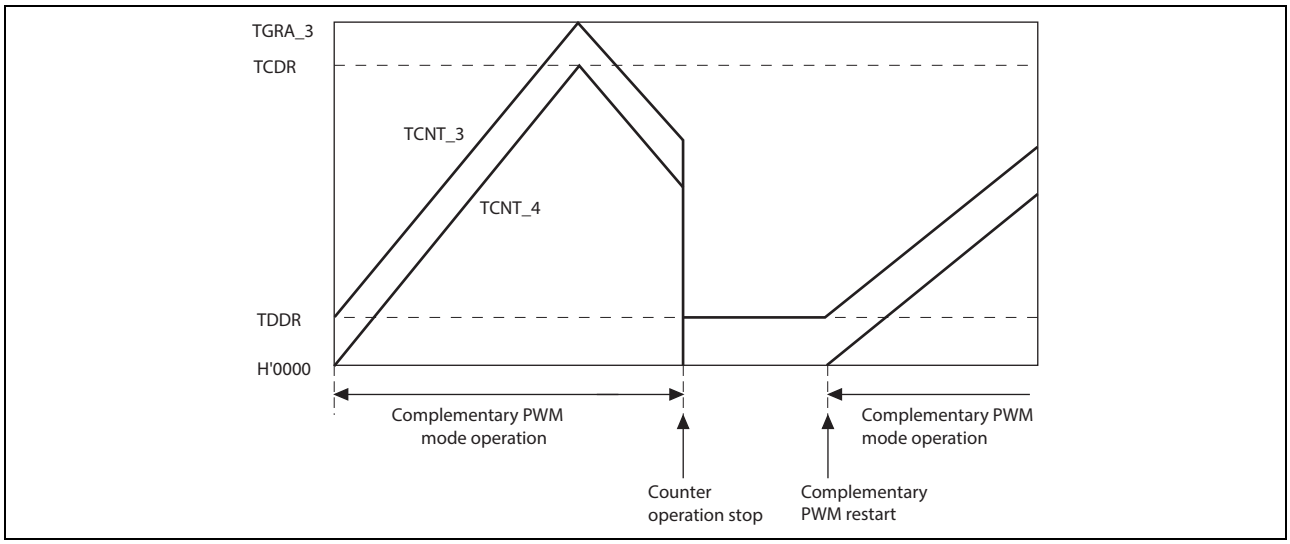

Figure 10.108 Counter Value during Complementary PWM Mode Stop

10.7.14 Buffer Operation Setting in Complementary PWM Mode

In complementary PWM mode, conduct rewrites by buffer operation for the PWM cycle setting register (TGRA_3), timer cycle data register (TCDR), and duty setting registers (TGRB_3, TGRA_4, and TGRB_4).

In complementary PWM mode, channel 3 and channel 4 buffers operate in accordance with bit settings BFA and BFB of TMDR_3. When TMDR_3's BFA bit is set to 1, TGRC_3 functions as a buffer register for TGRA_3. At the same time, TGRC_4 functions as the buffer register for TGRA_4, and TCBR functions as the TCDR's buffer register.

10.7.15 Reset Sync PWM Mode Buffer Operation and Compare Match Flag

When setting buffer operation for reset sync PWM mode, set the BFA and BFB bits of TMDR_4 to 0. The TIOC4C pin will be unable to produce its waveform output if the BFA bit of TMDR_4 is set to 1.

In reset sync PWM mode, the channel 3 and channel 4 buffers operate in accordance with the BFA and BFB bit settings of TMDR_3. For example, if the BFA bit of TMDR_3 is set to 1, TGRC_3 functions as the buffer register for TGRA_3. At the same time, TGRC_4 functions as the buffer register for TGRA_4.

The TGFC bit and TGFD bit of TSR_3 and TSR_4 are not set when TGRC_3 and TGRD_3 are operating as buffer registers.

Figure 10.109 shows an example of operations for TGR_3, TGR_4, TIOC3, and TIOC4, with TMDR_3's BFA and BFB bits set to 1, and TMDR_4's BFA and BFB bits set to 0.

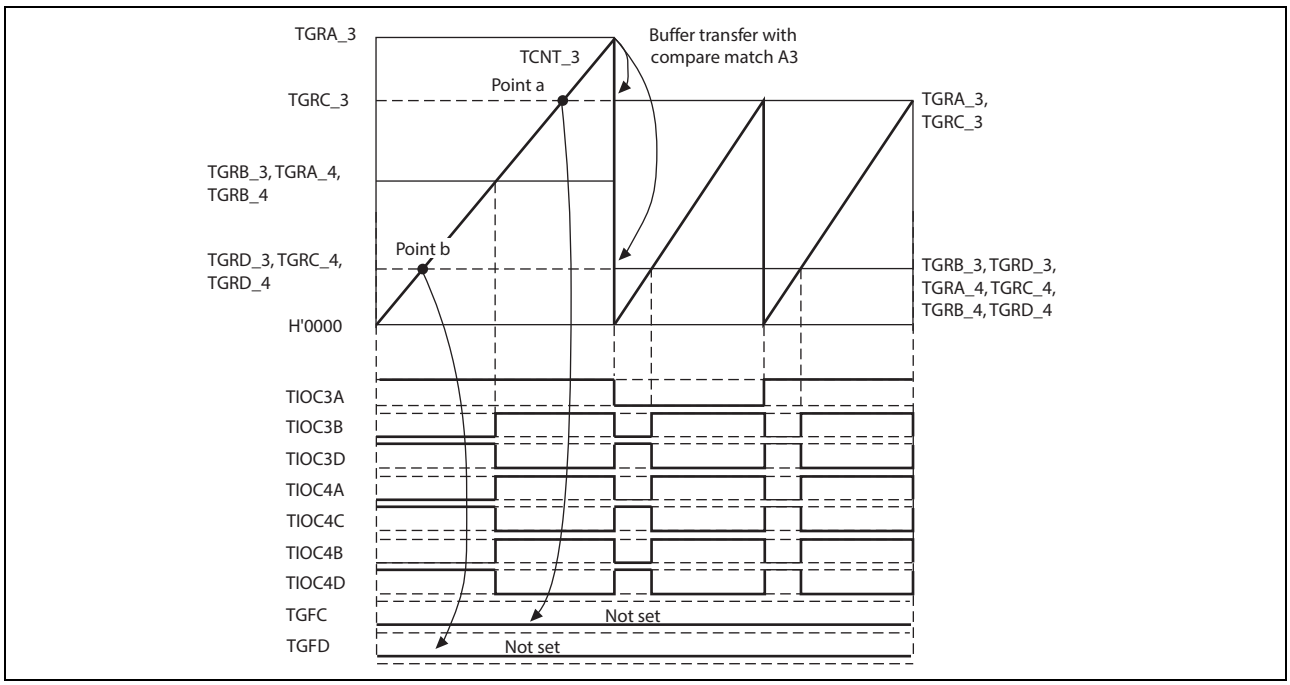

Figure 10.109 Buffer Operation and Compare-Match Flags in Reset Synchronous PWM Mode

10.7.16 Overflow Flags in Reset Synchronous PWM Mode

When set to reset synchronous PWM mode, TCNT_3 and TCNT_4 start counting when the CST3 bit of TSTR is set to 1. At this point, TCNT_4's count clock source and count edge obey the TCR_3 setting.

In reset synchronous PWM mode, with cycle register TGRA_3's set value at H'FFFF, when specifying TGR3A compare-match for the counter clear source, TCNT_3 and TCNT_4 count up to H'FFFF, then a compare-match occurs with TGRA_3, and TCNT_3 and TCNT_4 are both cleared. At this point, TSR's overflow flag TCFV bit is not set.

Figure 10.110 shows a TCFV bit operation example in reset synchronous PWM mode with a set value for cycle register TGRA_3 of H'FFFF, when a TGRA_3 compare-match has been specified without synchronous setting for the counter clear source.

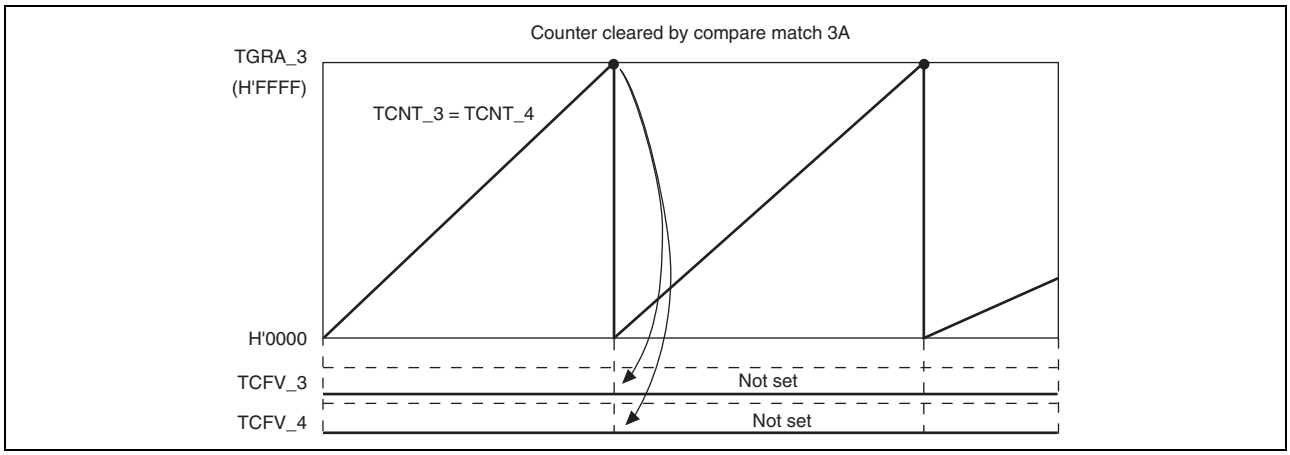

Figure 10.110 Reset Synchronous PWM Mode Overflow Flag

10.7.17 Contention between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing occur simultaneously, the TCFV/TCFU flag in TSR is not set and TCNT clearing takes precedence.

Figure 10.111 shows the operation timing when a TGR compare match is specified as the clearing source, and when H'FFFF is set in TGR.

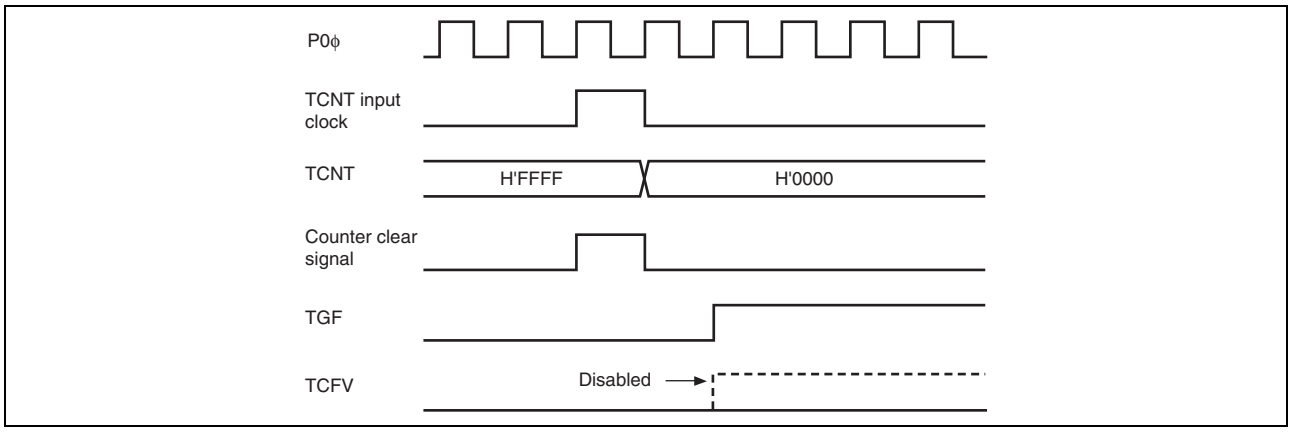

Figure 10.111 Contention between Overflow and Counter Clearing

10.7.18 Contention between TCNT Write and Overflow/Underflow

If there is an up-count or down-count in the T2 state of a TCNT write cycle, and overflow/underflow occurs, the TCNT write takes precedence and the TCFV/TCFU flag in TSR is not set.

Figure 10.112 shows the operation timing when there is contention between TCNT write and overflow.

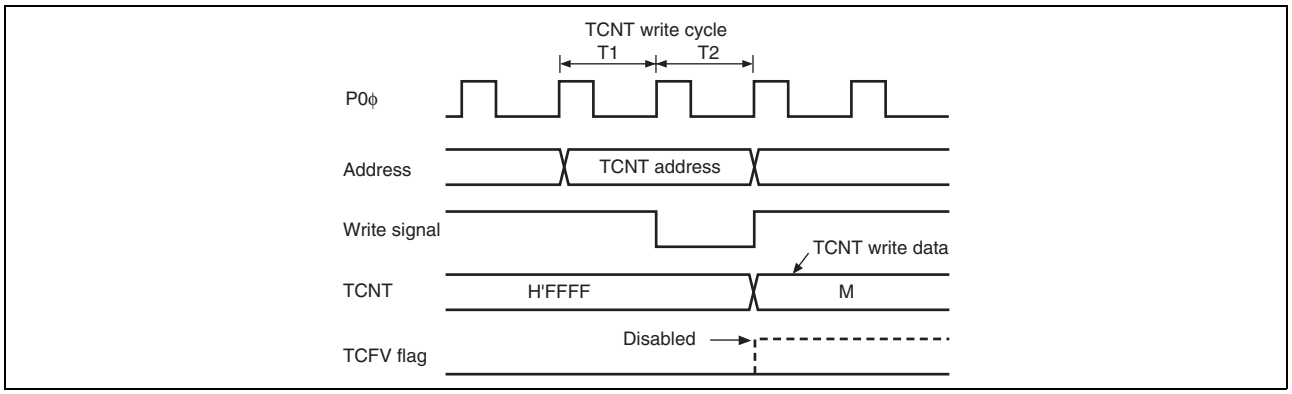

Figure 10.112 Contention between TCNT Write and Overflow

10.7.19 Cautions on Transition from Normal Operation or PWM Mode 1 to Reset-Synchronized PWM Mode

When making a transition from channel 3 or 4 normal operation or PWM mode 1 to reset-synchronized PWM mode, if the counter is halted with the output pins (TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, TIOC4D) in the high-level state, followed by the transition to reset-synchronized PWM mode and operation in that mode, the initial pin output will not be correct.

When making a transition from normal operation to reset-synchronized PWM mode, write H'11 to registers TIORH_3, TIORL_3, TIORH_4, and TIORL_4 to initialize the output pins to low level output, then set an initial register value of H'00 before making the mode transition.

When making a transition from PWM mode 1 to reset-synchronized PWM mode, first switch to normal operation, then initialize the output pins to low level output and set an initial register value of H'00 before making the transition to reset-synchronized PWM mode.

10.7.20 Output Level in Complementary PWM Mode and Reset-Synchronized PWM Mode

When channels 3 and 4 are in complementary PWM mode or reset-synchronized PWM mode, the PWM waveform output level is set with the OLSP and OLSN bits in the timer output control register (TOCR). In the case of complementary PWM mode or reset-synchronized PWM mode, TIOR should be set to H'00.

10.7.21 Interrupts in Module Standby Mode

If module standby mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the direct memory access controller activation source. Interrupts should therefore be disabled before entering module standby mode.

10.7.22 Simultaneous Capture of TCNT_1 and TCNT_2 in Cascade Connection

When timer counters 1 and 2 (TCNT_1 and TCNT_2) are operated as a 32-bit counter in cascade connection, the cascade counter value cannot be captured successfully even if input-capture input is simultaneously done to TIOC1A and TIOC2A or to TIOC1B and TIOC2B. This is because the input timing of TIOC1A and TIOC2A or of TIOC1B and TIOC2B may not be the same when external input-capture signals to be input into TCNT_1 and TCNT_2 are taken in synchronization with the internal clock. For example, TCNT_1 (the counter for upper 16 bits) does not capture the count-up value by overflow from TCNT_2 (the counter for lower 16 bits) but captures the count value before the count-up. In this case, the values of TCNT_1 = H'FFF1 and TCNT_2 = H'0000 should be transferred to TGRA_1 and TGRA_2 or to TGRB_1 and TGRB_2, but the values of TCNT_1 = H'FFF0 and TCNT_2 = H'0000 are erroneously transferred.

10.7.23 Notes on Output Waveform Control During Synchronous Counter Clearing in Complementary PWM Mode

In complementary PWM mode, when output waveform control during synchronous counter clearing is enabled (WRE in the TWCR register set to 1), the following problems may occur when condition (1) or condition (2), below, is satisfied.

- Dead time for the PWM output pins may be too short (or nonexistent).
- Active-level output from the PWM negative-phase pins may occur outside the correct active-level output interval

Condition (1): When synchronous clearing occurs in the PWM output dead time interval within initial output suppression interval (10) (Figure 10.113).

Condition (2): When synchronous clearing occurs within initial output suppression interval (10) or (11) and TGRB_3 ≤ TDDR, TGRA_4 ≤ TDDR, or TGRB_4 ≤ TDDR is true (Figure 10.114)

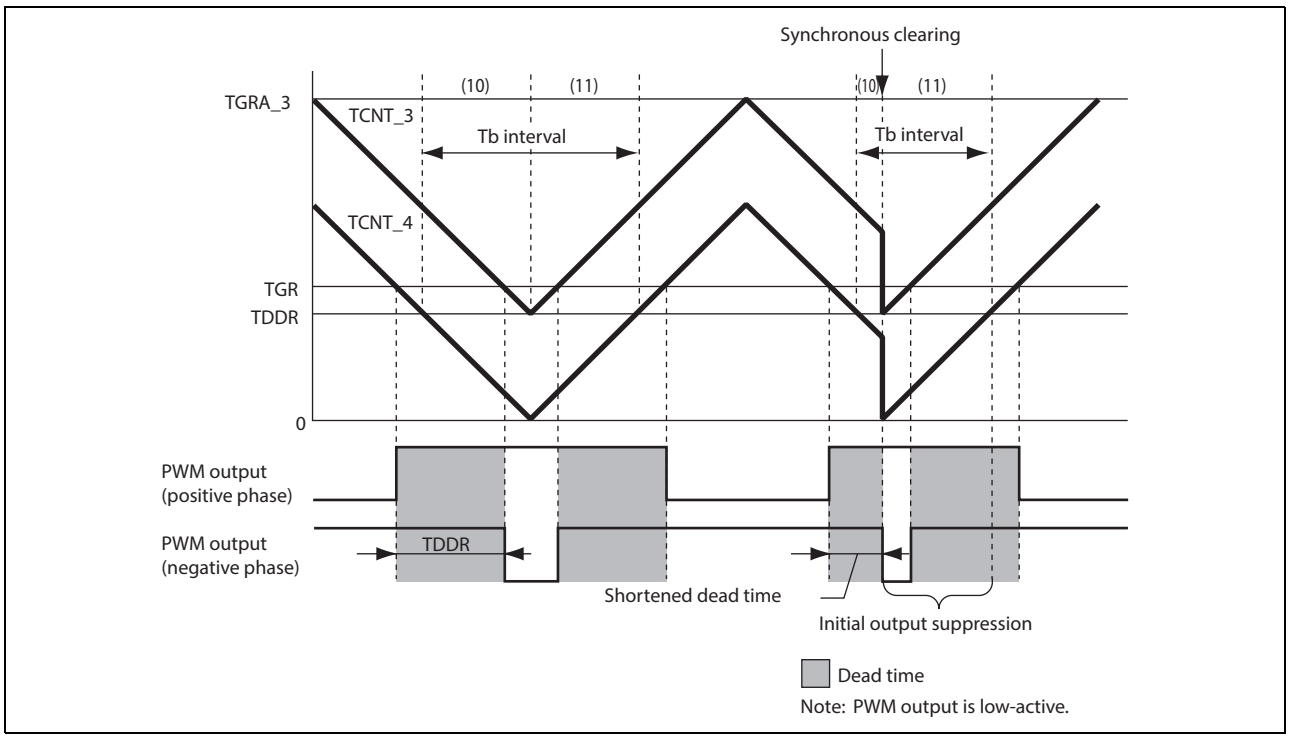

Figure 10.113 Condition (1) Synchronous Clearing Example

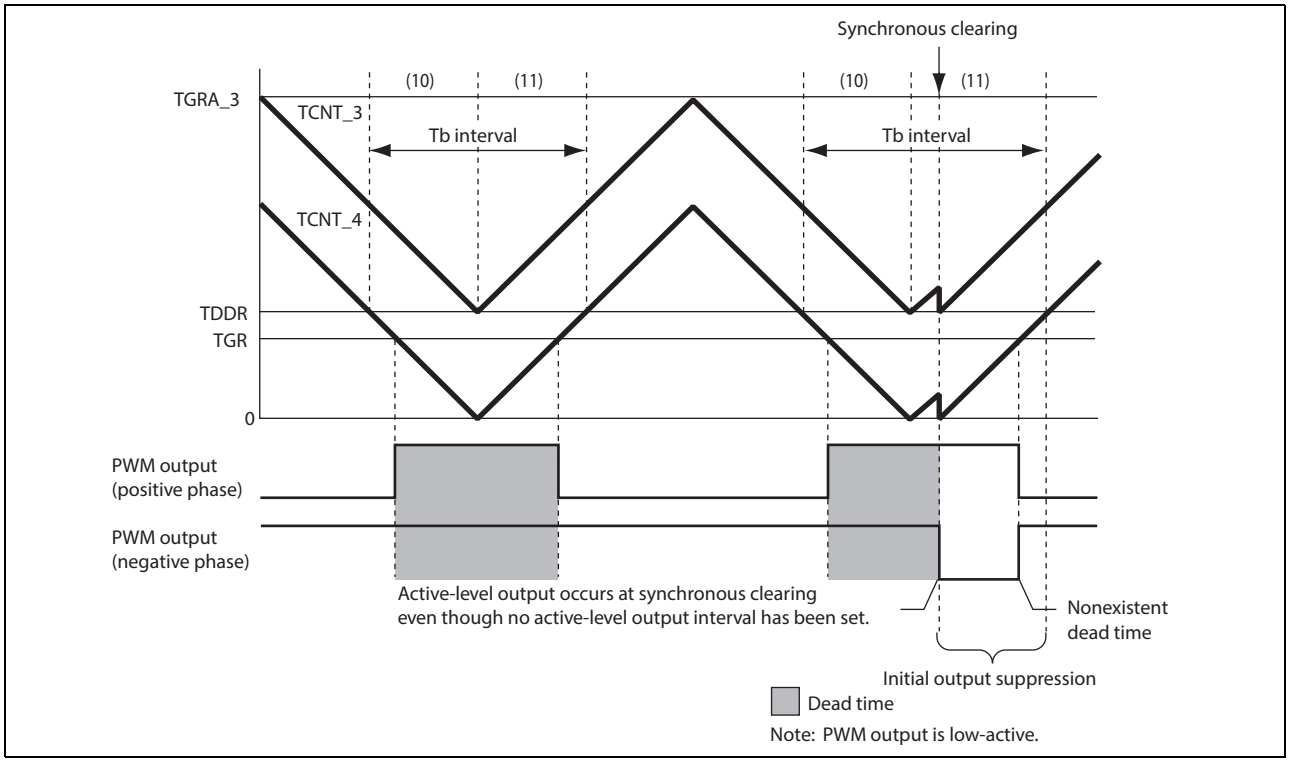

Figure 10.114 Condition (2) Synchronous Clearing Example

The following workaround can be used to avoid these problems.

When using synchronous clearing, make sure to set compare registers TGRB_3, TGRA_4, and TGRB_4 to a value twice or more the setting of dead time data register TDDR.

10.8 Output Pin Initialization for Multi-Function Timer Pulse Unit 2

10.8.1 Operating Modes

This module has the following six operating modes. Waveform output is possible in all of these modes.

- Normal mode (channels 0 to 4)
- PWM mode 1 (channels 0 to 4)
- PWM mode 2 (channels 0 to 2)
- Phase counting modes 1 to 4 (channels 1 and 2)
- Complementary PWM mode (channels 3 and 4)
- Reset-synchronized PWM mode (channels 3 and 4)

The output pin initialization method for each of these modes is described in this section.

10.8.2 Reset Start Operation

The output pins of this module (TIOC*) are initialized low by a power-on reset or in deep standby mode. Since the pin functions are selected using the general I/O ports, when the general I/O port is set, the pin states at that point are output to the ports. When this module output is selected by the general I/O port immediately after a reset, the initial output level, low, is output directly at the port. When the active level is low, the system will operate at this point, and therefore the general
I/O port setting should be made after the initialization of the output pins is completed.

Note: Channel number and port notation are substituted for *.

10.8.3 Operation in Case of Re-Setting Due to Error during Operation, etc.

If an error occurs during operation of this module, the module output should be cut by the system. Cutoff is performed by switching the pin output to port output with the general I/O port and outputting the inverse of the active level. The pin initialization procedures for re-setting due to an error during operation, etc., and the procedures for restarting in a different mode after re-setting, are shown below.

This module has six operating modes, as stated above. There are thus 36 mode transition combinations, but some transitions are not available with certain channel and mode combinations. Possible mode transition combinations are shown in Table 10.57.

Table 10.57 Mode Transition Combinations

	After					
Before	**Normal**	**PWM1**	**PWM2**	**PCM**	**CPWM**	**RPWM**
Normal	(1)	(2)	(3)	(4)	(5)	(6)

PWM2	(13)	(14)	(15)	(16)	None	None
PCM	(17)	(18)	(19)	(20)	None	None
CPWM	(21)	(22)	None	None	(23) (24)	(25)
RPWM	(26)	(27)	None	None	(28)	(29)

[Legend]
Normal: Normal mode
PWM1: PWM mode 1
PWM2: PWM mode 2
PCM: Phase counting modes 1 to 4
CPWM: Complementary PWM mode
RPWM: Reset-synchronized PWM mode

10.8.4 Overview of Initialization Procedures and Mode Transitions in Case of Error during Operation, etc.

- When making a transition to a mode (Normal, PWM1, PWM2, PCM) in which the pin output level is selected by the timer I/O control register (TIOR) setting, initialize the pins by means of a TIOR setting.
- In PWM mode 1, since a waveform is not output to the TIOC*B (TIOC *D) pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 1.
- In PWM mode 2, since a waveform is not output to the cycle register pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 2.
- In normal mode or PWM mode 2, if TGRC and TGRD operate as buffer registers, setting TIOR will not initialize the buffer register pins. If initialization is required, clear buffer mode, carry out initialization, then set buffer mode again.
- In PWM mode 1, if either TGRC or TGRD operates as a buffer register, setting TIOR will not initialize the TGRC pin. To initialize the TGRC pin, clear buffer mode, carry out initialization, then set buffer mode again.
- When making a transition to a mode (CPWM, RPWM) in which the pin output level is selected by the timer output control register (TOCR) setting, switch to normal mode and perform initialization with TIOR, then restore TIOR to its initial value, and temporarily disable channel 3 and 4 output with the timer output master enable register (TOER). Then operate the unit in accordance with the mode setting procedure (TOCR setting, TMDR setting, TOER setting).

Note: Channel number is substituted for * indicated in this article.

Pin initialization procedures are described below for the numbered combinations in Table 10.57. The active level is assumed to be low.

(1) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Normal Mode

Figure 10.115 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in normal mode after re-setting.

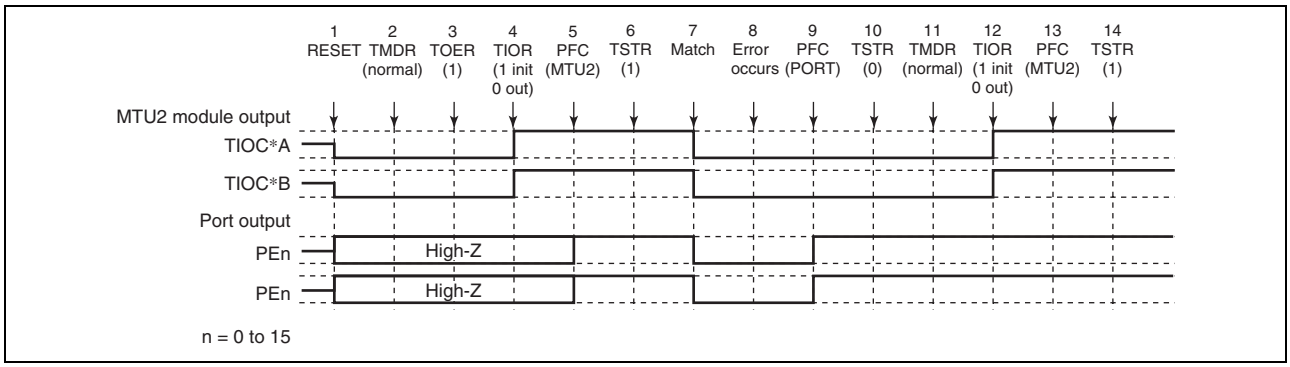

Figure 10.115 Error Occurrence in Normal Mode, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. After a reset, the TMDR setting is for normal mode.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
5. Set the multi-function timer pulse unit 2 output with the general I/O port.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the general I/O port and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Not necessary when restarting in normal mode.
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(2) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 10.116 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 1 after re-setting.

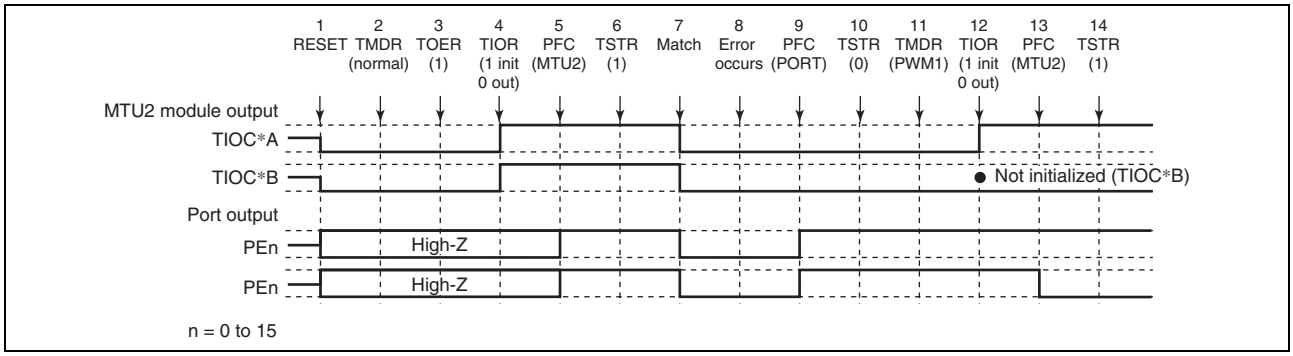

Figure 10.116 Error Occurrence in Normal Mode, Recovery in PWM Mode 1

1 to 10 are the same as in Figure 10.115.

11. Set PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC*B side is not initialized. If initialization is required, initialize in normal mode, and then switch to PWM mode 1.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(3) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 10.117 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 2 after re-setting.

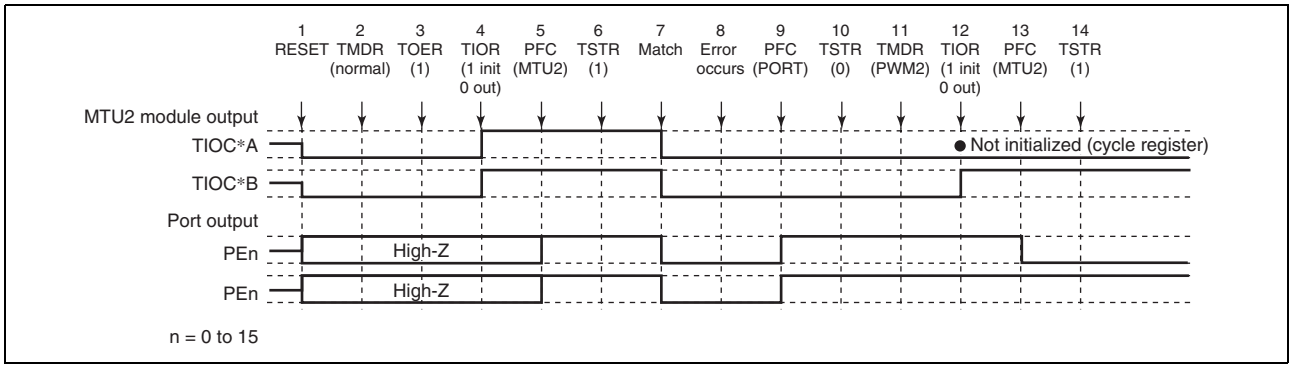

Figure 10.117 Error Occurrence in Normal Mode, Recovery in PWM Mode 2

1 to 10 are the same as in Figure 10.115.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized. If initialization is required, initialize in normal mode, and then switch to PWM mode 2.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

(4) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 10.118 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in phase counting mode after re-setting.

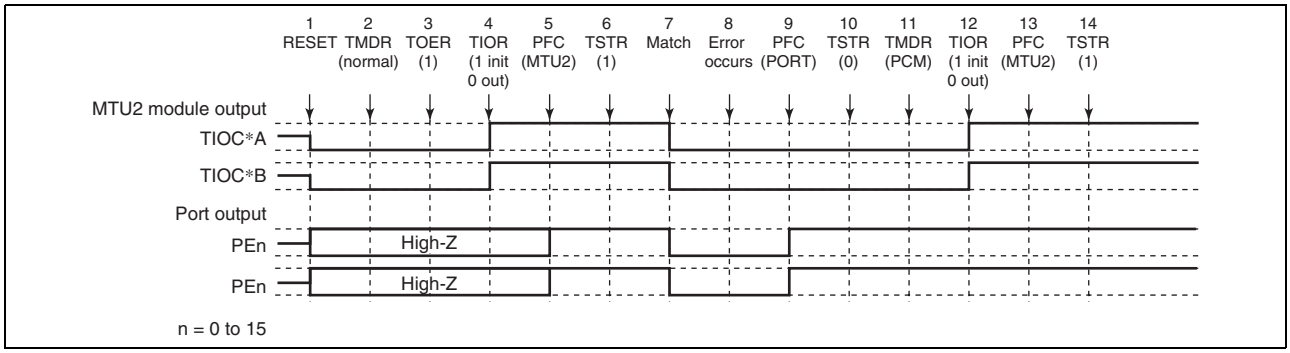

Figure 10.118 Error Occurrence in Normal Mode, Recovery in Phase Counting Mode

1 to 10 are the same as in Figure 10.115.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

Note: Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

(5) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 10.119 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in complementary PWM mode after re-setting.

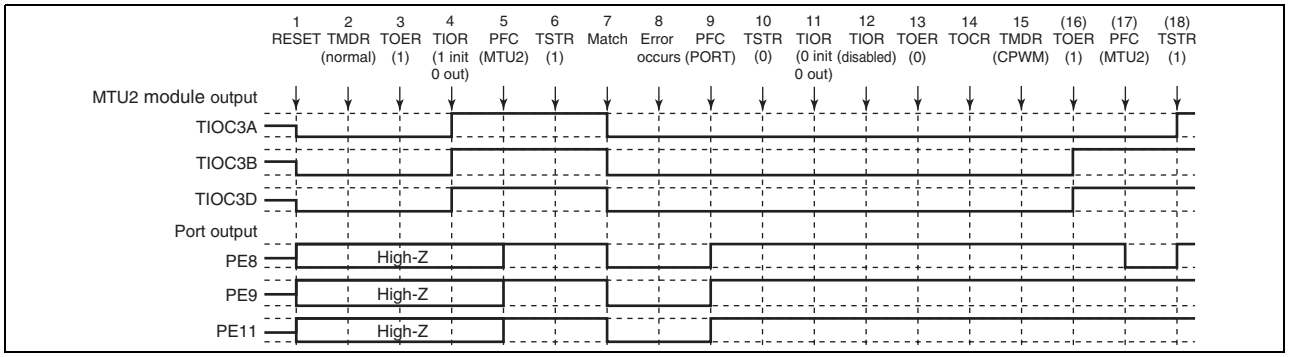

Figure 10.119 Error Occurrence in Normal Mode, Recovery in Complementary PWM Mode

1 to 10 are the same as in Figure 10.115.

11. Initialize the normal mode waveform generation section with TIOR.
12. Disable operation of the normal mode waveform generation section with TIOR.
13. Disable channel 3 and 4 output with TOER.
14. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
15. Set complementary PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set the multi-function timer pulse unit 2 output with the general I/O port.
18. Operation is restarted by TSTR.

(6) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 10.120 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in reset-synchronized PWM mode after re-setting.

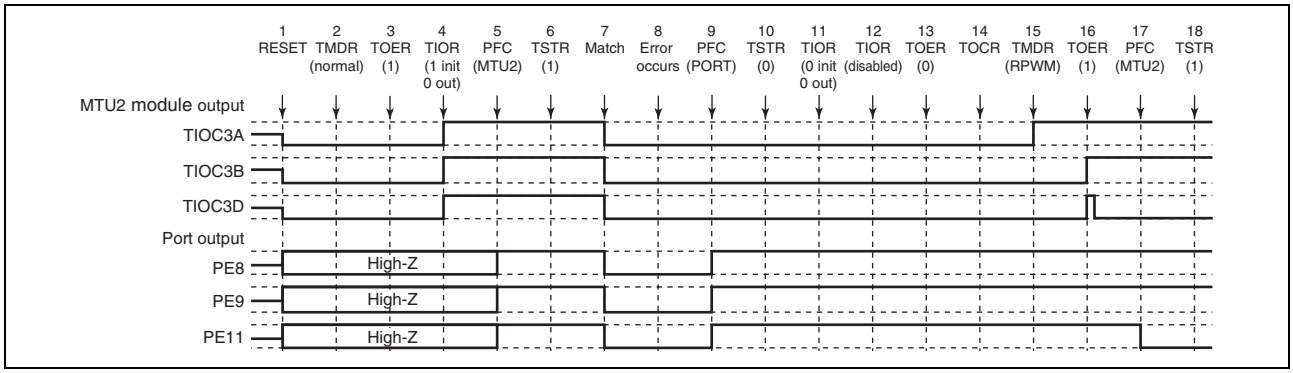

Figure 10.120 Error Occurrence in Normal Mode, Recovery in Reset-Synchronized PWM Mode

1 to 13 are the same as in Figure 10.115.

14. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
15. Set reset-synchronized PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set the multi-function timer pulse unit 2 output with the general I/O port.
18. Operation is restarted by TSTR.

(7) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Normal Mode

Figure 10.121 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in normal mode after re-setting.

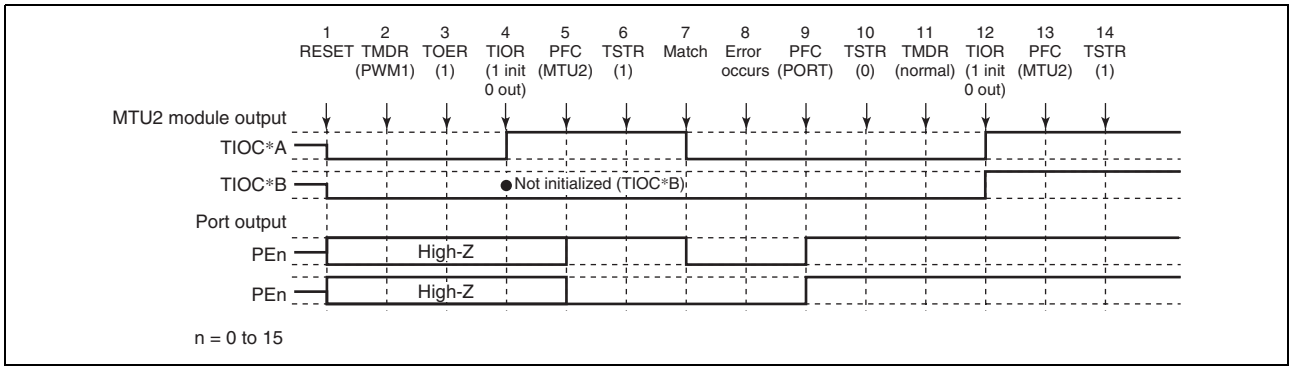

Figure 10.121 Error Occurrence in PWM Mode 1, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. Set PWM mode 1.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 1, the TIOC*B side is not initialized.)
5. Set the multi-function timer pulse unit 2 output with the general I/O port.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the general I/O port and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Set normal mode.
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(8) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 1

Figure 10.122 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 1 after re-setting.

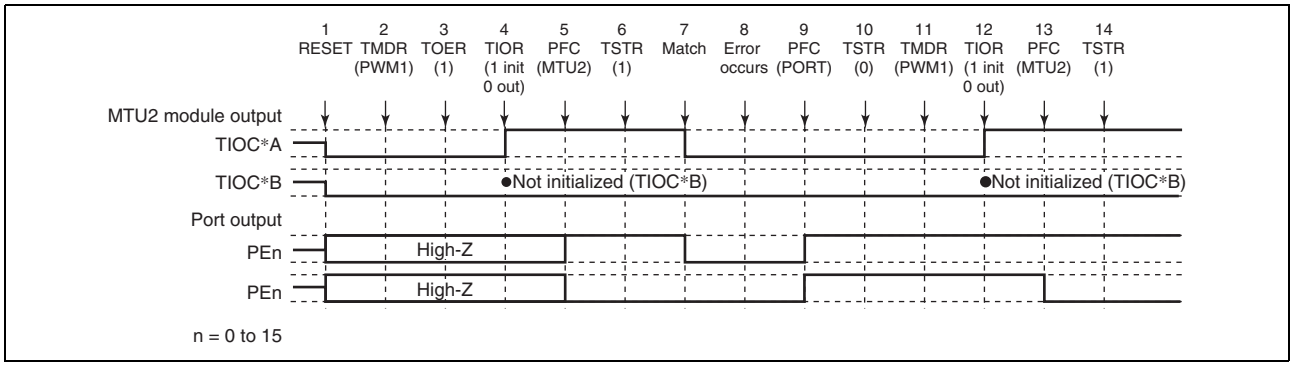

Figure 10.122 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 1

1 to 10 are the same as in Figure 10.121.

11. Not necessary when restarting in PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC*B side is not initialized.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(9) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 2

Figure 10.123 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 2 after re-setting.

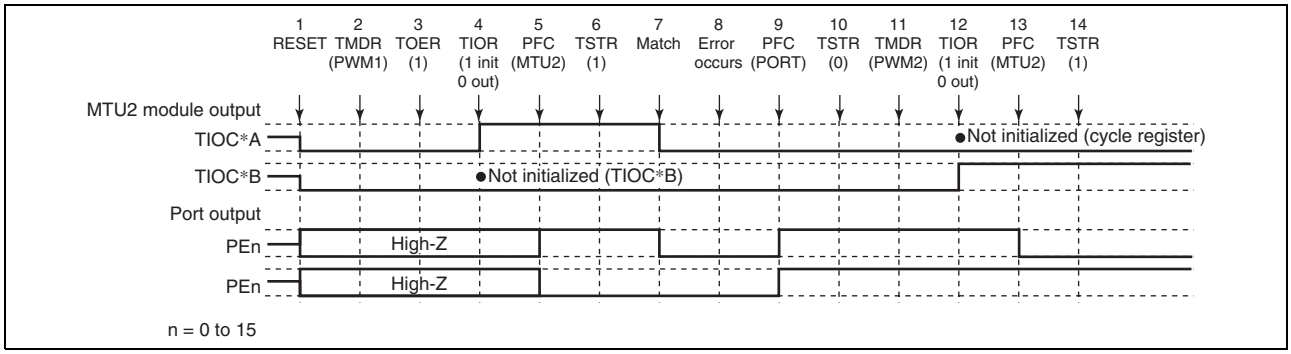

Figure 10.123 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 2

1 to 10 are the same as in Figure 10.121.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

(10) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Phase Counting Mode

Figure 10.124 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in phase counting mode after re-setting.

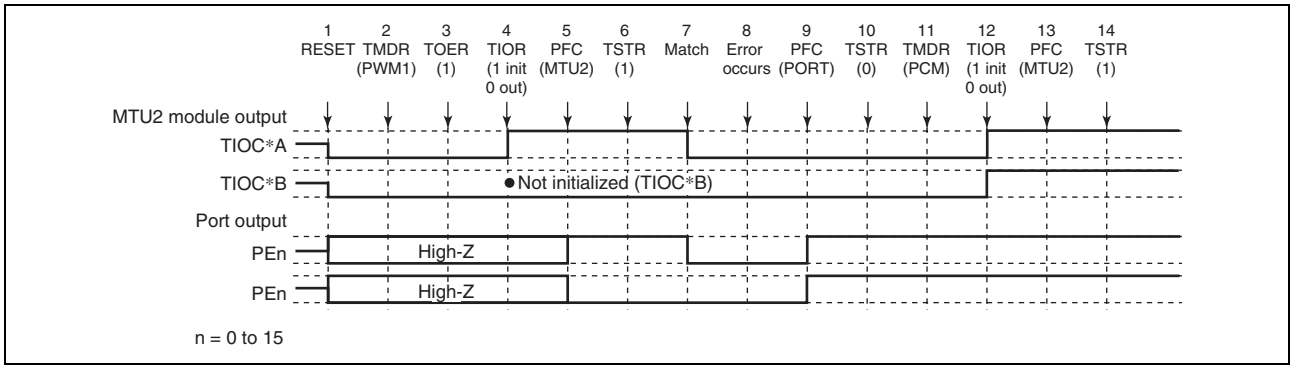

Figure 10.124 Error Occurrence in PWM Mode 1, Recovery in Phase Counting Mode

1 to 10 are the same as in Figure 10.121.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

Note: Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

(11) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Complementary PWM Mode

Figure 10.125 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in complementary PWM mode after re-setting.

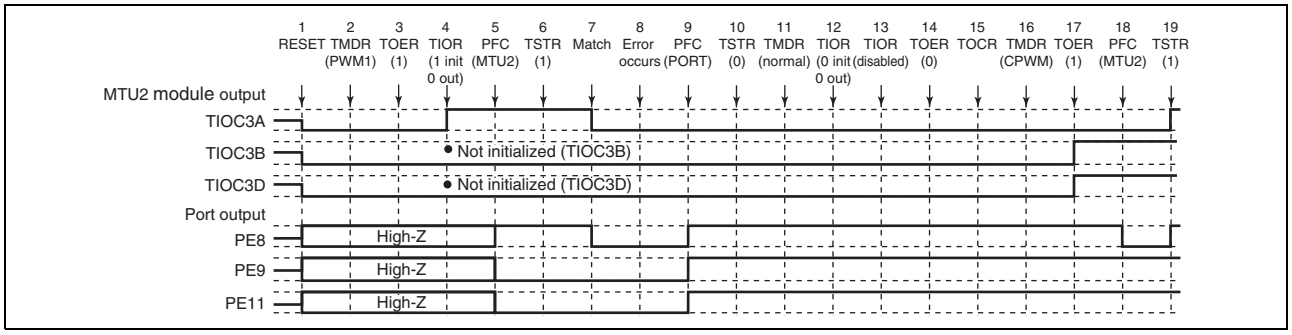

Figure 10.125 Error Occurrence in PWM Mode 1, Recovery in Complementary PWM Mode

1 to 10 are the same as in Figure 10.121.

11. Set normal mode for initialization of the normal mode waveform generation section.
12. Initialize the PWM mode 1 waveform generation section with TIOR.
13. Disable operation of the PWM mode 1 waveform generation section with TIOR.
14. Disable channel 3 and 4 output with TOER.
15. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
16. Set complementary PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set the multi-function timer pulse unit 2 output with the general I/O port.
19. Operation is restarted by TSTR.

(12) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 10.126 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in reset-synchronized PWM mode after re-setting.

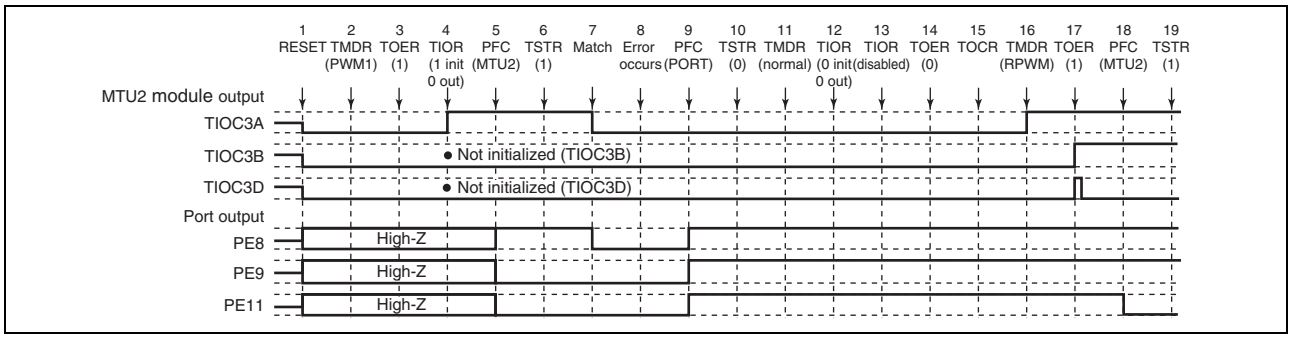

Figure 10.126 Error Occurrence in PWM Mode 1, Recovery in Reset-Synchronized PWM Mode

1 to 14 are the same as in Figure 10.125.

15. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
16. Set reset-synchronized PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set the multi-function timer pulse unit 2 output with the general I/O port.
19. Operation is restarted by TSTR.

(13) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Normal Mode

Figure 10.127 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in normal mode after re-setting.

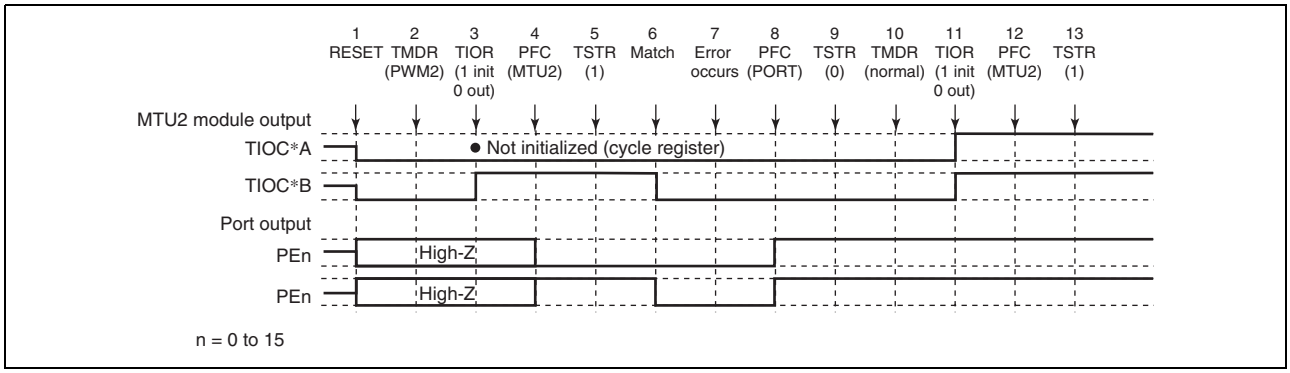

Figure 10.127 Error Occurrence in PWM Mode 2, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. Set PWM mode 2.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 2, the cycle register pins are not initialized. In the example, TIOC *A is the cycle register.)
4. Set the multi-function timer pulse unit 2 output with the general I/O port.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the general I/O port and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set normal mode.
11. Initialize the pins with TIOR.
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(14) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 1

Figure 10.128 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 1 after re-setting.

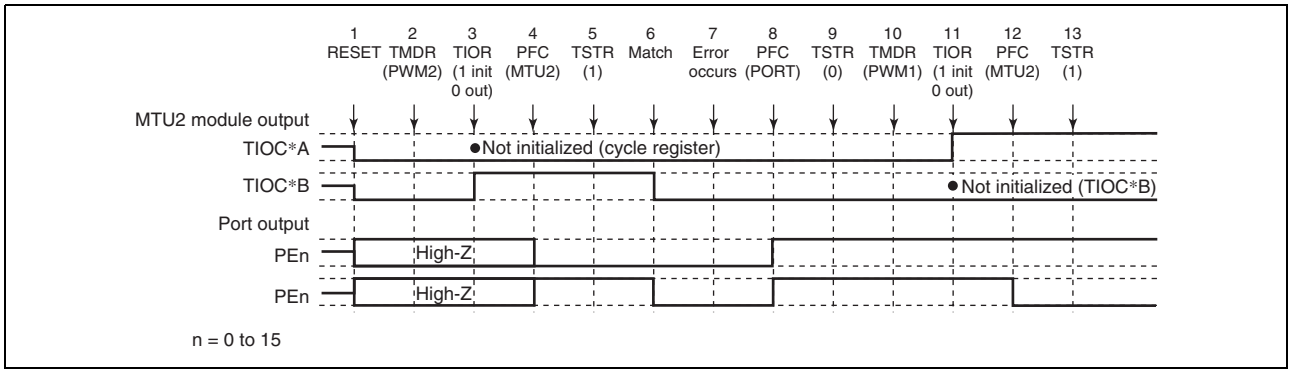

Figure 10.128 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 1

1 to 9 are the same as in Figure 10.127.

10. Set PWM mode 1.
11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC*B side is not initialized.)
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(15) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 2

Figure 10.129 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 2 after re-setting.

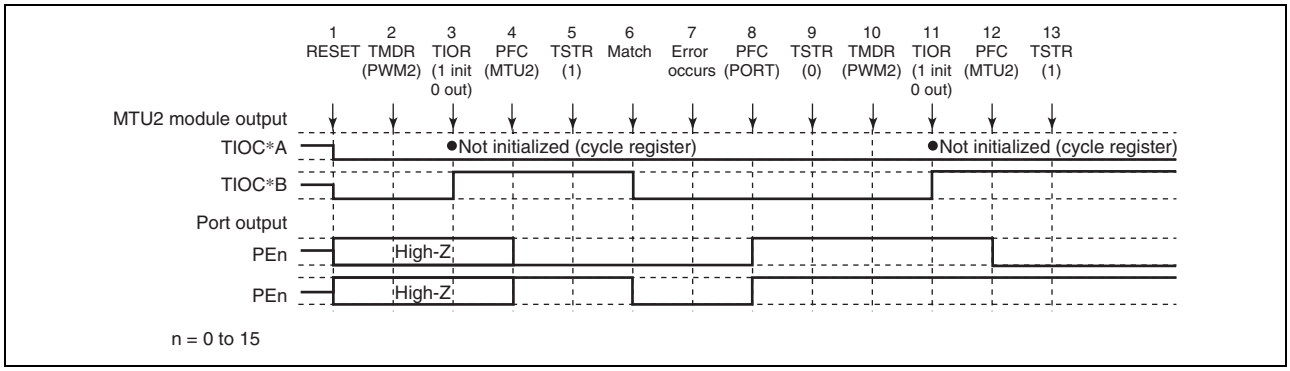

Figure 10.129 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 2

1 to 9 are the same as in Figure 10.127.

10. Not necessary when restarting in PWM mode 2.
11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(16) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Phase Counting Mode

Figure 10.130 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in phase counting mode after re-setting.

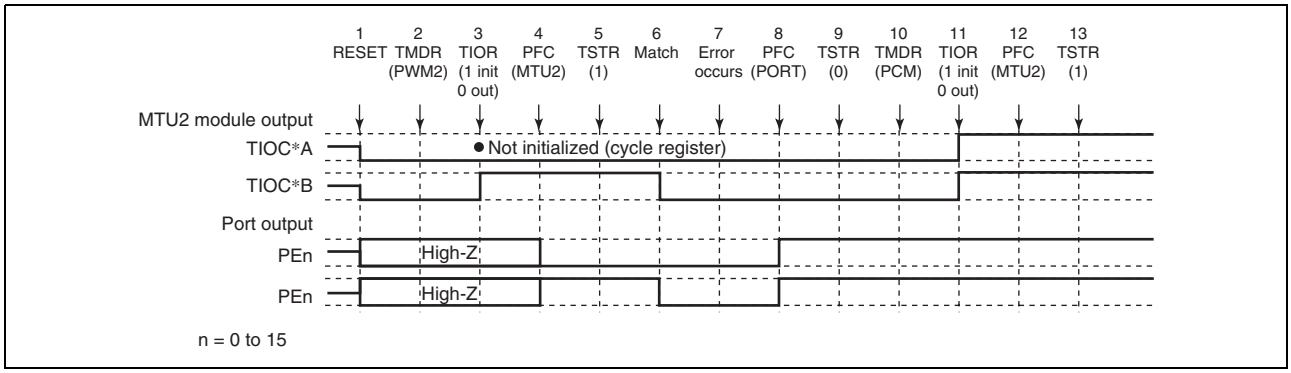

Figure 10.130 Error Occurrence in PWM Mode 2, Recovery in Phase Counting Mode

1 to 9 are the same as in Figure 10.127.

10. Set phase counting mode.
11. Initialize the pins with TIOR.
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(17) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Normal Mode

Figure 10.131 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in normal mode after re-setting.

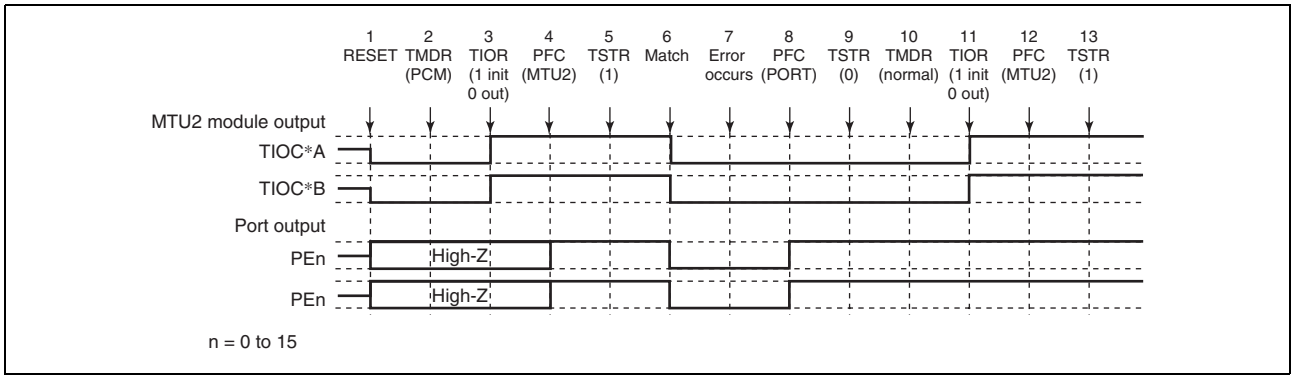

Figure 10.131 Error Occurrence in Phase Counting Mode, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. Set phase counting mode.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
4. Set the multi-function timer pulse unit 2 output with the general I/O port.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the general I/O port and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set in normal mode.
11. Initialize the pins with TIOR.
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(18) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 10.132 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 1 after re-setting.

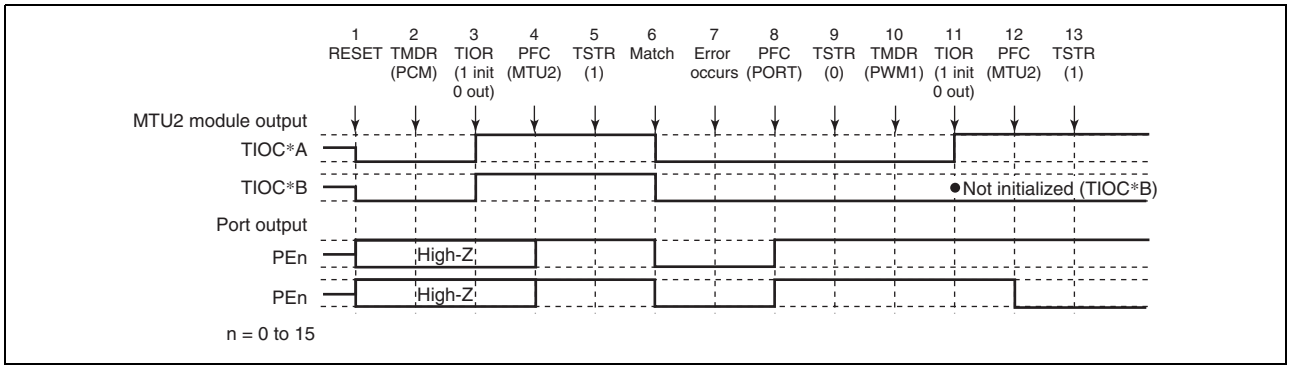

Figure 10.132 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 1

1 to 9 are the same as in Figure 10.131.

10. Set PWM mode 1.
11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC *B side is not initialized.)
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(19) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 10.133 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 2 after re-setting.

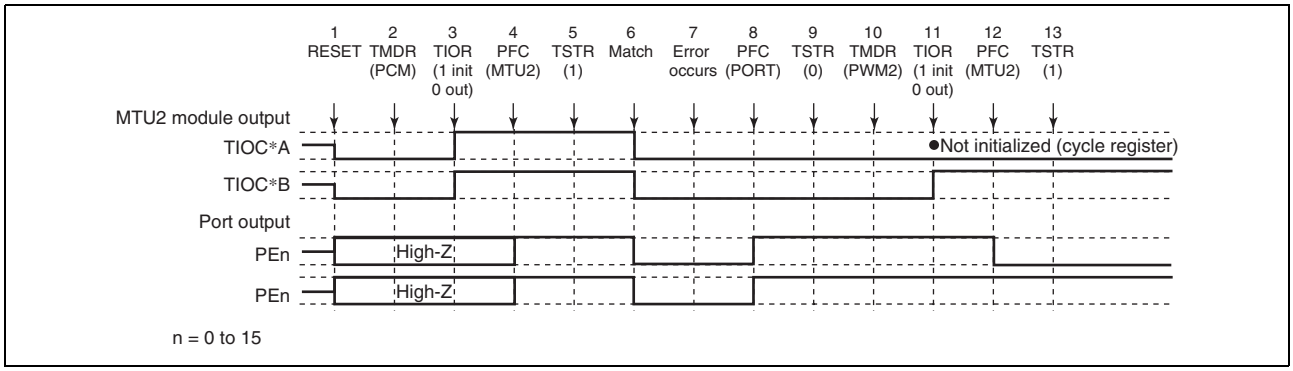

Figure 10.133 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 2

1 to 9 are the same as in Figure 10.131.

10. Set PWM mode 2.
11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(20) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 10.134 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in phase counting mode after re-setting.

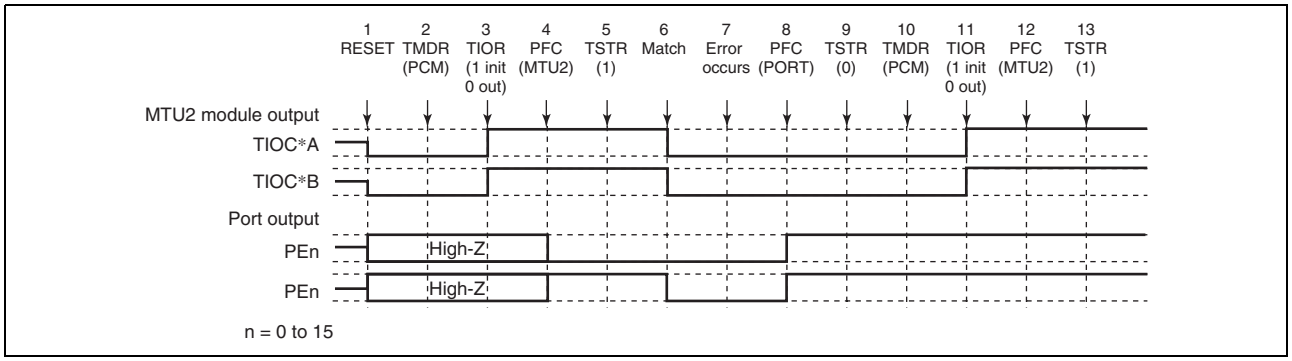

Figure 10.134 Error Occurrence in Phase Counting Mode, Recovery in Phase Counting Mode

1 to 9 are the same as in Figure 10.131.

10. Not necessary when restarting in phase counting mode.
11. Initialize the pins with TIOR.
12. Set the multi-function timer pulse unit 2 output with the general I/O port.
13. Operation is restarted by TSTR.

(21) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 10.135 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in normal mode after re-setting.

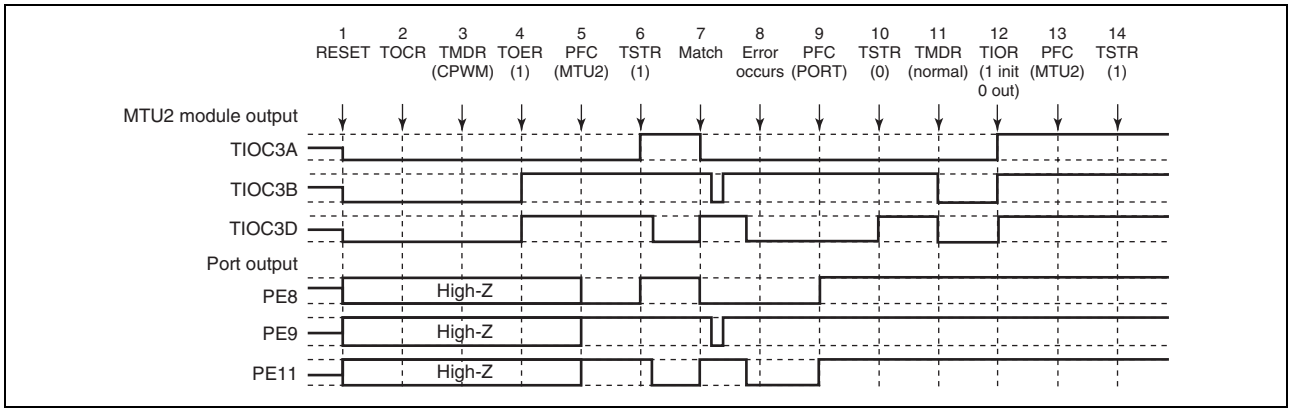

Figure 10.135 Error Occurrence in Complementary PWM Mode, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
3. Set complementary PWM.
4. Enable channel 3 and 4 output with TOER.
5. Set the multi-function timer pulse unit 2 output with the general I/O port.
6. The count operation is started by TSTR.
7. The complementary PWM waveform is output on compare-match occurrence.
8. An error occurs.
9. Set port output with the general I/O port and output the inverse of the active level.
10. The count operation is stopped by TSTR. (This module outputs the same value as the complementary PWM output initial value.)
11. Set normal mode. (This module outputs a low-level signal.)
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(22) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 10.136 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in PWM mode 1 after re-setting.

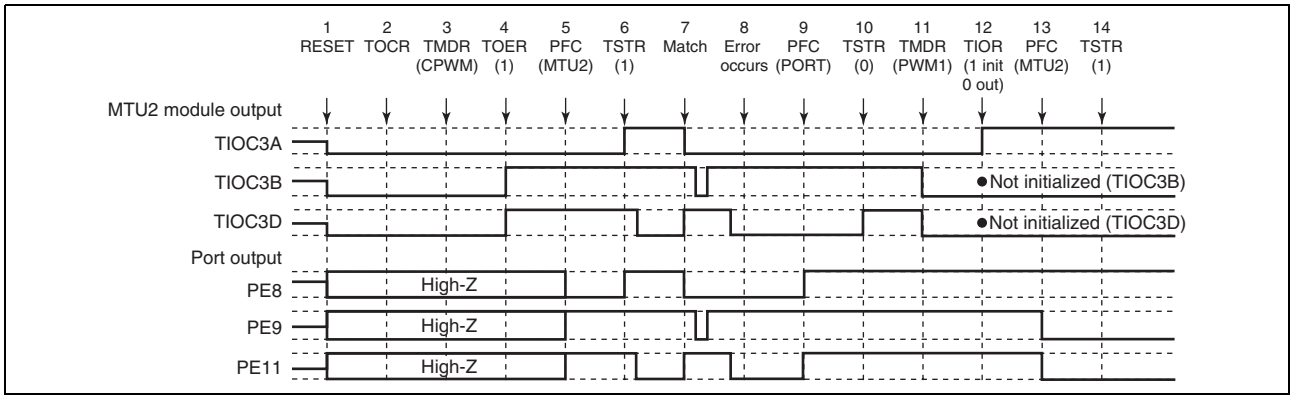

Figure 10.136 Error Occurrence in Complementary PWM Mode, Recovery in PWM Mode 1

1 to 10 are the same as in Figure 10.135.

11. Set PWM mode 1. (This module outputs a low-level signal.)
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC *B side is not initialized.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(23) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 10.137 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using the cycle and duty settings at the time the counter was stopped).

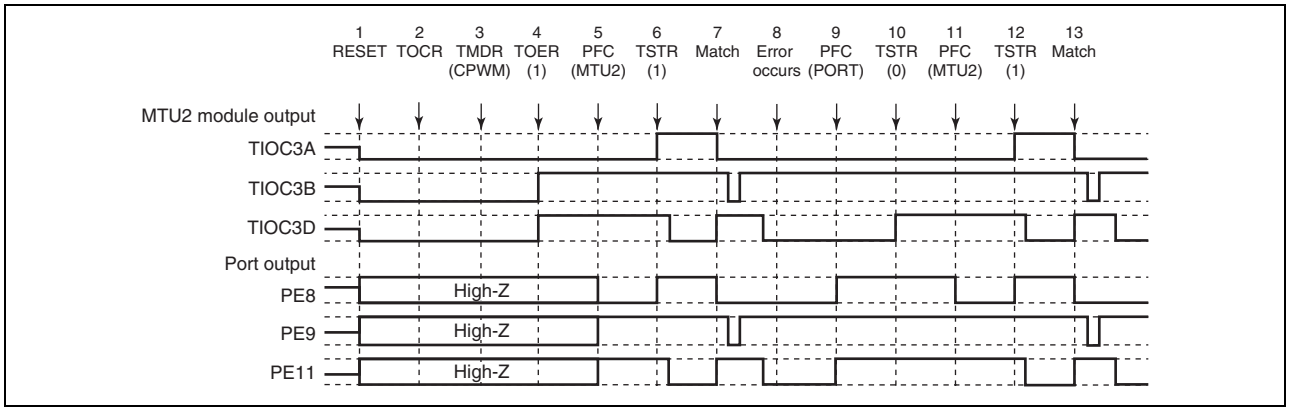

Figure 10.137 Error Occurrence in Complementary PWM Mode, Recovery in Complementary PWM Mode

1 to 10 are the same as in Figure 10.135.

11. Set the multi-function timer pulse unit 2 output with the general I/O port.
12. Operation is restarted by TSTR.
13. The complementary PWM waveform is output on compare-match occurrence.

(24) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 10.138 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using completely new cycle and duty settings).

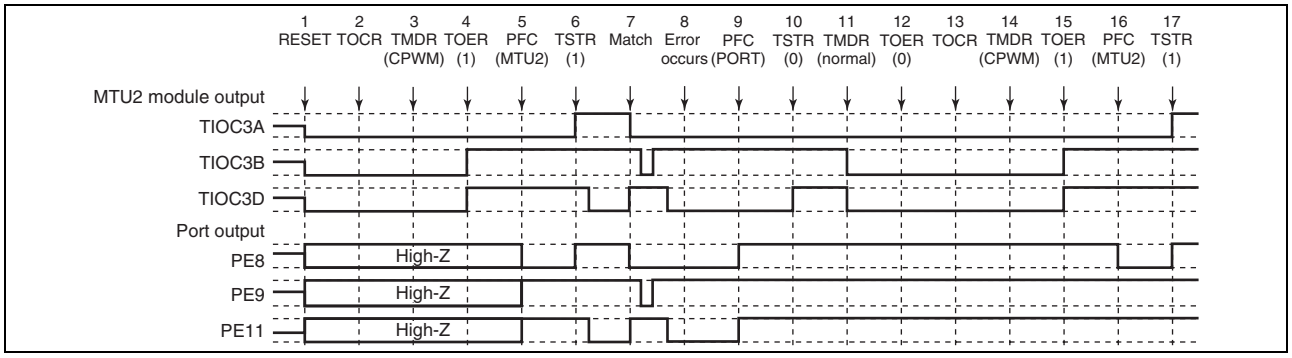

Figure 10.138 Error Occurrence in Complementary PWM Mode, Recovery in Complementary PWM Mode

1 to 10 are the same as in Figure 10.135.

11. Set normal mode and make new settings. (This module outputs a low-level signal.)
12. Disable channel 3 and 4 output with TOER.
13. Select the complementary PWM mode output level and cyclic output enabling/disabling with TOCR.
14. Set complementary PWM.
15. Enable channel 3 and 4 output with TOER.
16. Set the multi-function timer pulse unit 2 output with the general I/O port.
17. Operation is restarted by TSTR.

(25) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 10.139 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in reset-synchronized PWM mode.

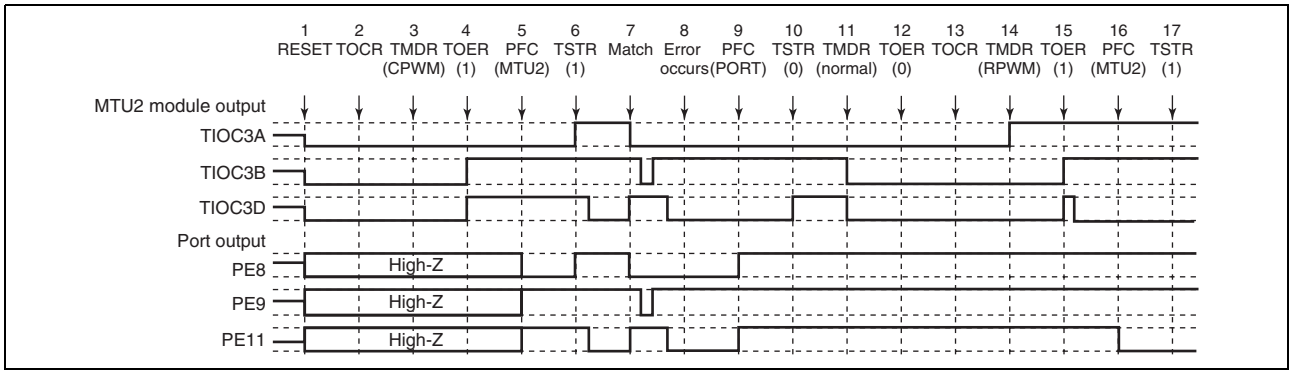

Figure 10.139 Error Occurrence in Complementary PWM Mode, Recovery in Reset-Synchronized PWM Mode

1 to 10 are the same as in Figure 10.135.

11. Set normal mode. (This module outputs a low-level signal.)
12. Disable channel 3 and 4 output with TOER.
13. Select the reset-synchronized PWM mode output level and cyclic output enabling/disabling with TOCR.
14. Set reset-synchronized PWM.
15. Enable channel 3 and 4 output with TOER.
16. Set the multi-function timer pulse unit 2 output with the general I/O port.
17. Operation is restarted by TSTR.

(26) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 10.140 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in normal mode after re-setting.

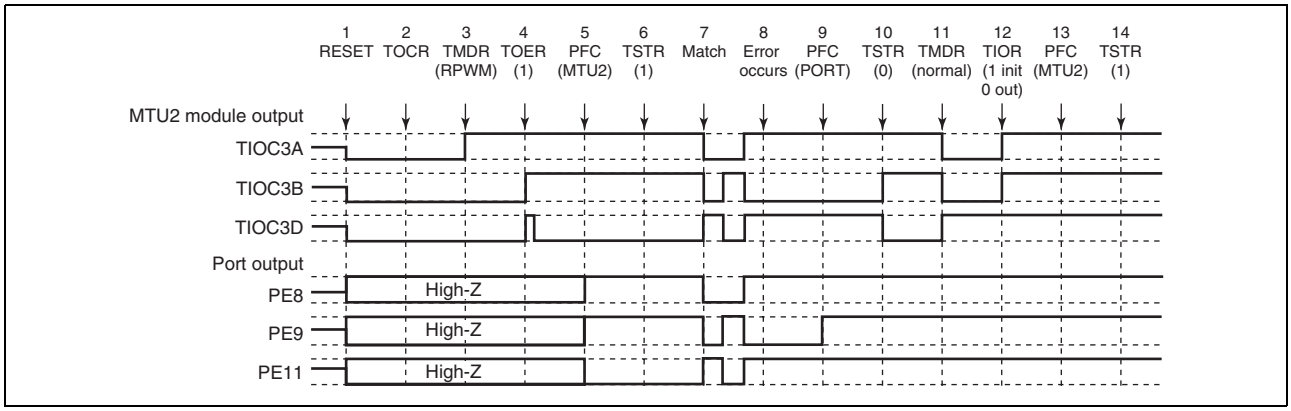

Figure 10.140 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Normal Mode

1. After a reset, the module output is low and ports are in the high-impedance state.
2. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
3. Set reset-synchronized PWM.
4. Enable channel 3 and 4 output with TOER.
5. Set the multi-function timer pulse unit 2 output with the general I/O port.
6. The count operation is started by TSTR.
7. The reset-synchronized PWM waveform is output on compare-match occurrence.
8. An error occurs.
9. Set port output with the general I/O port and output the inverse of the active level.
10. The count operation is stopped by TSTR. (This module outputs the same value as the reset-synchronized PWM output initial value.)
11. Set normal mode. (The positive phase output from this module is low, and negative phase output is high.)
12. Initialize the pins with TIOR.
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(27) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 10.141 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in PWM mode 1 after re-setting.

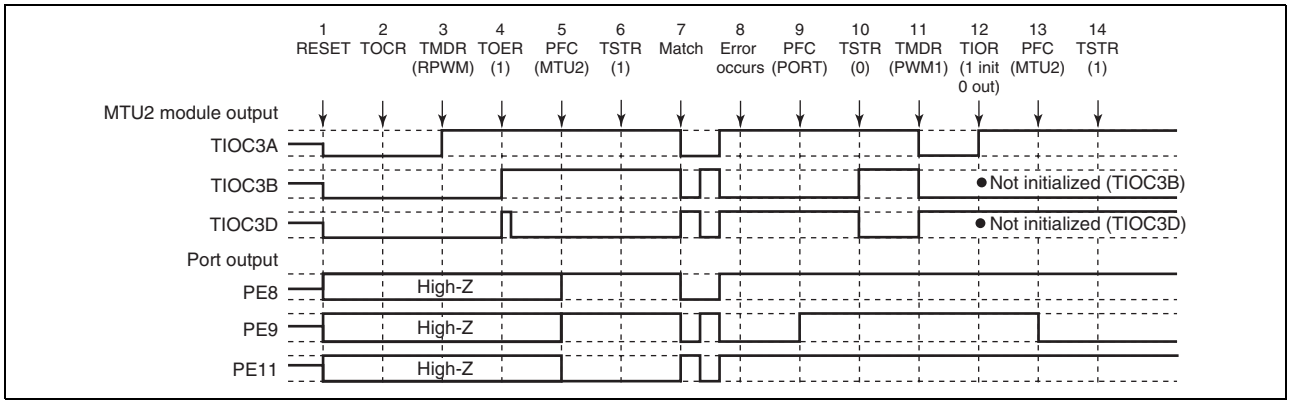

Figure 10.141 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in PWM Mode 1

1 to 10 are the same as in Figure 10.140.

11. Set PWM mode 1. (The positive phase output from this module is low, and negative phase output is high.)
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC *B side is not initialized.)
13. Set the multi-function timer pulse unit 2 output with the general I/O port.
14. Operation is restarted by TSTR.

(28) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 10.142 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in complementary PWM mode after re-setting.

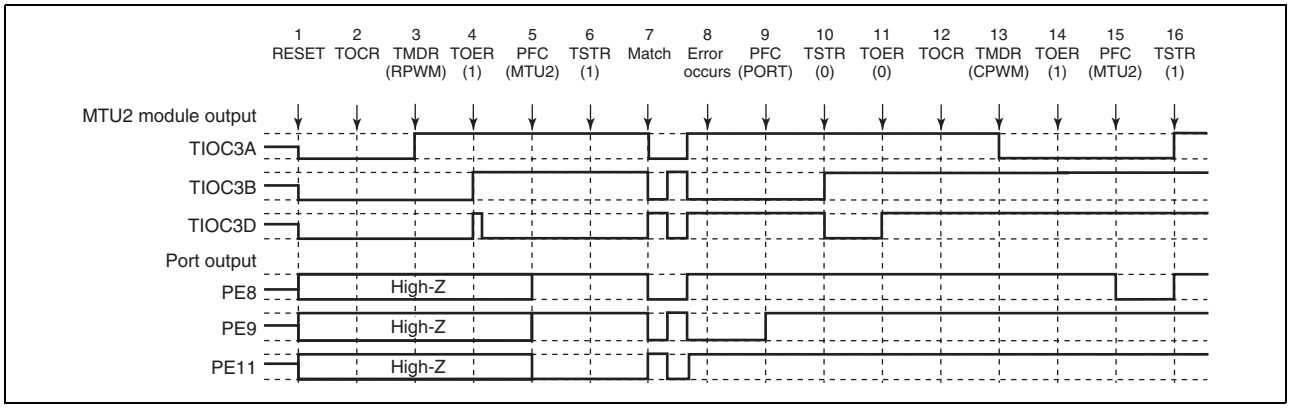

Figure 10.142 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Complementary PWM Mode

1 to 10 are the same as in Figure 10.140.

11. Disable channel 3 and 4 output with TOER.
12. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
13. Set complementary PWM. (The cyclic output pin of this module outputs a low-level signal.)
14. Enable channel 3 and 4 output with TOER.
15. Set the multi-function timer pulse unit 2 output with the general I/O port.
16. Operation is restarted by TSTR.

(29) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 10.143 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in reset-synchronized PWM mode after re-setting.

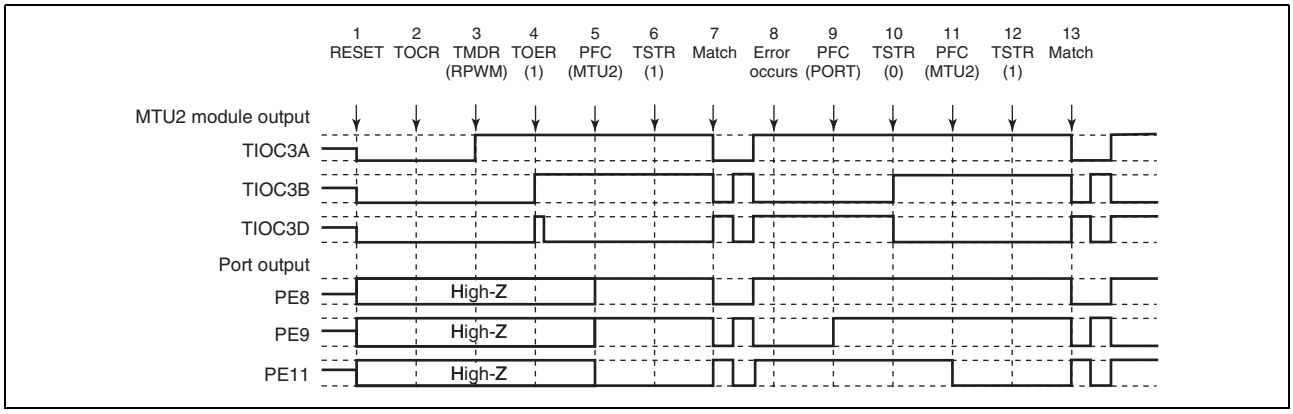

Figure 10.143 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Reset-Synchronized PWM Mode

1 to 10 are the same as in Figure 10.140.

11. Set the multi-function timer pulse unit 2 output with the general I/O port.
12. Operation is restarted by TSTR.
13. The reset-synchronized PWM waveform is output on compare-match occurrence.

11. OS Timer

11.1 Functional Overview

The OS timer has the following features.

- Two operating modes
  - Interval timer mode
  - Free-running comparison mode
- Choice between startup of DMA by compare match and generation of interrupt

11.1.1 Features of OSTM

Channels

This product has the following number of channels of the OS timer.

Table 11.1 Channels of OS timer

	OS Timer
Number of Channels	2
Name	OSTMn

Meaning of n

Throughout this section, the individual channels of the OS timer are identified by the index "n" (n = 0, 1), for example OSTMnTO for the OS timer n output register.

Register address

The register addresses of the OS timer are given as offsets from the individual base addresses <OSTMn_base>.

The register base addresses of each OSTMn are listed in the following table.

Table 11.2 Register Base Addresses

Base Address Name	Base Address
<OSTM0_base>	FCFE C000$_H$
<OSTM1_base>	FCFE C400$_H$

Interrupts

The OS timers can generate the following interrupt requests.

Table 11.3 OSTMn Interrupt Requests

OSTMn Signal	Function	Startup of Direct Memory Access Controller
OSTM0TINT	OSTM0 interrupt	√
OSTM1TINT	OSTM1 interrupt	√

11.2 Registers

The OS timer is controlled and operated by the following registers.

11.2.1 Registers Overview

The list of OSTMn (n = 0, 1) registers and the memory addresses are as follows.

For the base addresses, see the Table 11.2.

For the actual addresses, the offset values indicated in the following table are added to the base addresses.

Register Name	Function	R/W	Reset Value	Access Unit (bit)			Address
				8	16	32	
OSTMnCMP	OSTM compare register	R/W	0000 0000_H	—	—	√	<OSTMn_base> + 00_H
OSTMnCNT	OSTM counter register	R	FFFF $FFFF_H$	—	—	√	<OSTMn_base> + 04_H
OSTMnTE	OSTM count enable status register	R	00_H	√	—	—	<OSTMn_base> + 10_H
OSTMnTS	OSTM count start trigger register	W	00_H	√	—	—	<OSTMn_base> + 14_H
OSTMnTT	OSTM count stop trigger register	W	00_H	√	—	—	<OSTMn_base> + 18_H
OSTMnCTL	OSTM control register	R/W	00_H	√	—	—	<OSTMn_base> + 20_H

11.2.2 Details of OSTM Registers

11.2.2.1 OSTMnCMP — OSTM Compare Register

Depending on the mode of operation, this register holds the start value for the down-counter or the value for comparison with that of the counter.

Access: This register is readable/writable in 32-bit units.

Address: <OSTMn_base>

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSTMnCMP[31:16]															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OSTMnCMP[15:0]															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 11.4 OSTMnCMP register contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCMP [31:0]	• In interval timer mode: start value of the down-counter • In free-running comparison mode: value for comparison

11.2.2.2 OSTMnCNT — OSTM Counter Register

This register indicates the counter value of the timer.

Access: This register is readable in 32-bit units.

Address: OSTMn_base> + 4_H

Initial value: The initial value depends on the operating mode of the OS timer. Refer to Table 11.6, Correspondence between Operating Mode, Counting Direction and Initial Value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSTMnCNT[31:16]															
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 11.5 OSTMnCNT register contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCNT [31:0]	32-bit counter value

The following table shows the correspondence between operating mode, counting direction and initial value. The initial value is the value read from the counter after a change to the operating mode.

Table 11.6 Correspondence between Operating Mode, Counting Direction and Initial Value

Timer Operating Mode	OSTMnCTL.OSTMnMD1	Counting Direction	Initial value
Interval timer mode	0 *1	Down	FFFF FFFF$_H$
Free-running comparison mode	1	Up	0000 0000$_H$

Note 1. Value after reset

11.2.2.3 OSTMnTE — OSTM Count Enable Status Register

This register indicates whether the counter is enabled or disabled.

Access: This register is readable in 8-bit units.

Address: <OSTMn_base>+ 10_H

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	OSTMnTE
R/W	R	R	R	R	R	R	R	R

Table 11.7 OSTMnTE register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	Reserved These bits are always read as 0. The write value should always be 0.
0	OSTMnTE	This bit indicates whether the counter is enabled or disabled. 0: Counter disabled 1: Counter enabled This bit is set to 1 in response to OSTMnTS.OSTMnTS being set to 1. This bit is reset to 0 in response to OSTMnTT.OSTMnTT being set to 1.

NOTE

When OSTMnTE = 0, the counter retains its value.

If the counter is restarted, it

- restarts counting down from the value in the OSTMnCMP register if it is in interval timer mode or
- restarts counting up from the counter value 0000 0000_H if it is in free running comparison mode.

11.2.2.4 OSTMnTS — OSTM Count Start Trigger Register

This register starts the counter.

Access: This register is writable in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base>+ 14_H

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	OSTMnTS
R/W	R	R	R	R	R	R	R	W

Table 11.8 OSTMnTS register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	Reserved These bits are always read as 0. The write value should always be 0.
0	OSTMnTS	This bit starts the counter. 0: This setting has no effect. 1: Starts the counter and sets OSTMnTE.OSTMnTE = 1. • In interval timer mode, a forced restart is executed if this bit is set while OSTMnTE.OSTMnTE = 1. • In free-running comparison mode, setting this bit is ignored as long as OSTMnTE.OSTMnTE = 1.

11.2.2.5 OSTMnTT — OSTM Count Stop Trigger Register

This register stops the counter.

Access: This register is writable in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base>+ 18_H

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	OSTMnTT
R/W	R	R	R	R	R	R	R	W

Table 11.9 OSTMnTT register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	Reserved These bits are always read as 0. The write value should always be 0.
0	OSTMnTT	Stops the counter. 0: This setting has no effect. 1: Stops the counter and clears the OSTMnTE.OSTMnTE bit.

11.2.2.6 OSTMnCTL — OSTM Control Register

This register specifies the operating mode for the counter and controls enabling/disabling of OSTMnTINT interrupt requests when counting starts.

Access: This register is readable/writable in 8-bit units. Writing to this register is only possible if the counter is disabled (OSTMnTOE.OSTMnTOE = 0).

Address: <OSTMn_base>+ 20_H

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	OSTMnMD1	OSTMnMD0
R/W	R	R	R	R	R	R	R/W	R/W

Table 11.10 OSTMnCTL register contents

Bit Position	Bit Name	Function
7 to 2	Reserved	Reserved These bits are always read as 0. The write value should always be 0.
1	OSTMnMD1	Specifies the operating mode for the counter. 0: Interval timer mode 1: Free-running comparison mode
0	OSTMnMD0	Controls enabling/disabling of OSTMnTINT interrupt requests when counting starts. 0: Disables the interrupts when counting starts. 1: Enables the interrupts when counting starts.

11.3 Functional Description

Each OS timer is a 32-bit timer/counter.

The settings for operating mode specify the direction of counting (up or down) and the generation of interrupt requests.

11.3.1 Block Diagram

The following block diagram shows the main components of OSTM.

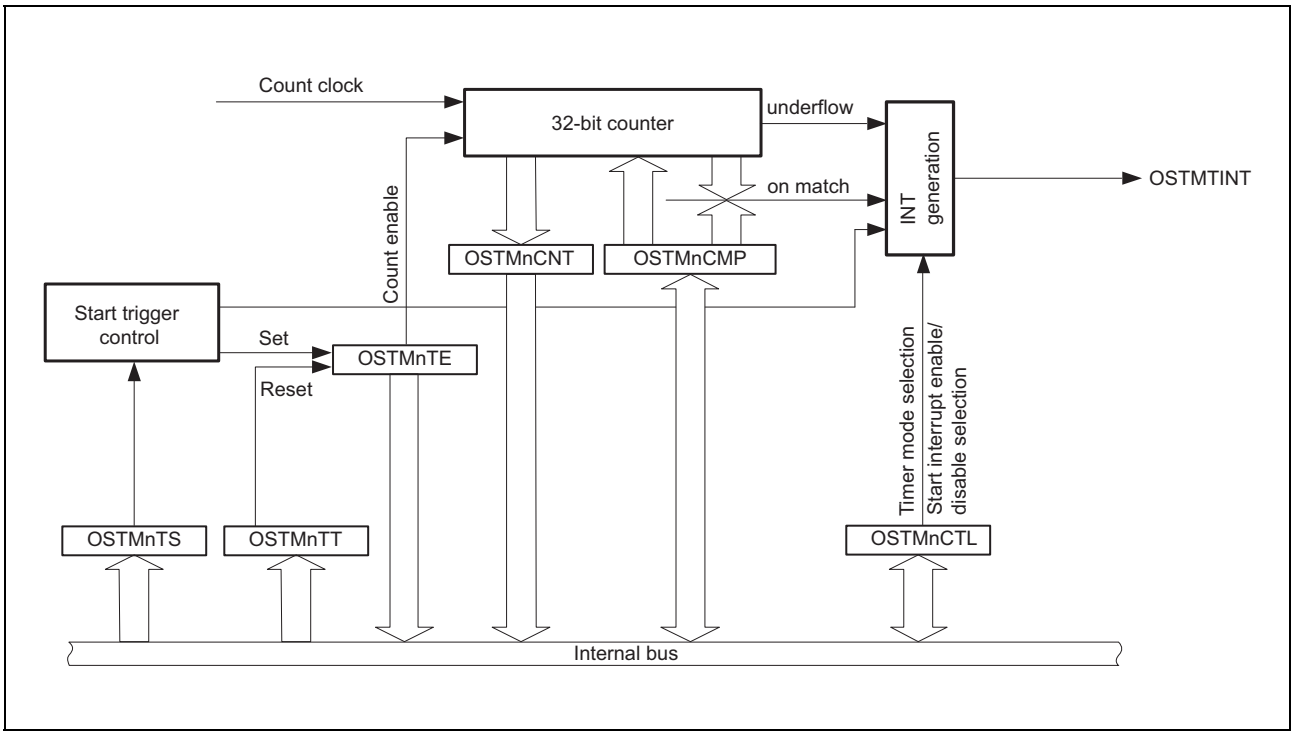

Figure 11.1 Block Diagram of OSTM

11.3.2 Count Clock

The count clock of OSTMn is P0ϕ.

11.3.3 Generation of Interrupt Request

An OSTMnTINT interrupt request is generated whenever the counter reaches 0000 0000_H (in interval timer mode) or matches the comparison value (in free-running comparison mode).

An interrupt request can also be generated on starting and restarting of the counter. This is controlled by the OSTMnCTL.OSTMnMD0 bit.

This operation is shown in the following figure.

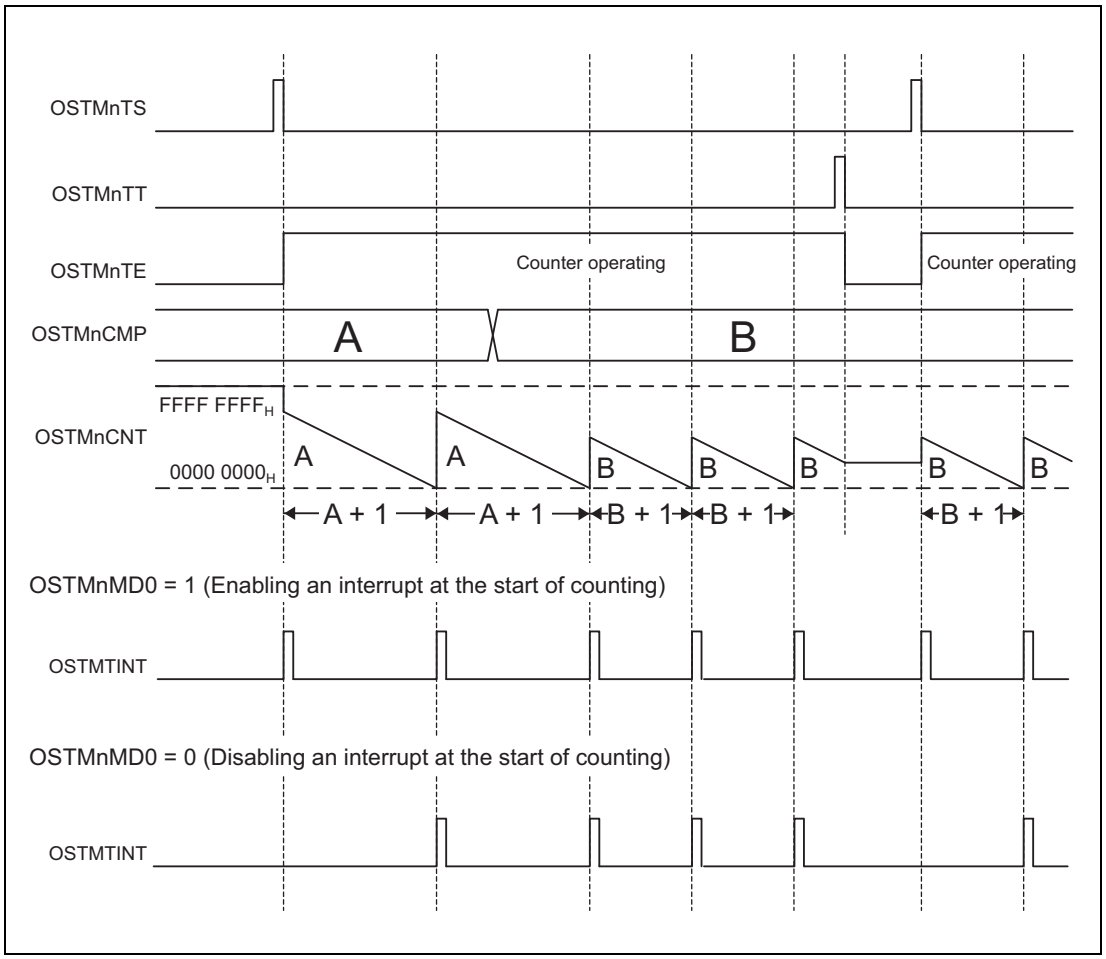

Figure 11.2 Generating an Interrupt when Counting Starts (in Interval Timer Mode)

11.3.4 Starting and Stopping the Timer

The OS timer is started and stopped as follows.

Starting the timer

The timer is started in either of the following way:

- setting the OSTMnTS.OSTMnTSF bit to 1

Status bit OSTMnTE.OSTMnTE is set to 1.

The counter starts to count up or down in accord with the settings for operating mode.

Stopping the timer

Setting the OSTMnTT.OSTMnTT bit to 1 stops the timer.

This also clears the OSTMnTE.OSTMnTE status flag.

11.3.5 Interval Timer Mode

Select the interval timer mode when an OS timer is to be used as a reference timer for generating interrupt requests at a fixed interval.

11.3.5.1 Basic Operation in Interval Timer Mode

In interval timer mode, the timer counts down from the value specified in the OSTMnCMP register. An OSTMnTINT interrupt request is generated when the counter reaches 0000 0000_H.

Select interval timer mode by setting OSTMnCTL.OSTMnMD1 = 0.

New values can be written to the OSTMnCMP register at any time. If it is rewritten during count operation, the counter loads the new OSTMnCMP value when the next 0000 0000_H is reached.

Cycles of OSTMnTINT output

The cycle of OSTMnTINT output is as follows.

- OSTMnTINT generation cycle = counter-clock cycle × (OSTMnCMP + 1)

The following figure shows the basic operation of OSTM when counter-start interrupts is enabled in interval timer mode.

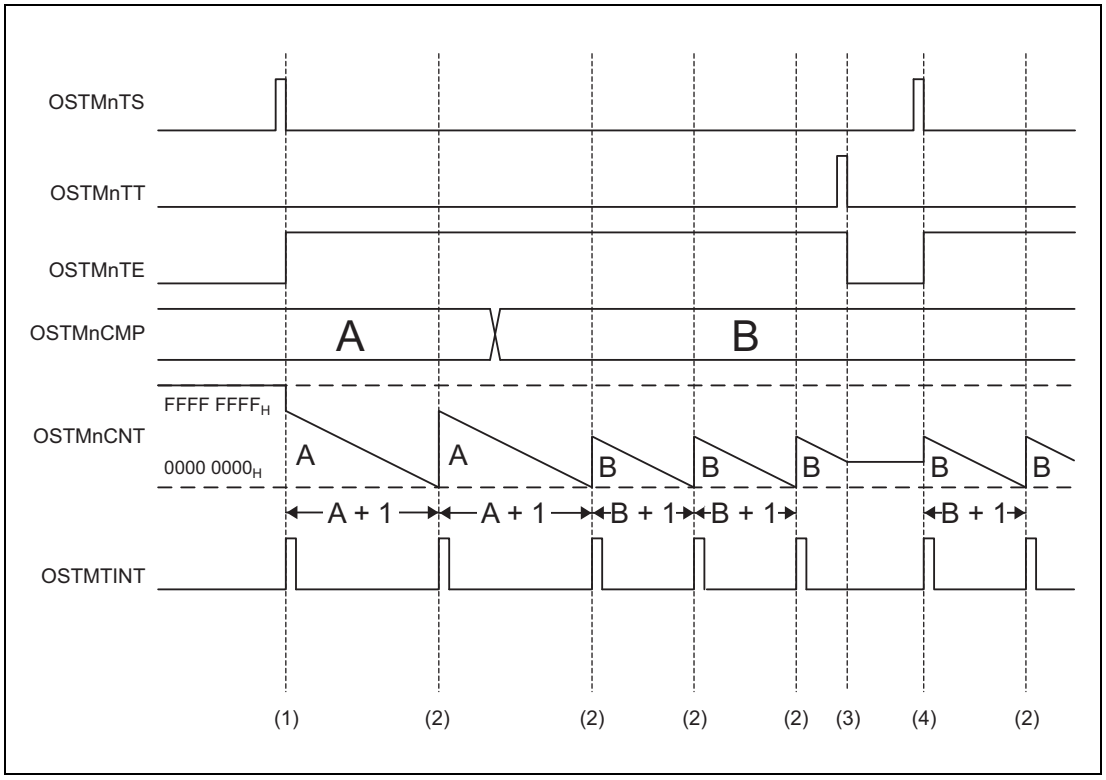

Figure 11.3 Timing Diagram of OSTM in Interval Timer Mode

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter.
The counter starts counting down from the value of OSTMnCMP.
If OSTMnCTL.OSTMnMD0 is 1, OSTMTINT interrupt requests are generated at the start of counting. The OSTMnCNT register contains the current value as the counter.

(2) When the counter reaches 0000 0000$_H$, an OSTMTINT interrupt request is generated. The counter loads the new start value from OSTMnCMP and continues counting down.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.

(4) When counting is restarted (OSTMnTS.OSTMnTS = 1), the counter loads the new start value from OSTMnCMP and starts counting down.

Forced restart

The counter is forcibly restarted by setting OSTMnTS.OSTMnTS = 1 during counting.

The counter loads the start value from the OSTMnCMP register and continues to count down.

The following figure shows the forced restart of the OS Timer in interval timer mode, with counter-start interrupts enabled (OSTMnCTL.OSTMnMD0 = 1).

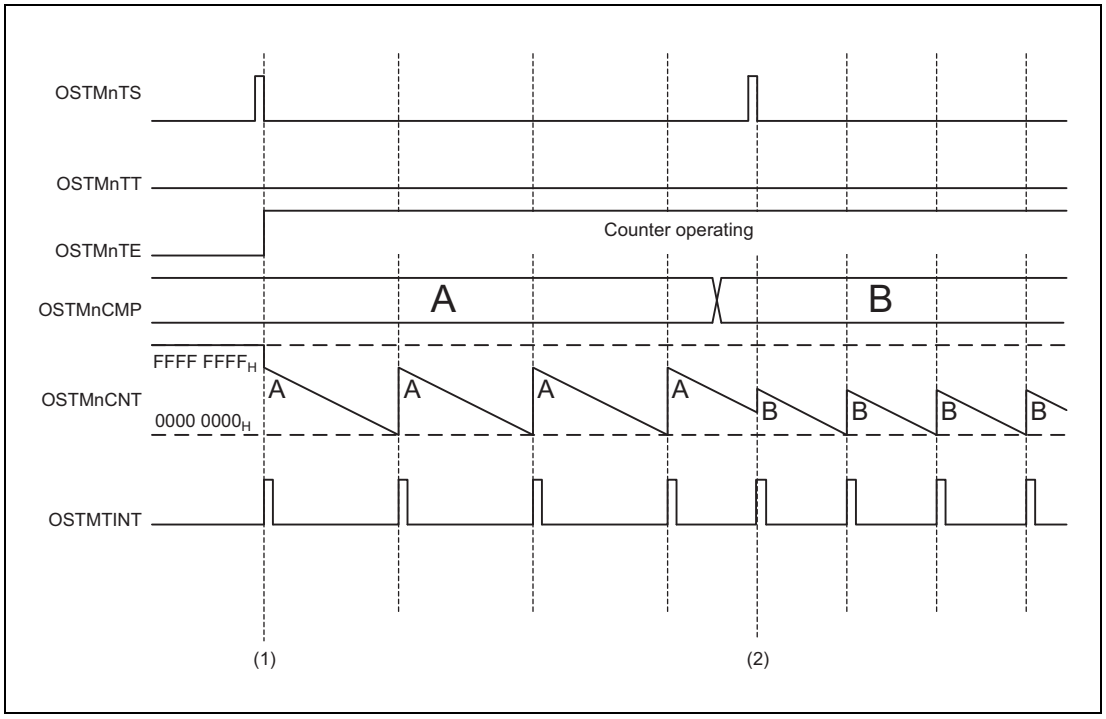

Figure 11.4 Timing Diagram of Forced Restart in Interval Timer Mode

Operations shown in the above timing diagram are as follows.

(1) The counter is started and stopped as described under Figure 11.3, Timing Diagram of OSTM in Interval Timer Mode.

(2) Setting OSTMnTS.OSTMnTS = 1 restarts the counter while counting is in progress (i.e. while OSTMnTE.OSTMnTE = 1).
The counter immediately restarts counting down, starting with the current value of OSTMnCMP.
When OSTMnCTL.OSTMnMD0 = 1, an OSTMTINT interrupt request is generated when counting starts.

11.3.5.2 Operation when OSTMnCMP = 0000 0000$_H$

When OSTMnCMP = 0000 0000$_H$, OSTM behaves as follows.

- When the counter is enabled, the OSTMTINT interrupt request is always set to 1.

The following figure shows operations of OSTM when OSTMnCMP = 0000 0000$_H$, and counter-start interrupts are enabled.

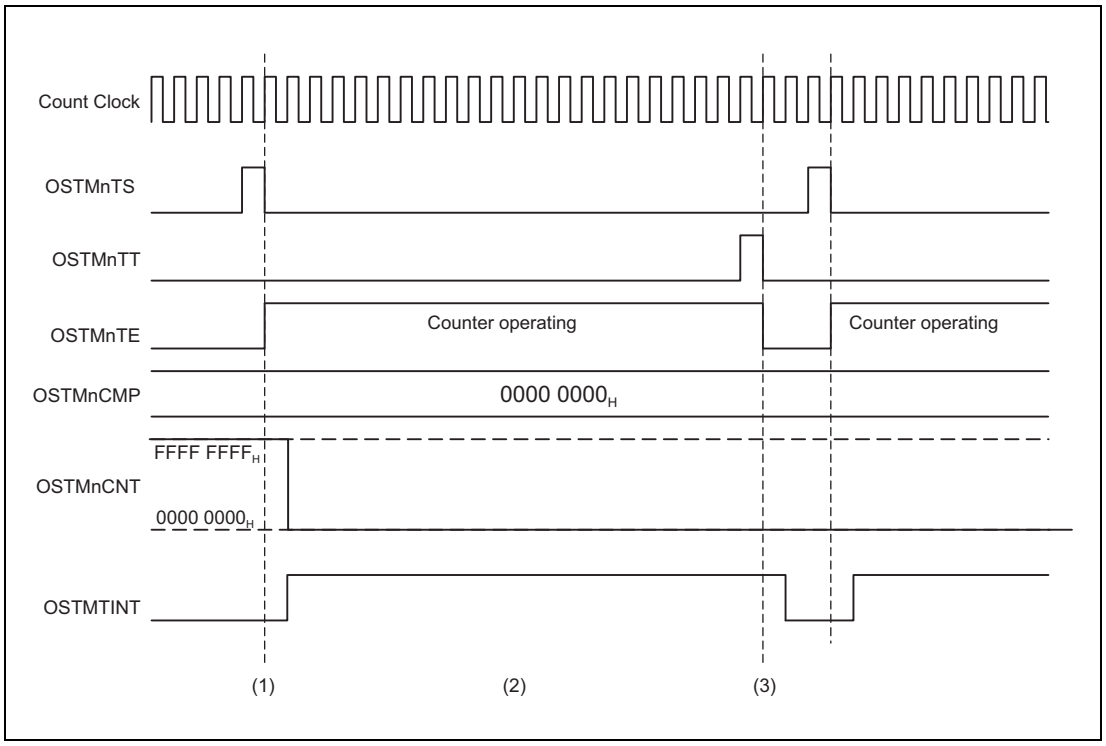

Figure 11.5 Timing Diagram when OSTMnCMP = 0000 0000$_H$ in Interval Timer Mode

The timing diagram above shows the following operations:

(1) The counter is reloaded with the value in OSTMnCMP as soon as it starts counting, so the value 0000 0000$_H$ is retained in OSTMnCMP.

(2) The OSTMTINT interrupt request is continuously asserted.

(3) After the counter stops, the OSTMTINT interrupt request signal is deasserted.

(4) When interrupts on starting of the counter are disabled, no interrupt is generated when counting starts.

11.3.6 Free-Running Comparison Mode

11.3.6.1 Basic Operation in Free-Running Comparison Mode

In free-running comparison mode, the counter counts up from 0000 0000$_H$ to FFFF FFFF$_H$. An OSTMnTINT interrupt request is output when the current value of the counter matches the value of the OSTMnCMP register. The free-running comparison mode is selected by setting the OSTMnCTL.OSTMnMD1 bit to 1.

New values can be written to the OSTMnCMP register at any time.

The following figure shows the basic operation of OSTM in free-run compare mode with the start of counting enabled (OSTMnCTL.OSTMnMD0 = 1).

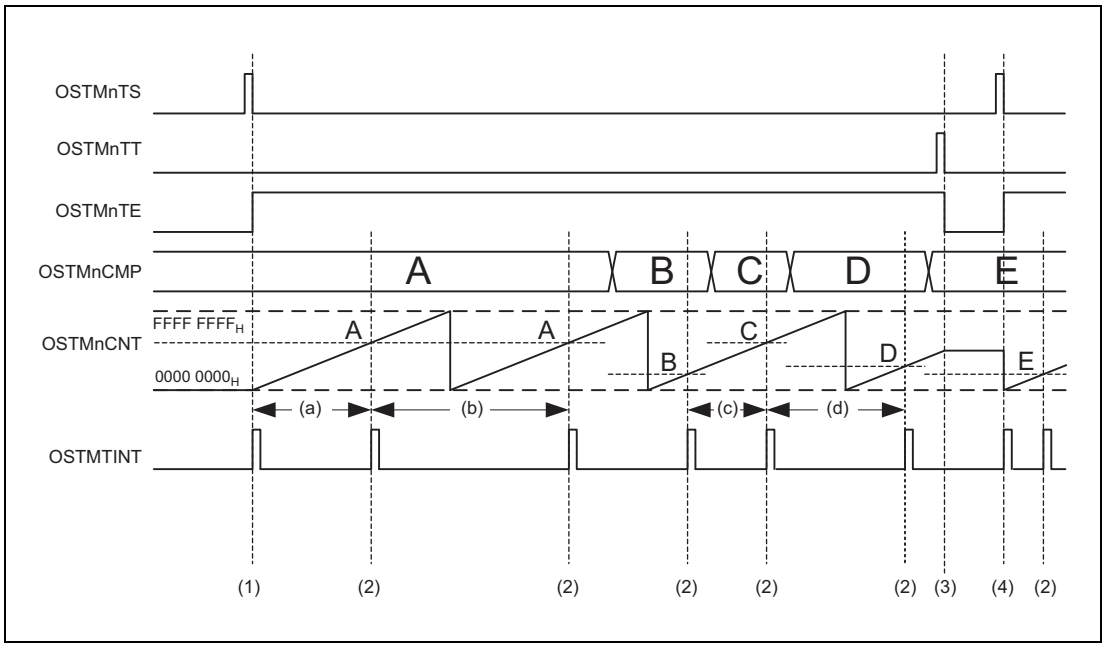

Figure 11.6 Timing Diagram of OSTM in Free-Run Compare Mode

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1.
The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter counts up from 0000 0000$_H$ to FFFF FFFF$_H$. The OSTMnCNT register is the counter, so it contains the current value.
When OSTMnCTL.OSTMnMD0 = 1, an OSTMTINT interrupt request is generated at the start of counting.

(2) When the current counter value matches the value in the OSTMnCMP register, an OSTMTINT interrupt request is generated.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter.
The counter retains its current value until it is restarted.

(4) Counting by the counter restarts from 0000 0000$_H$ when OSTMnTS.OSTMnTS = 1.

OSTMTINT period

The OSTMTINT generation period is different at the start of counting and depends on the old and new compare values if OSTMnCMP is rewritten during operation.

Table 11.11 OSTMTINT Generation Timing

Old Value for Comparison	New Value for Comparison	Counter Value at Time of Rewriting	Period of OSTMTINT Generation	Label in Timing Diagram
Counter starts			(A + 1) × counter clock period	(a)
A	A	No rewriting	(FFFF FFFF$_H$ + 1) × counter clock period	(b)
B	C > B	B < counter value < C	(C – B) × counter clock period	(c)
C	D < C	Counter value > D,C	(FFFF FFFF$_H$ – C + D + 1) × counter clock period	(d)

Forced restart

Forced restarting does not proceed during counting even if the OSTMnTS.OSTMnTS bit is set.

The counter ignores the attempted setting and continues counting.

11.3.6.2 Operation when OSTMnCMP = 0000 0000$_H$

The following figure shows the operation of OSTM when OSTMnCMP = 0000 0000$_H$, and counter-start interrupts are enabled (OSTMnCTL.OSTMnMD0 = 1).

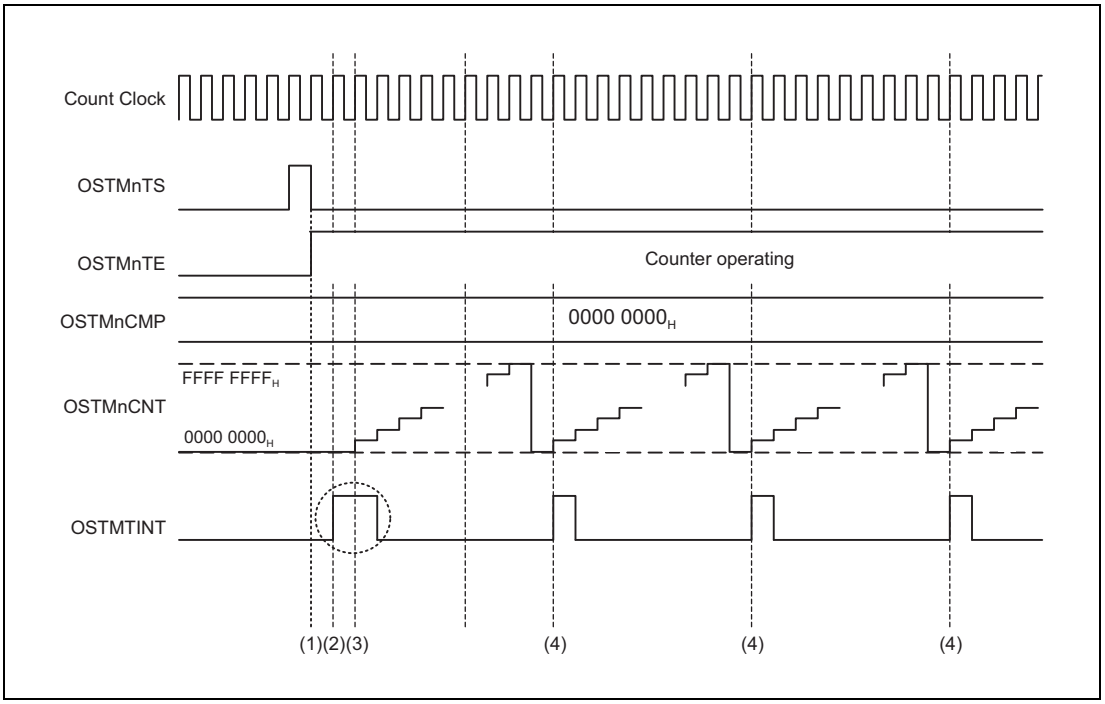

Figure 11.7 Timing Diagram when OSTMnCMP = 0000 0000$_H$ in Free-Run Compare Mode

The timing diagram above shows the following operations.

(1) Once the counter starts, it counts up from 0000 0000$_H$ to FFFF FFFF$_H$.

(2) An OSTMTINT interrupt request is generated when counting starts.

(3) If the current counter value matches OSTMnCMP, an OSTMTINT interrupt request is generated. If OSTMnCMP = 0000 0000$_H$ in the above case, OSTMTINT is generated over two clock cycles.

(4) Every (FFFF $FFFF_H$ + 1) clock cycles the OSTMTINT interrupt request is asserted.

When interrupts on starting of the counter are disabled, no interrupt is generated when counting starts.

12. Watchdog Timer

This LSI includes the watchdog timer, which externally outputs an overflow signal ($\overline{\text{WDTOVF}}$) on overflow of the counter when the value of the counter has not been updated because of a system malfunction. This module can simultaneously generate an internal reset signal for the entire LSI.
This module is a single channel timer that counts up the clock oscillation settling period when the system leaves software standby mode. It can also be used as a general watchdog timer or interval timer.

12.1 Features

- Can be used to ensure the clock oscillation settling time
  This module is used in leaving software standby mode.
- Can switch between watchdog timer mode and interval timer mode.
- Outputs $\overline{\text{WDTOVF}}$ signal in watchdog timer mode
  When the counter overflows in watchdog timer mode, the $\overline{\text{WDTOVF}}$ signal is output externally. It is possible to select whether to reset the LSI internally when this happens. The internal reset signal is used as the power-on reset signal.
- Interrupt generation in interval timer mode
  An interval timer interrupt is generated when the counter overflows.
- Choice of eight counter input clocks
  Eight clocks (P0ϕ × 1 to P0ϕ × 1/16384) that are obtained by dividing the peripheral clock can be selected.

Figure 12.1 shows a block diagram.

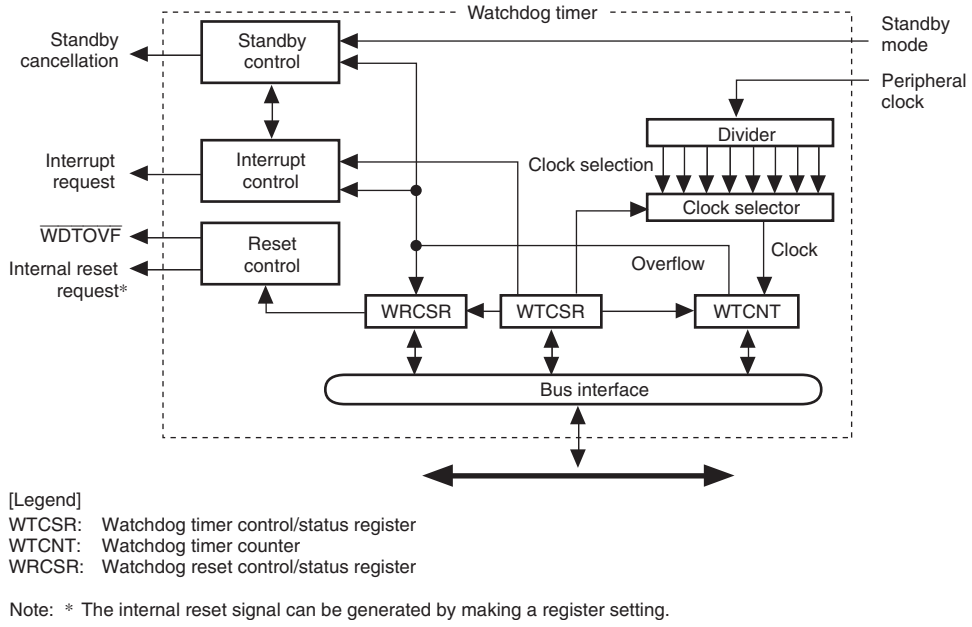

Figure 12.1 Block Diagram

12.2 Input/Output Pin

Table 12.1 shows the pin configuration.

Table 12.1 Pin Configuration

Pin Name	Symbol	I/O	Function
Watchdog timer overflow	$\overline{\text{WDTOVF}}$	Output	Outputs the counter overflow signal in watchdog timer mode

12.3 Register Descriptions

Table 12.2 shows the register configuration.

Table 12.2 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Watchdog timer counter	WTCNT	R/W	H'00	H'FCFE0002	16*
Watchdog timer control/status register	WTCSR	R/W	H'18	H'FCFE0000	16*
Watchdog reset control/status register	WRCSR	R/W	H'1F	H'FCFE0004	16*

Note: * For the access size, see section 12.3.4, Notes on Register Access.

12.3.1 Watchdog Timer Counter (WTCNT)

WTCNT is an 8-bit readable/writable register that is incremented by cycles of the selected clock signal. When an overflow occurs, it generates a watchdog timer overflow signal ($\overline{\text{WDTOVF}}$) in watchdog timer mode and an interrupt in interval timer mode.

Use 16-bit access to write to WTCNT, writing H'5A in the upper byte. Use 8-bit access to read from WTCNT.

Note: The method for writing to WTCNT differs from that for other registers to prevent erroneous writes. See section 12.3.4, Notes on Register Access for details.

Bit:	7	6	5	4	3	2	1	0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

12.3.2 Watchdog Timer Control/Status Register (WTCSR)

WTCSR is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flags, and timer enable bit.

When used to count the clock oscillation settling time for canceling software standby mode, it retains its value after counter overflow.

Use 16-bit access to write to WTCSR, writing H'A5 in the upper byte. Use 8-bit access to read from WTCSR.

Note: The method for writing to WTCSR differs from that for other registers to prevent erroneous writes. See section 12.3.4, Notes on Register Access for details.

Bit:	7	6	5	4	3	2	1	0
	IOVF	WT/$\overline{\text{IT}}$	TME	-	-	CKS[2:0]		
Initial value:	0	0	0	1	1	0	0	0
R/W:	R/(W)	R/W	R/W	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IOVF	0	R/(W)	Interval Timer Overflow Indicates that WTCNT has overflowed in interval timer mode. This flag is not set in watchdog timer mode. 0: No overflow 1: WTCNT overflow in interval timer mode [Clearing condition] • When 0 is written to IOVF after reading IOVF
6	WT/$\overline{\text{IT}}$	0	R/W	Timer Mode Select Selects whether to use this module as a watchdog timer or an interval timer. 0: Use as interval timer 1: Use as watchdog timer Note: When the WTCNT overflows in watchdog timer mode, the $\overline{\text{WDTOVF}}$ signal is output externally. If this bit is modified when this module is running, the up-count may not be performed correctly.

Bit	Bit Name	Initial Value	R/W	Description
5	TME	0	R/W	Timer Enable Starts and stops timer operation. Clear this bit to 0 when using this module in software standby mode or when changing the clock frequency. 0: Timer disabled Count-up stops and WTCNT value is retained 1: Timer enabled
4,3	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
2 to 0	CKS[2:0]	000	R/W	Clock Select These bits select the clock to be used for the WTCNT count from the eight types obtainable by dividing the peripheral clock (P0ϕ). The overflow period that is shown inside the parenthesis in the table is the value when the peripheral clock (P0ϕ) is 33.33 MHz.

Bits 2 to 0	Clock Ratio	Overflow Cycle
000:	1 x P0ϕ	7.7 µs
001:	1/64 x P0ϕ	490 µs
010:	1/128 x P0ϕ	979 µs
011:	1/256 x P0ϕ	2.0 ms
100:	1/512 x P0ϕ	3.9 ms
101:	1/1024 x P0ϕ	7.8 ms
110:	1/4096 x P0ϕ	31 ms
111:	1/16384 x P0ϕ	125 ms

Note: If bits CKS[2:0] are modified when this module is running, the up-count may not be performed correctly. Ensure that these bits are modified only when this module is not running.

12.3.3 Watchdog Reset Control/Status Register (WRCSR)

WRCSR is an 8-bit readable/writable register that controls output of the internal reset signal generated by watchdog timer counter (WTCNT) overflow.

Note: The method for writing to WRCSR differs from that for other registers to prevent erroneous writes. See section 12.3.4, Notes on Register Access for details.

Bit:	7	6	5	4	3	2	1	0
	WOVF	RSTE	-	-	-	-	-	-
Initial value:	0	0	0	1	1	1	1	1
R/W:	R/(W)	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	WOVF	0	R/(W)	Watchdog Timer Overflow Indicates that the WTCNT has overflowed in watchdog timer mode. This bit is not set in interval timer mode. 0: No overflow 1: WTCNT has overflowed in watchdog timer mode [Clearing condition] • When 0 is written to WOVF after reading WOVF
6	RSTE	0	R/W	Reset Enable Selects whether to generate a signal to reset the LSI internally if WTCNT overflows in watchdog timer mode. In interval timer mode, this setting is ignored. 0: Not reset when WTCNT overflows* 1: Reset when WTCNT overflows Note: * LSI not reset internally, but WTCNT and WTCSR reset within this module.
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
4 to 0	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.

12.3.4 Notes on Register Access

The watchdog timer counter (WTCNT), watchdog timer control/status register (WTCSR), and watchdog reset control/status register (WRCSR) are more difficult to write to than other registers. The procedures for reading or writing to these registers are given below.

(1) Writing to WTCNT and WTCSR

These registers must be written by a 16-bit transfer instruction. They cannot be written by an 8- or 32-bit transfer instruction.

When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in Figure 12.2. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

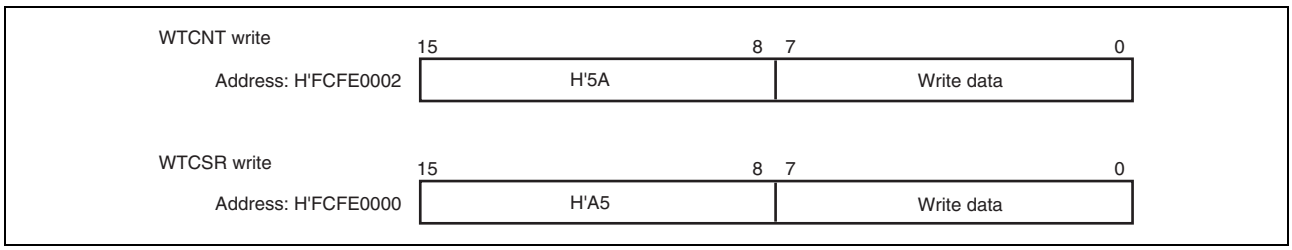

Figure 12.2 Writing to WTCNT and WTCSR

(2) Writing to WRCSR

WRCSR must be written by a 16-bit access to address H'FCFE0004. It cannot be written by 8- or 32-bit transfer instructions.

Procedures for writing 0 to WOVF (bit 7) and for writing to RSTE (bit 6) are different, as shown in Figure 12.3.

To write 0 to the WOVF bit, the write data must be H'A5 in the upper byte and H'00 in the lower byte. This clears the WOVF bit to 0. The RSTE bit is not affected. To write to the RSTE bit, the upper byte must be H'5A and the lower byte must be the write data. The value of bit 6 of the lower byte is transferred to the RSTE bit. The WOVF bit is not affected.

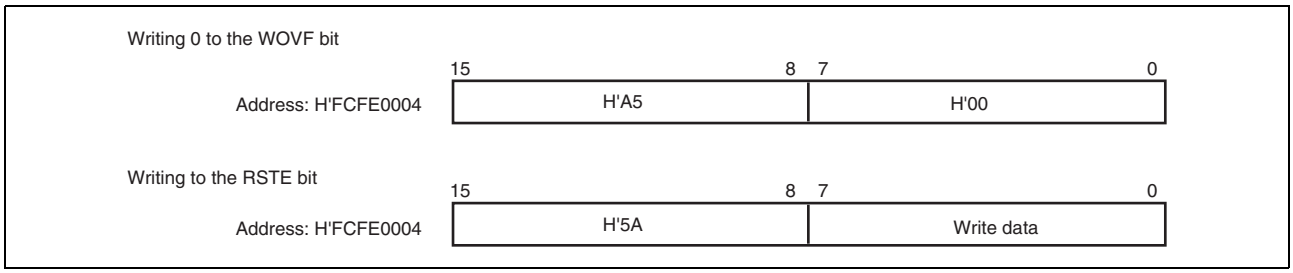

Figure 12.3 Writing to WRCSR

(3) Reading from WTCNT, WTCSR, and WRCSR

WTCNT, WTCSR, and WRCSR are read in a method similar to other registers. WTCSR is allocated to address H'FCFE0000, WTCNT to address H'FCFE0002, and WRCSR to address H'FCFE0004. Eight-bit transfer instructions must be used for reading from these registers.

12.4 Usage

12.4.1 Canceling Software Standby Mode

This module can be used to cancel software standby mode with an interrupt such as an NMI interrupt. The procedure is described below. (This module does not operate when resets are used for canceling, so keep the $\overline{\text{RES}}$ pin low until clock oscillation settles.)

1. Before making a transition to software standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS[2:0] bits in WTCSR and the initial value of the counter in WTCNT. These values should ensure that the time till count overflow is equal to or longer than the clock oscillation settling time.
3. After setting the STBY and DEEP bits of the standby control register 1 (STBCR1: see section 42, Power-Down Modes) to 1 and 0 respectively, the execution of a WFI instruction puts the system in software standby mode and clock operation then stops.
4. This module starts counting by detecting the edge change of the NMI signal.
5. When the module count overflows, the clock pulse generator starts supplying the clock and this LSI resumes operation. The WOVF flag in WRCSR is not set when this happens.

12.4.2 Using Watchdog Timer Mode

1. Set the WT/$\overline{\text{IT}}$ bit in WTCSR to 1, the type of count clock in the CKS[2:0] bits in WTCSR, whether this LSI is to be reset internally or not in the RSTE bit in WRCSR, and the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
3. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
4. When the counter overflows, this module sets the WOVF flag in WRCSR to 1, and the $\overline{\text{WDTOVF}}$ signal is output externally (Figure 12.4). The $\overline{\text{WDTOVF}}$ signal can be used to reset the system. The $\overline{\text{WDTOVF}}$ signal is output for $64 \times$ P0ϕ clock cycles.
5. If the RSTE bit in WRCSR is set to 1, a signal to reset the inside of this LSI can be generated simultaneously with the $\overline{\text{WDTOVF}}$ signal. The internal reset signal is output for $128 \times$ P0ϕ clock cycles.
6. When an overflow reset of this module is generated simultaneously with a reset input on the $\overline{\text{RES}}$ pin, the $\overline{\text{RES}}$ pin reset takes priority, and the WOVF bit in WRCSR is cleared to 0.

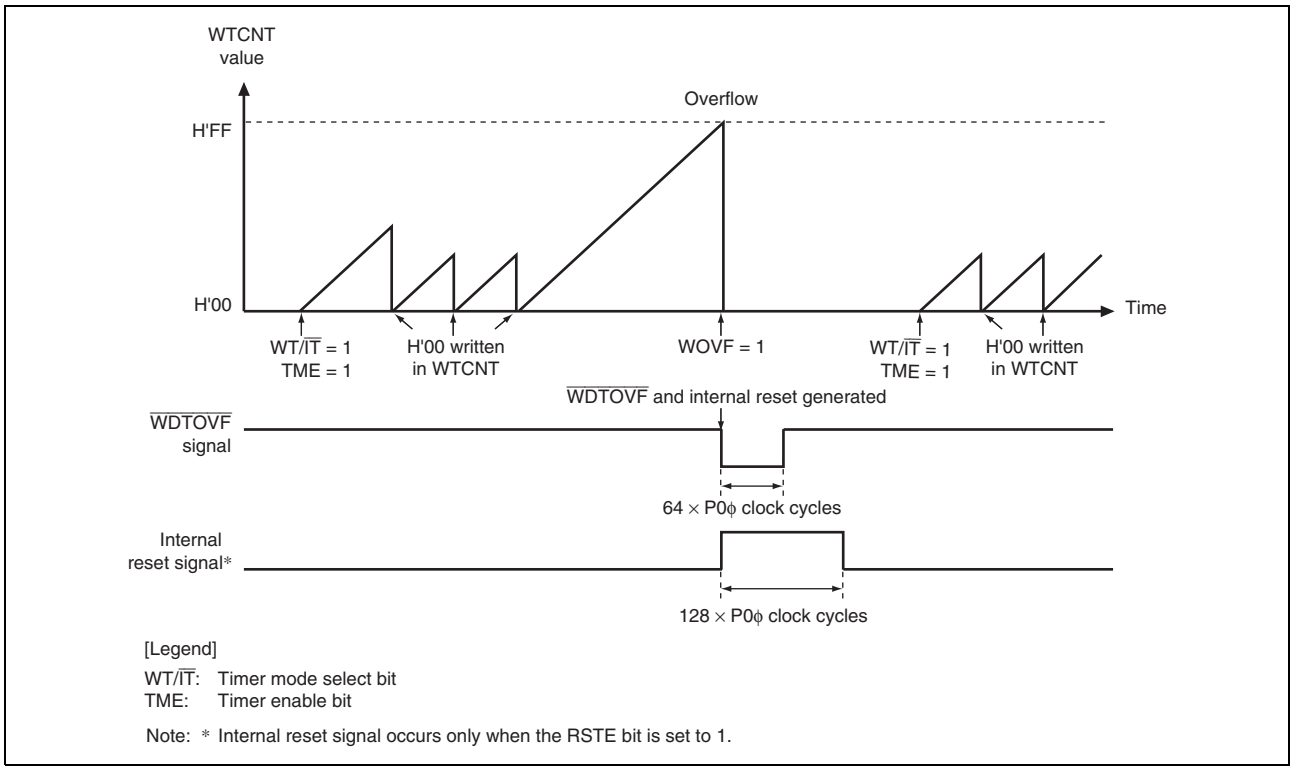

Figure 12.4 Operation in Watchdog Timer Mode

12.4.3 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

1. Clear the WT/$\overline{IT}$ bit in WTCSR to 0, set the type of count clock in the CKS[2:0] bits in WTCSR, and set the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
3. When the counter overflows, this module sets the IOVF bit in WTCSR to 1 and an interval timer interrupt request is sent to the interrupt controller. The counter then resumes counting.

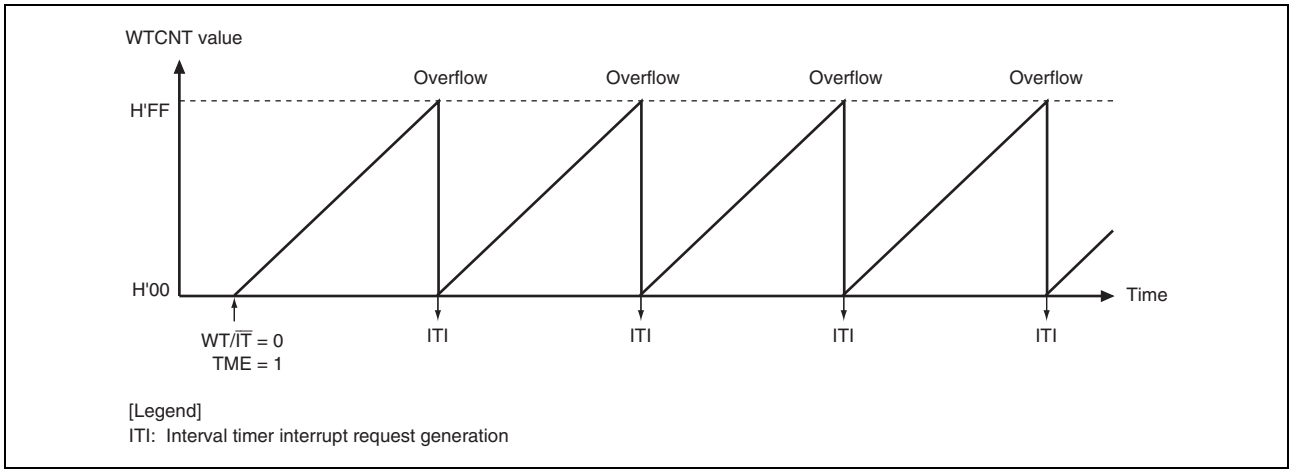

Figure 12.5 Operation in Interval Timer Mode

12.5 Usage Notes

Pay attention to the following points when using this module in either the interval timer or watchdog timer mode.

12.5.1 Timer Variation

After timer operation has started, the period from the power-on reset point to the first count up timing of WTCNT varies depending on the time period that is set by the TME bit of WTCSR. The shortest such time period is thus one cycle of the peripheral clock, P0ϕ, while the longest is the result of frequency division according to the value in the CKS[2:0] bits. The timing of subsequent incrementation is in accord with the selected frequency division ratio. Accordingly, this time difference is referred to as timer variation.

This also applies to the timing of the first incrementation after WTCNT has been written to during timer operation.

12.5.2 Prohibition against Setting H'FF to WTCNT

When the value in WTCNT reaches H'FF, this module assumes that an overflow has occurred. Accordingly, when H'FF is set in WTCNT, an interval timer interrupt or reset will occur immediately, regardless of the current clock selection by the CKS[2:0] bits.

12.5.3 Interval Timer Overflow Flag

When the value in WTCNT is H'FF, the IOVF flag in WTCSR cannot be cleared.

Only clear the IOVF flag when the value in WTCNT has either become H'00 or been changed to a value other than H'FF.

12.5.4 System Reset by $\overline{\text{WDTOVF}}$ Signal

If the $\overline{\text{WDTOVF}}$ signal is input to the $\overline{\text{RES}}$ pin of this LSI, this LSI cannot be initialized correctly.

Avoid input of the $\overline{\text{WDTOVF}}$ signal to the $\overline{\text{RES}}$ pin of this LSI through glue logic circuits. To reset the entire system with the $\overline{\text{WDTOVF}}$ signal, use the circuit shown in Figure 12.6.

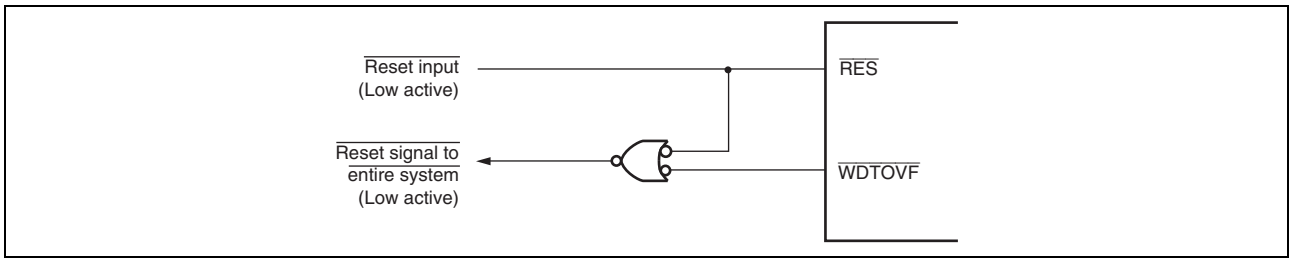

Figure 12.6 Example of System Reset Circuit Using $\overline{\text{WDTOVF}}$ Signal

12.5.5 Internal Reset in Watchdog Timer Mode

When an internal reset is generated due to an overflow of the watchdog timer counter (WTCNT) in watchdog timer mode, the watchdog reset control/status register (WRCSR) is not initialized, so the WOVF bit retains the value 1. As long as the WOVF bit is 1, an internal reset will not be generated even if the WTCNT overflows again.

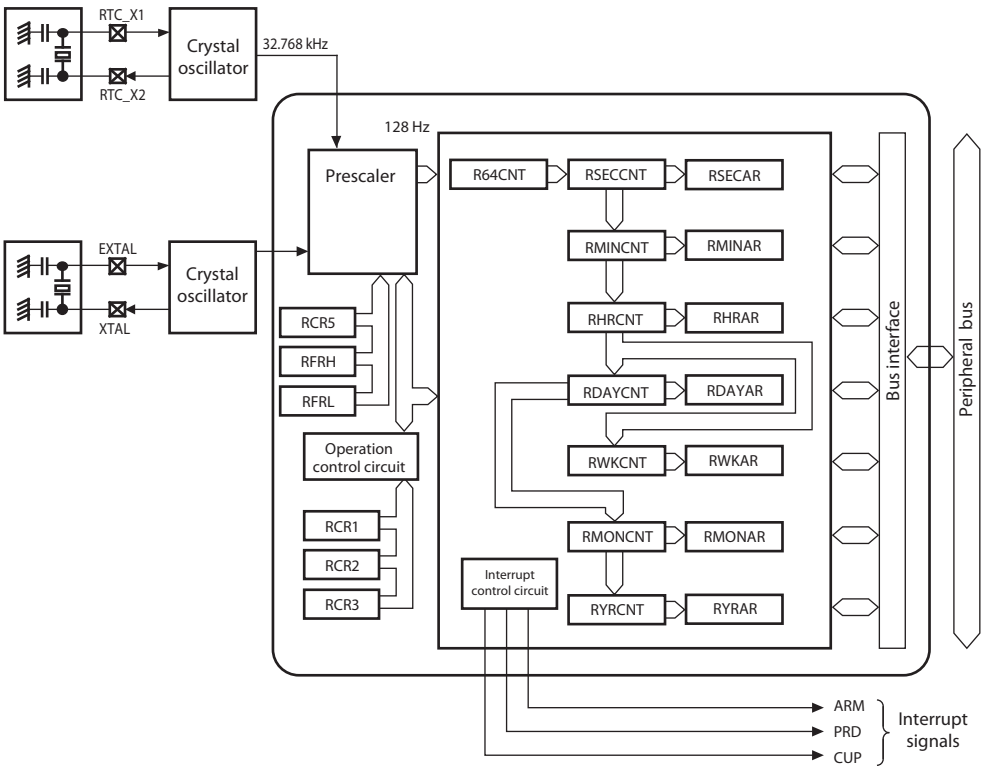
13. Realtime Clock

This LSI has a realtime clock and a 32.768-kHz crystal oscillator.

13.1 Features

- Clock and calendar functions (BCD format): Seconds, minutes, hours, day of the week, day, month, and year.
- 1-Hz to 64-Hz timer (binary format)
  64-Hz counter indicates the state of the divider circuit between 64 Hz and 1 Hz
- Start/stop function
- 30-second adjust function
- Alarm interrupt: Comparison with seconds, minutes, hours, day of the week, day, month, or year can be selected as a condition for the alarm interrupt
- Periodic interrupt: the interrupt cycle may be 1/64 second, 1/16 second, 1/4 second, 1/2 second, 1 second, or 2 seconds
- Carry interrupt: a carry interrupt indicates that a second counter carry is generated or a 64-Hz counter carry is generated reading the 64-Hz counter
- Automatic leap year adjustment
- The external clock signal input for internal operation or the external clock signal input dedicated to the clock operation can be selected as the operating clock signal for the clock function.
- Recovery from deep standby mode can be performed by an alarm interrupt.

Figure 13.1 shows the block diagram.



[Legend]

RSECCNT:	Second counter	RSECAR:	Second alarm register
RMINCNT:	Minute counter	RMINAR:	Minute alarm register
RHRCNT:	Hour counter	RHRAR:	Hour alarm register

13.2 Input/Output Pin

Table 13.1 shows the pin configuration.

Table 13.1 Pin Configuration

Pin Name	Symbol	I/O	Description
Realtime clock crystal resonator pin/external clock	RTC_X1	Input	Connects a 32.768-kHz crystal resonator for this module. External clock can be input to the RTC_X1 pin.
	RTC_X2	Output	
Internal clock crystal resonator/external clock	EXTAL	Input	Connects crystal resonator used for internal operation. For details, see section 6, Clock Pulse Generator.
	XTAL	Output	

13.3 Register Descriptions

Table 13.2 shows the register configuration.

Table 13.2 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
64-Hz counter	R64CNT	R	H'xx	H'FCFF1000	8
Second counter	RSECCNT	R/W	H'xx	H'FCFF1002	8

13.3.1 64-Hz Counter (R64CNT)

R64CNT indicates the state of the divider circuit between 64 Hz and 1 Hz.

Reading this register, when carry from 128-Hz divider stage is generated, sets the CF bit in the control register 1 (RCR1) to 1, which indicates that the carrying and reading the 64-Hz counter are performed at the same time. In this case, the R64CNT should be read again after writing 0 to the CF bit in RCR1 since the read value is not valid.

Setting the RESET or ADJ bit in the control register 2 (RCR2) to 1 initializes the divider circuit and the R64CNT.

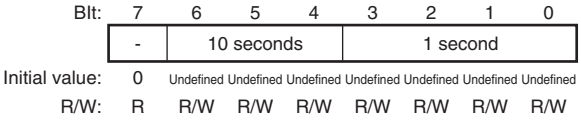
Bit:	7	6	5	4	3	2	1	0
	-	1Hz	2Hz	4Hz	8Hz	16Hz	32Hz	64Hz
Initial value:	0	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	1 Hz	Undefined	R	Indicate the state of the divider circuit between 64 Hz and 1 Hz.
5	2 Hz	Undefined	R	
4	4 Hz	Undefined	R	
3	8 Hz	Undefined	R	
2	16 Hz	Undefined	R	
1	32 Hz	Undefined	R	
0	64 Hz	Undefined	R	

13.3.2 Second Counter (RSECCNT)

RSECCNT is the counter used for setting/counting the BCD-coded second value. The count operation is performed by a carry for each second of the 64-Hz counter.

The assignable range is from 00 through 59 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

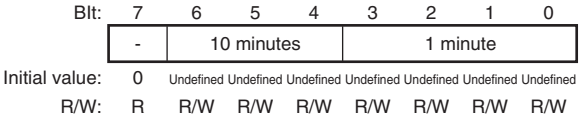


Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	10 seconds	Undefined	R/W	Counting Ten's Position of Seconds Counts from 0 to 5 for 60-seconds counting.
3 to 0	1 second	Undefined	R/W	Counting One's Position of Seconds Counts from 0 to 9, one number per second. When a carry is generated, 1 is added to the ten's position.

13.3.3 Minute Counter (RMINCNT)

RMINCNT is the counter used for setting/counting the BCD-coded minute value. The count operation is performed by a carry for each minute of the second counter.

The assignable range is from 00 through 59 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.



Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0.The write value should always be 0.
6 to 4	10 minutes	Undefined	R/W	Counting Ten's Position of Minutes Counts from 0 to 5 for 60-minutes counting.
3 to 0	1 minute	Undefined	R/W	Counting One's Position of Minutes Counts from 0 to 9, one number per minute. When a carry is generated, 1 is added to the ten's position.

13.3.4 Hour Counter (RHRCNT)

RHRCNT is the counter used for setting/counting the BCD-coded hour value. The count operation is performed by a carry for each 1 hour of the minute counter.

The assignable range is from 00 through 23 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

Bit:	7	6	5	4	3	2	1	0
	-	-	10 hours		1 hour			
Initial value:	0	0	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	10 hours	Undefined	R/W	Counting Ten's Position of Hours Counts from 0 to 2 for ten's position of hours.
3 to 0	1 hour	Undefined	R/W	Counting One's Position of Hours Counts from 0 to 9, one number per hour. When a carry is generated, 1 is added to the ten's position.

13.3.5 Day of Week Counter (RWKCNT)

RWKCNT is the counter used for setting/counting the BCD-coded day-of-week value. The count operation is performed by a carry for each day of the hour counter.

The assignable range is from 0 through 6 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	Day		
Initial value:	0	0	0	0	0	Undefined	Undefined	Undefined
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	Day	Undefined	R/W	Day-of-Week Counting Day-of-week is indicated with a binary code. 000: Sunday 001: Monday 010: Tuesday 011: Wednesday 100: Thursday 101: Friday 110: Saturday 111: Reserved (setting prohibited)

13.3.6 Day Counter (RDAYCNT)

RDAYCNT is the counter used for setting/counting the BCD-coded day value. The count operation is performed by a carry for each day of the hour counter.

The assignable range is from 01 through 31 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

The assignable range changes depending on the month and in leap years. Confirm the correct setting. A leap year is determined by checking if the year counter (RYRCNT) value is divisible by 400, 100, and 4.

Bit:	7	6	5	4	3	2	1	0
	-	-	10 days		1 day			
Initial value:	0	0	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	10 days	Undefined	R/W	Counting Ten's Position of Days
3 to 0	1 day	Undefined	R/W	Counting One's Position of Days Counts from 0 to 9, one number per day. When a carry is generated, 1 is added to the ten's position.

13.3.7 Month Counter (RMONCNT)

RMONCNT is the counter used for setting/counting the BCD-coded month value. The count operation is performed by a carry for each month of the date counter.

The assignable range is from 01 through 12 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

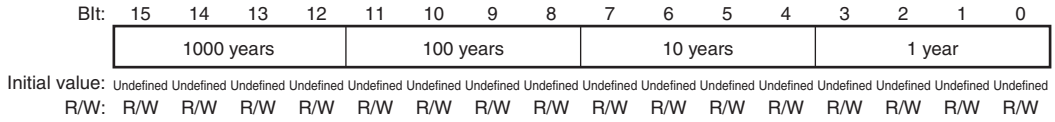
Bit:	7	6	5	4	3	2	1	0
	-	-	-	10 months	1 month			
Initial value:	0	0	0	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	10 months	Undefined	R/W	Counting Ten's Position of Months
3 to 0	1 month	Undefined	R/W	Counting One's Position of Months Counts from 0 to 9, one number per month. When a carry is generated, 1 is added to the ten's position.

13.3.8 Year Counter (RYRCNT)

RYRCNT is the counter used for setting/counting the BCD-coded year value. The count operation is performed by a carry for each year of the month counter.

The assignable range is from 0000 through 9999 (practically in BCD); otherwise an operation error will occur. Carry out write processing after stopping the count operation through the setting of the START bit in RCR2.

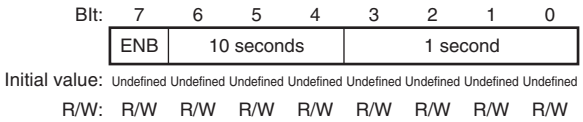


Bit	Bit Name	Initial Value	R/W	Description
15 to 12	1000 years	Undefined	R/W	Counting Thousand's Position of Years
11 to 8	100 years	Undefined	R/W	Counting Hundred's Position of Years
7 to 4	10 years	Undefined	R/W	Counting Ten's Position of Years
3 to 0	1 year	Undefined	R/W	Counting One's Position of Years

13.3.9 Second Alarm Register (RSECAR)

RSECAR is an alarm register corresponding to the BCD-coded second counter RSECCNT. When the ENB bit is set to 1, a comparison with the RSECCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 59 + ENB bits (practically in BCD); otherwise an operation error will occur.



Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RSECCNT value is performed.
6 to 4	10 seconds	Undefined	R/W	Ten's position of seconds setting value
3 to 0	1 second	Undefined	R/W	One's position of seconds setting value

13.3.10 Minute Alarm Register (RMINAR)

RMINAR is an alarm register corresponding to the BCD-coded minute counter RMINCNT. When the ENB bit is set to 1, a comparison with the RMINCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 59 + ENB bits (practically in BCD); otherwise an operation error will occur.

Bit:	7	6	5	4	3	2	1	0
	ENB	10 minutes			1 minute			
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RMINCNT value is performed.
6 to 4	10 minutes	Undefined	R/W	Ten's position of minutes setting value
3 to 0	1 minute	Undefined	R/W	One's position of minutes setting value

13.3.11 Hour Alarm Register (RHRAR)

RHRAR is an alarm register corresponding to the BCD-coded hour counter RHRCNT. When the ENB bit is set to 1, a comparison with the RHRCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 00 through 23 + ENB bits (practically in BCD); otherwise an operation error will occur.

Bit:	7	6	5	4	3	2	1	0
	ENB	-	10 hours		1 hour			
Initial value:	Undefined	0	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RHRCNT value is performed.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	10 hours	Undefined	R/W	Ten's position of hours setting value
3 to 0	1 hour	Undefined	R/W	One's position of hours setting value

13.3.12 Day of Week Alarm Register (RWKAR)

RWKAR is an alarm register corresponding to the BCD-coded day of week counter RWKCNT. When the ENB bit is set to 1, a comparison with the RWKCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 0 through 6 + ENB bits (practically in BCD); otherwise an operation error will occur.

Bit:	7	6	5	4	3	2	1	0
	ENB	-	-	-	-	Day		
Initial value:	Undefined	0	0	0	0	Undefined	Undefined	Undefined
R/W:	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RWKCNT value is performed.
6 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	Day	Undefined	R/W	Day of Week Setting Value 000: Sunday 001: Monday 010: Tuesday 011: Wednesday 100: Thursday 101: Friday 110: Saturday 111: Reserved (setting prohibited)

13.3.13 Day Alarm Register (RDAYAR)

RDAYAR is an alarm register corresponding to the BCD-coded day counter RDAYCNT. When the ENB bit is set to 1, a comparison with the RDAYCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 01 through 31 + ENB bits (practically in BCD); otherwise an operation error will occur.

Bit:	7	6	5	4	3	2	1	0
	ENB	-	10 days		1 day			
Initial value:	Undefined	0	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RDAYCNT value is performed.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	10 days	Undefined	R/W	Ten's position of days setting value
3 to 0	1 day	Undefined	R/W	One's position of days setting value

13.3.14 Month Alarm Register (RMONAR)

RMONAR is an alarm register corresponding to the BCD-coded month counter RMONCNT. When the ENB bit is set to 1, a comparison with the RMONCNT value is performed. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

The assignable range is from 01 through 12 + ENB bits (practically in BCD); otherwise an operation error will occur.

Bit:	7	6	5	4	3	2	1	0
	ENB	-	-	10 months	1 month			
Initial value:	Undefined	0	0	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, a comparison with the RMONCNT value is performed.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	10 months	Undefined	R/W	Ten's position of months setting value
3 to 0	1 month	Undefined	R/W	One's position of months setting value

13.3.15 Year Alarm Register (RYRAR)

RYRAR is an alarm register corresponding to the BCD-coded year counter RYRCNT. The assignable range is from 0000 through 9999 (practically in BCD); otherwise an operation error will occur.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	1000 years				100 years				10 years				1 year			
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	1000 years	Undefined	R/W	Thousand's position of years setting value
11 to 8	100 years	Undefined	R/W	Hundred's position of years setting value
7 to 4	10 years	Undefined	R/W	Ten's position of years setting value
3 to 0	1 year	Undefined	R/W	One's position of years setting value

13.3.16 Control Register 1 (RCR1)

RCR1 is a register that affects carry flags and alarm flags. It also selects whether to generate interrupts for each flag. The CF flag remains undefined until the divider circuit is reset (the RESET and ADJ bits in RCR2 are set to 1). When using the CF flag, make sure to reset the divider circuit beforehand.

The AF flag remains undefined until the value is set to an alarm register and a counter. When using the AF flag, make sure to set the alarm register and counter beforehand.

Bit:	7	6	5	4	3	2	1	0
	CF	-	-	CIE	AIE	-	-	AF
Initial value:	Undefined	0	0	0	0	0	0	Undefined
R/W:	R/W	R	R	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CF	Undefined	R/W	Carry Flag Status flag that indicates that a carry has occurred. CF is set to 1 when a second counter carry is generated or a 64-Hz counter carry is generated while reading the 64-Hz counter A value read from the count register at this time cannot be guaranteed; another read is required. 0: No carry of second counter or no carry of 64-Hz counter while reading 64-Hz counter [Clearing condition] When 0 is written to CF 1: Carry of second counter or carry of 64-Hz counter while reading 64-Hz counter [Setting condition] When a second counter carry is generated or a 64-Hz counter carry is generated while reading the 64-Hz counter, or 1 is written to CF
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CIE	0	R/W	Carry Interrupt Enable Flag When the carry flag (CF) is set to 1, the CIE bit enables an interrupt. 0: A carry interrupt is not generated when the CF flag is set to 1 1: A carry interrupt is generated when the CF flag is set to 1
3	AIE	0	R/W	Alarm Interrupt Enable Flag When the alarm flag (AF) is set to 1, the AIE bit enables an interrupt. 0: An alarm interrupt is not generated when the AF flag is set to 1 1: An alarm interrupt is generated when the AF flag is set to 1
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	AF	Undefined	R/W	Alarm Flag The AF flag is set when the alarm time, which is set by the alarm registers (RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, or RYRAR whose ENB bit is set to 1), and counters match. 0: Alarm registers and counters not match [Clearing condition] When 0 is written to AF 1: Alarm registers and counters match* [Setting condition] When alarm registers (only the registers with ENB bit set to 1) and counters match Note: * Writing 1 holds previous value.

13.3.17 Control Register 2 (RCR2)

RCR2 is a register for periodic interrupt control, 30-second adjustment, divider circuit RESET, and count control.

RCR2 is initialized by a power-on reset or in deep standby mode. The RTCEN bit is only initialized by a power-on reset using the $\overline{RES}$ pin.

Bit:	7	6	5	4	3	2	1	0
	PEF	PES[2:0]			RTCEN	ADJ	RESET	START
Initial value:	0	0	0	0	1	0	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	PEF	0	R/W	Periodic Interrupt Flag Indicates that an interrupt is generated with the period designated by the PES2 to PES0 bits. When set to 1, PEF generates periodic interrupts. 0: Interrupts not generated with the period designated by the bits PES2 to PES0. [Clearing condition] When 0 is written to PEF 1: Interrupts generated with the period designated by the PES2 to PES0 bits. [Setting condition] When an interrupt is generated with the period designated by the bits PES0 to PES2 or when 1 is written to the PEF flag
6 to 4	PES[2:0]	000	R/W	Interrupt Enable Flags These bits specify the period of the periodic interrupt. 000: No periodic interrupts generated 001: Setting prohibited 010: Periodic interrupt generated every 1/64 second 011: Periodic interrupt generated every 1/16 second 100: Periodic interrupt generated every 1/4 second 101: Periodic interrupt generated every 1/2 second 110: Periodic interrupt generated every 1 second 111: Periodic interrupt generated every 2 seconds
3	RTCEN	1	R/W	RTC_X1 Clock Control Controls the function of the RTC_X1 pin. 0: Halts the on-chip crystal oscillator/disables the external clock input. 1: Runs the on-chip crystal oscillator/enables the external clock input. Note: The on-chip crystal oscillator selected with the RCKSEL[1:0] bits in the RCR5 register runs. This bit must not be set to 1 when the RCKSEL[1:0] bits are set to 01.
2	ADJ	0	R/W	30-Second Adjustment When 1 is written to the ADJ bit, times of 29 seconds or less will be rounded down to 00 seconds and 30 seconds or more up to 1 minute. The divider circuit (prescaler and R64CNT) will be simultaneously reset. The ADJ bit is automatically reset to 0; there is no need to write 0 to this bit. This bit is always read as 0. 0: Normal clock operation 1: 30-second adjustment
1	RESET	0	R/W	Reset Writing 1 to this bit initializes the divider circuit, the R64CNT register, the alarm register, the RCR3 register, bits CF and AF in RCR1, and bit PEF in RCR2. In this case, the RESET bit is automatically reset to 0 after 1 is written to and the above registers are reset. Thus, there is no need to write 0 to this bit. This bit is always read as 0. 0: Normal clock operation 1: Divider circuit is reset.
0	START	1	R/W	Start Halts and restarts the counter (clock). 0: Second, minute, hour, day, week, month, and year counters halt. 1: Second, minute, hour, day, week, month, and year counters run normally.

13.3.18 Control Register 3 (RCR3)

When the ENB bit is set to 1, RCR3 performs a comparison with the RYRCNT. From among RSECAR/RMINAR/RHRAR/RWKAR/RDAYAR/RMONAR/RCR3, the counter and alarm register comparison is performed only on those with ENB bits set to 1, and if each of those coincides, an alarm flag of RCR1 is set to 1.

Bit:	7	6	5	4	3	2	1	0
	ENB	-	-	-	-	-	-	-
Initial value:	Undefined	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	ENB	Undefined	R/W	When this bit is set to 1, comparison of the year alarm register (RYRAR) and the year counter (RYRCNT) is performed.
6 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

13.3.19 Control Register 5 (RCR5)

When the RCKSEL[1:0] bits in RCR5 are set to 00 and 01, the RTC_X1 clock pulses (32.768 kHz) and the EXTAL clock pulses are used for clock counting, respectively.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	RCKSEL[1:0]	
Initial value:	0	0	0	0	0	0	Undefined	Undefined
R/W:	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	RCKSEL[1:0]	Undefined	R/W	Operation clock select Operation clock can be selected from RTC_X1 and EXTAL. The setting of these bits should not be switched during operation. 00: Selects RTC_X1 (32.768 kHz). 01: Selects EXTAL. 10: Reserved. 11: Setting prohibited.

13.3.20 Frequency Register H/L (RFRH/L)

RFRH/L is a 16-bit readable/writable register.

The "frequency comparison value" is set in RFC[18:0] so that a 128-Hz clock is generated when the realtime clock operates at the EXTAL clock frequency.

Change the "frequency comparison value" according to the EXTAL clock frequency. The calculation method is shown below. When the RCKSEL bits in RCR5 are set to 00, setting this register is not necessary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SEL64	-	-	-	-	-	-	-	-	-	-	-	-	RFC[18:16]		
Initial value:	Undefined	0	0	0	0	0	0	0	0	0	0	0	0	Undefined	Undefined	Undefined
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFC[15:0]															
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SEL64	Undefined	R/W	64-Hz Divider Select Indicates the EXTAL clock frequency is not dividable by 128 Hz but is dividable by 64 Hz. 0: EXTAL clock frequency is dividable by 128 Hz. 1: EXTAL clock frequency is not dividable by 128 Hz but is dividable by 64 Hz.
30 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 0	RFC[18:0]	Undefined	R/W	Frequency comparison value Sets the comparison value to generate operation clock from the EXTAL clock frequency.

(1) Method for calculating "frequency comparison value".

- When EXTAL clock frequency is dividable by 128 Hz:
  RFC[18:0] = (EXTAL clock frequency)/128
  Clear the SEL64 bit to 0.
- When EXTAL clock frequency is not dividable by 128 Hz but is dividable by 64 Hz:
  RFC[18:0] = (EXTAL clock frequency)/64
  Set the SEL64 bit to 1.

(2) Setting Example

Table 13.3 Setting Example

Clock Frequency		SEL64 Setting Value	RFC Setting Value
EXTAL	10 MHz	0	H'1312D
	11 MHz	1	H'29F63
	12 MHz	0	H'16E36
	13 MHz	1	H'31975

13.4 Operation

A usage example of this module is shown below.

13.4.1 Initial Settings of Registers after Power-On and Oscillation Stabilization Time

All the registers should be initialized after the power is turned on. When the RTC_X1 crystal oscillator is used, oscillation stabilization time is necessary after changing the RTCEN bit in RCR2 from 0 to 1. During oscillation stabilization time, various configurations for or operation of the real time clock must not be performed. For details on oscillation stabilization time, refer to section 47, Electrical Characteristics.

13.4.2 Setting Time

Figure 13.2 shows how to set the time when the clock is stopped.

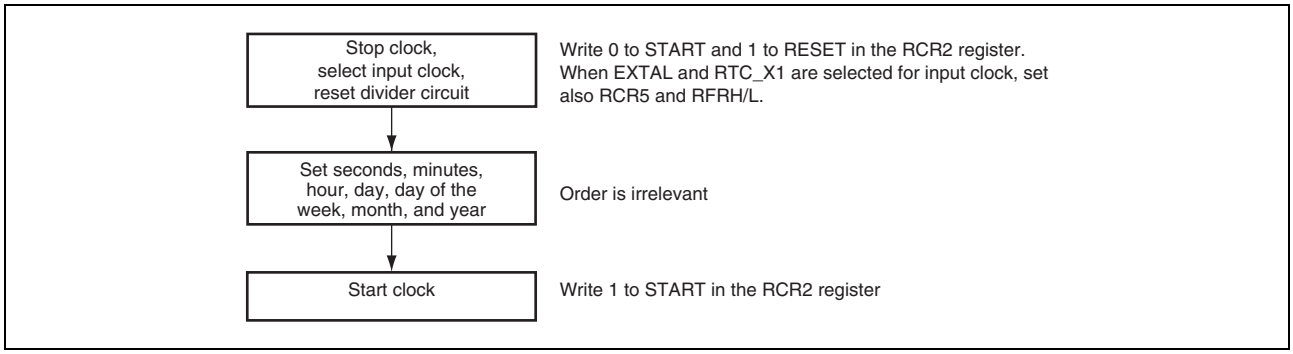


Figure 13.2 Setting Time

13.4.3 Reading Time

Figure 13.3 shows how to read the time.

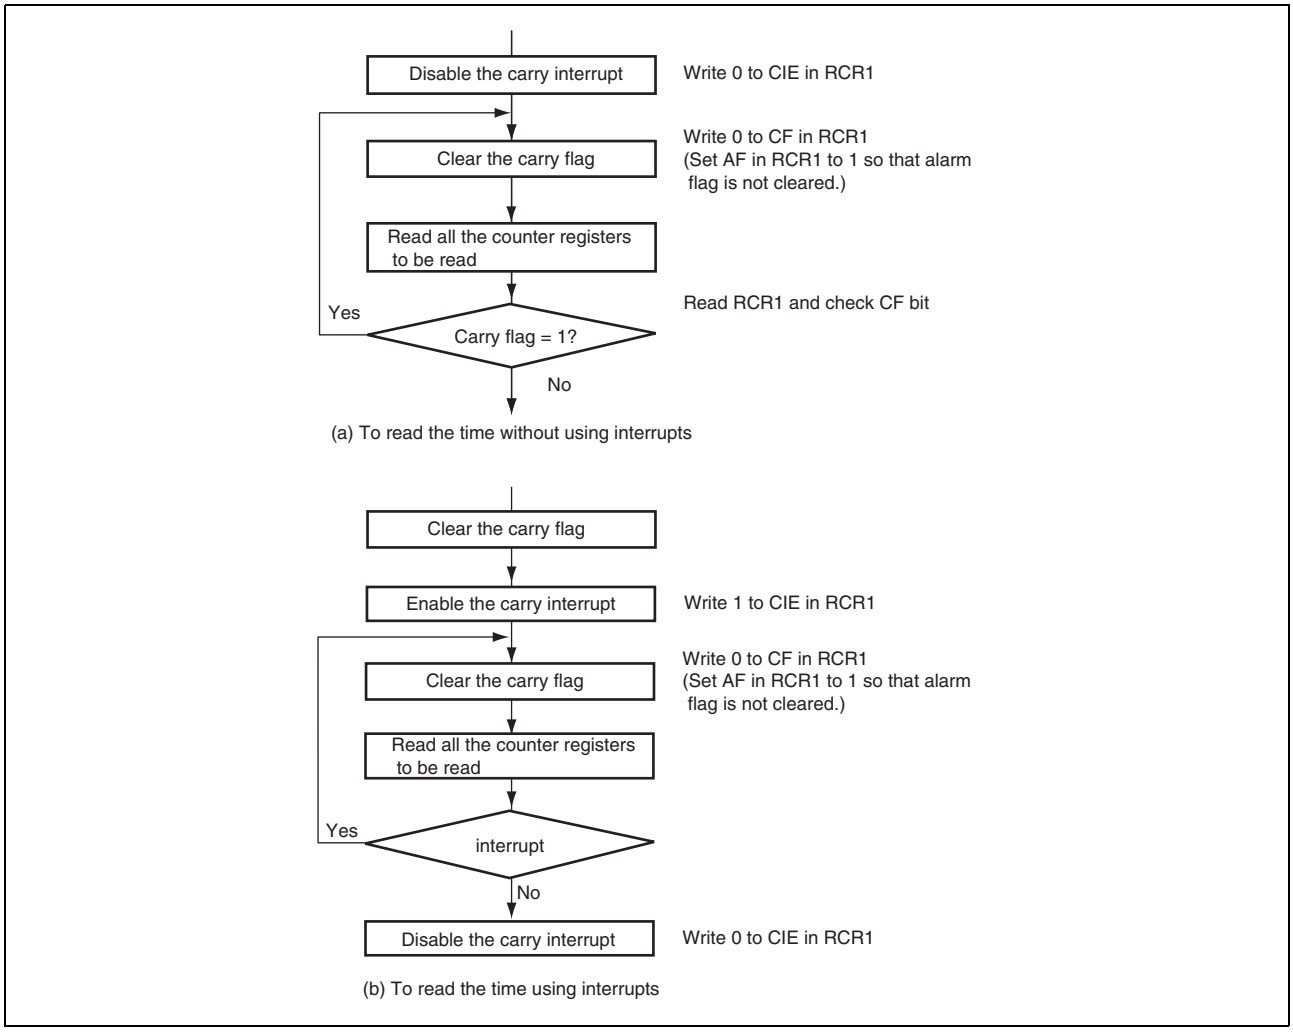

Figure 13.3 Reading Time

If a carry occurs while reading the time, the correct time will not be obtained, so it must be read again. Part (a) in Figure 13.3 shows the method of reading the time without using interrupts; part (b) in Figure 13.3 shows the method using carry interrupts. To keep programming simple, method (a) should normally be used.

13.4.4 Alarm Function

Figure 13.4 shows how to use the alarm function.

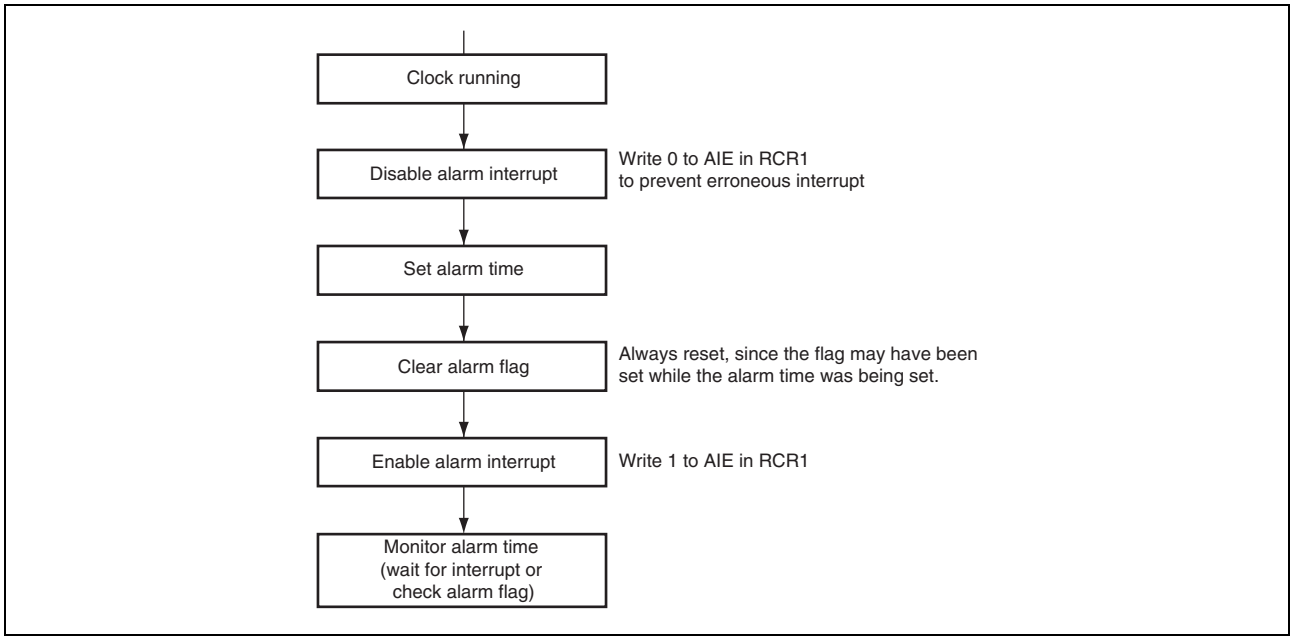

Figure 13.4 Using Alarm Function

Alarms can be generated using seconds, minutes, hours, day of the week, day, month, year, or any combination of these. Set the ENB bit in the register on which the alarm is placed to 1, and then set the alarm time in the lower bits. Clear the ENB bit in the register on which the alarm is not placed to 0.

When the clock and alarm times match, 1 is set in the AF bit in RCR1. Alarm detection can be checked by reading this bit, but normally it is done by interrupt. If 1 is set in the AIE bit in RCR1, an interrupt is generated when an alarm occurs.

The alarm flag is set when the clock and alarm times match. However, the alarm flag can be cleared by writing 0.

13.5 Usage Notes

13.5.1 Register Writing during Count Operation

The following registers cannot be written to during count operation (while the START bit = 1 in RCR2).

RSECCNT, RMINCNT, RHRCNT, RDAYCNT, RWKCNT, RMONCNT, RYRCONT

Count operation must be stopped before writing to any of the above registers.

13.5.2 Use of Realtime Clock Periodic Interrupts

The method of using the periodic interrupt function is shown in Figure 13.5.

A periodic interrupt can be generated periodically at the interval set by bits PES2 to PES0 in RCR2. When the time set by bits PES2 to PES0 has elapsed, the PEF is set to 1.

The PEF is cleared to 0 upon periodic interrupt generation or when bits PES2 to PES0 are set. Periodic interrupt generation can be confirmed by reading this bit, but normally the interrupt function is used.

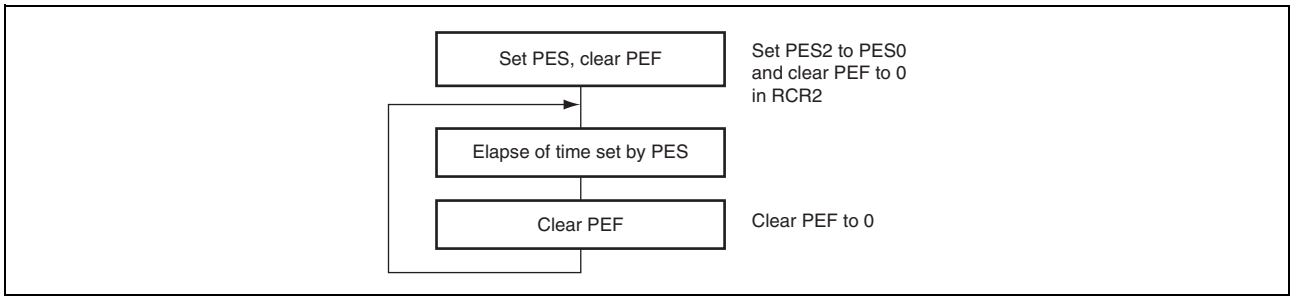

Figure 13.5 Using Periodic Interrupt Function

13.5.3 Transition to Standby Mode after Setting Register

When a transition to standby mode is made after registers in this module are set, sometimes counting is not performed correctly. After the registers are set, be sure to perform one dummy read of the registers before making a transition to standby mode.

13.5.4 Usage Notes when Writing to and Reading the Register

- After writing to the RCR2 register or any of the counters such as the second counter, dummy-read the register twice before reading the actual value. The register contents before the write are returned by the two dummy reads, and the third read returns the register contents reflecting the write.
- Registers other than the above can be read immediately after a write and the written value is reflected.

14. Serial Communication Interface with FIFO

This LSI has a five-channel serial communication interface with FIFO that supports both asynchronous and clock synchronous serial communication. It also has 16-stage FIFO registers for both transmission and reception independently for each channel that enable this LSI to perform efficient high-speed continuous communication.

14.1 Features

- Asynchronous serial communication:
  - Serial data communication is performed by start-stop in character units. This module can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communication interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are eight selectable serial data communication formats.
  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even, odd, or none
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection: Break is detected when a framing error is followed by at least one frame at the space 0 level (low level). It is also detected by reading the RxD pin level directly from the serial port register when a framing error occurs.
- Clock synchronous serial communication:
  - Serial data communication is synchronized with a clock signal. This module can communicate with other chips having a clock synchronous communication function. There is one serial data communication format.
  - Data length: 8 bits
  - Receive error detection: Overrun errors
- Full duplex communication: The transmitting and receiving sections are independent, so this module can transmit and receive simultaneously. Both sections use 16-stage FIFO buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK pin (external)
- Four types of interrupts: Transmit-FIFO-data-empty interrupt, break interrupt, receive-FIFO-data-full interrupt, and receive-error interrupt are requested independently.
- When this module is not in use, it can be stopped by halting the clock supplied to it, saving power.
- In asynchronous mode, on-chip modem control functions ($\overline{\text{RTS}}$ and $\overline{\text{CTS}}$) (only channels 0, 1, and 2).
- The quantity of data in the transmit and receive FIFO data registers and the number of receive errors of the receive data in the receive FIFO data register can be ascertained.
- A time-out error (DR) can be detected when receiving in asynchronous mode.
- In asynchronous mode, the base clock frequency can be either 16 or 8 times the bit rate.
- When an internal clock is selected as a clock source and the SCK pin is used as an input pin in asynchronous mode, either normal mode or double-speed mode can be selected for the baud rate generator.

Figure 14.1 shows a block diagram. However, certain channels do not have the $\overline{\text{CTS}}$ and $\overline{\text{RTS}}$ pins.

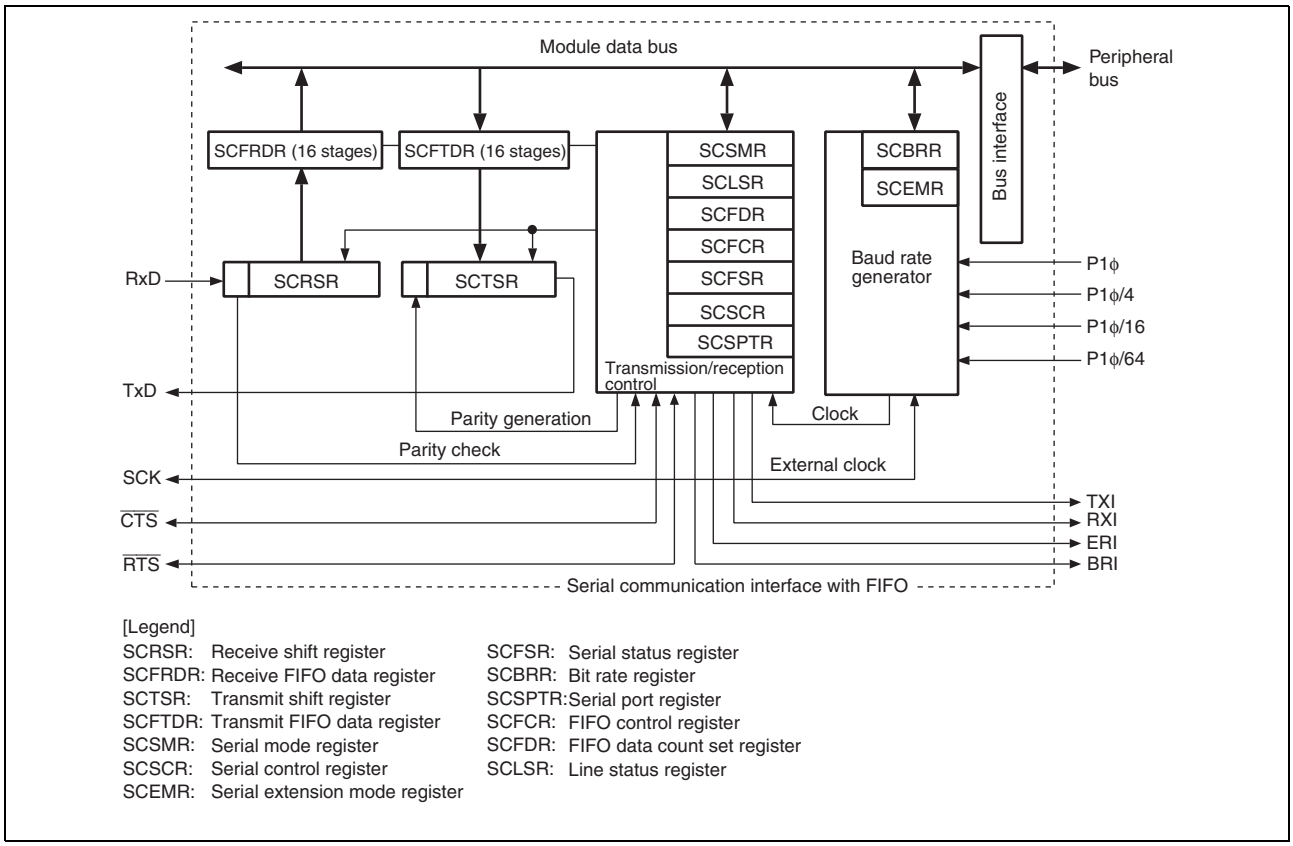

Figure 14.1 Block Diagram

14.2 Input/Output Pins

Table 14.1 shows the pin configuration.

Table 14.1 Pin Configuration

Channel	Pin Name	Symbol	I/O	Function
0 to 4	Serial clock pins	SCK0 to SCK4	I/O	Clock I/O
	Receive data pins	RxD0 to RxD4	Input	Receive data input
	Transmit data pins	TxD0 to TxD4	Output	Transmit data output
0, 1, 2	Request to send pin	$\overline{\text{RTS0}}$, $\overline{\text{RTS1}}$, $\overline{\text{RTS2}}$	I/O	Request to send
	Clear to send pin	$\overline{\text{CTS0}}$, $\overline{\text{CTS1}}$, $\overline{\text{CTS2}}$	I/O	Clear to send

14.3 Register Descriptions

This module has the following registers.

Table 14.2 Register Configuration

Channel	Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
0	Serial mode register_0	SCSMR_0	R/W	H'0000	H'E8007000	16
	Bit rate register_0	SCBRR_0	R/W	H'FF	H'E8007004	8

	Receive FIFO data register_3	SCFRDR_3	R	Undefined	H'E8008814	8
	FIFO control register_3	SCFCR_3	R/W	H'0000	H'E8008818	16
	FIFO data count set register_3	SCFDR_3	R	H'0000	H'E800881C	16
	Serial port register_3	SCSPTR_3	R/W	H'0050	H'E8008820	16
	Line status register_3	SCLSR_3	R/(W)*2	H'0000	H'E8008824	16
	Serial extension mode register_3	SCEMR_3	R/W	H'0000	H'E8008828	16

Channel	Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
4	Serial mode register_4	SCSMR_4	R/W	H'0000	H'E8009000	16
	Bit rate register_4	SCBRR_4	R/W	H'FF	H'E8009004	8
	Serial control register_4	SCSCR_4	R/W	H'0000	H'E8009008	16
	Transmit FIFO data register_4	SCFTDR_4	W	Undefined	H'E800900C	8
	Serial status register_4	SCFSR_4	R/(W)*1	H'0060	H'E8009010	16
	Receive FIFO data register_4	SCFRDR_4	R	Undefined	H'E8009014	8
	FIFO control register_4	SCFCR_4	R/W	H'0000	H'E8009018	16
	FIFO data count set register_4	SCFDR_4	R	H'0000	H'E800901C	16
	Serial port register_4	SCSPTR_4	R/W	H'0050	H'E8009020	16
	Line status register_4	SCLSR_4	R/(W)*2	H'0000	H'E8009024	16
	Serial extension mode register_4	SCEMR_4	R/W	H'0000	H'E8009028	16

Note 1. Only 0 can be written to clear the flag. Bits 15 to 8, 3, and 2 are read-only bits that cannot be modified.
Note 2. Only 0 can be written to clear the flag. Bits 15 to 1 are read-only bits that cannot be modified.

14.3.1 Receive Shift Register (SCRSR)

SCRSR receives serial data. Data input at the RxD pin is loaded into SCRSR in the order received, LSB (bit 0) first, being converted to parallel form. When one byte has been received, it is automatically transferred to the receive FIFO data register (SCFRDR).

The CPU cannot read from or write to SCRSR directly.

Bit:	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-

14.3.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a 16-stage FIFO register that stores serial receive data. The reception of one byte of serial data is complete when the received data is moved from the receive shift register (SCRSR) to SCFRDR for storage. Continuous reception is possible until 16 bytes are stored. The CPU can read but not write to SCFRDR. If data is read when there is no receive data in the SCFRDR, the value is undefined.

When SCFRDR is full of receive data, subsequent serial data is lost.

Bit:	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R

14.3.3 Transmit Shift Register (SCTSR)

SCTSR transmits serial data. Transmit data is loaded from the transmit FIFO data register (SCFTDR) into SCTSR, then the data is transmitted serially from the TxD pin, LSB (bit 0) first. After one data byte has been transmitted, the next transmit data is automatically loaded from SCFTDR into SCTSR and transmission is started again.

The CPU cannot read from or write to SCTSR directly.

Bit:	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-

14.3.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is a 16-stage FIFO register that stores data for serial transmission. When the transmit shift register (SCTSR) empty is detected, transmit data written in the SCFTDR is moved to SCTSR and serial transmission is started. Continuous serial transmission is performed until there is no transmit data left in SCFTDR. The CPU can write to SCFTDR at all times.

When SCFTDR is full of transmit data (16 bytes), no more data can be written. If writing of next data is attempted, the data is ignored.

Bit:	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

14.3.5 Serial Mode Register (SCSMR)

SCSMR specifies the serial communication format and selects the clock source for the baud rate generator.

The CPU can always read from and write to SCSMR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	C/$\overline{A}$	CHR	PE	O/$\overline{E}$	STOP	-	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	C/$\overline{A}$	0	R/W	Communication Mode Selects operating mode from asynchronous and clock synchronous modes. 0: Asynchronous mode 1: Clock synchronous mode
6	CHR	0	R/W	Character Length Selects 7-bit or 8-bit data length in asynchronous mode. In the clock synchronous mode, the data length is always 8 bits, regardless of the CHR setting. 0: 8-bit data 1: 7-bit data* Note: * When 7-bit data is selected, the MSB (bit 7) of the transmit FIFO data register is not transmitted.
5	PE	0	R/W	Parity Enable Selects whether to add a parity bit to transmit data and to check the parity of receive data, in asynchronous mode. In clock synchronous mode, a parity bit is neither added nor checked, regardless of the PE setting. 0: Parity bit not added or checked 1: Parity bit added and checked* Note: * When PE is set to 1, an even or odd parity bit is added to transmit data, depending on the parity mode (O/E) setting. Receive data parity is checked according to the even/odd (O/E) mode setting.
4	O/$\overline{E}$	0	R/W	Parity Mode Selects even or odd parity when parity bits are added and checked. The O/$\overline{E}$ setting is used only in asynchronous mode and only when the parity enable bit (PE) is set to 1 to enable parity addition and checking. The O/$\overline{E}$ setting is ignored in clock synchronous mode or in asynchronous mode when parity addition and checking is disabled. 0: Even parity*1 1: Odd parity*2 Note: 1. If even parity is selected, the parity bit is added to transmit data to make an even number of 1s in the transmitted character and parity bit combined. Receive data is checked to see if it has an even number of 1s in the received character and parity bit combined. 2. If odd parity is selected, the parity bit is added to transmit data to make an odd number of 1s in the transmitted character and parity bit combined. Receive data is checked to see if it has an odd number of 1s in the received character and parity bit combined.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	Stop Bit Length Selects one or two bits as the stop bit length in asynchronous mode. This setting is used only in asynchronous mode. It is ignored in clock synchronous mode because no stop bits are added. When receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit, but if the second stop bit is 0, it is treated as the start bit of the next incoming character. 0: One stop bit When transmitting, a single 1-bit is added at the end of each transmitted character. 1: Two stop bits When transmitting, two 1 bits are added at the end of each transmitted character.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	00	R/W	Clock Select Select the internal clock source of the on-chip baud rate generator. For further information on the clock source, bit rate register settings, and baud rate, see section 14.3.8, Bit Rate Register (SCBRR). 00: P1ϕ 01: P1ϕ/4 10: P1ϕ/16 11: P1ϕ/64 Note: P1ϕ: Peripheral clock

14.3.6 Serial Control Register (SCSCR)

SCSCR enables/disables the transmitter/receiver operation and interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write to SCSCR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	TIE	RIE	TE	RE	REIE	-	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	TIE	0	R/W	Transmit Interrupt Enable Enables or disables the transmit-FIFO-data-empty interrupt (TXI) requested when the serial transmit data is transferred from the transmit FIFO data register (SCFTDR) to the transmit shift register (SCTSR), the quantity of data in the transmit FIFO register becomes less than the specified number of transmission triggers, and then the TDFE flag in the serial status register (SCFSR) is set to 1. 0: Transmit-FIFO-data-empty interrupt request (TXI) is disabled 1: Transmit-FIFO-data-empty interrupt request (TXI) is enabled* Note: * The TXI interrupt request can be cleared by writing a greater quantity of transmit data than the specified transmission trigger number to SCFTDR and clearing TDFE to 0 after reading 1 from TDFE, or by clearing TIE to 0.
6	RIE	0	R/W	Receive Interrupt Enable Enables or disables the receive FIFO data full (RXI) interrupts requested when the RDF flag or DR flag in serial status register (SCFSR) is set to 1, receive-error (ERI) interrupts requested when the ER flag in SCFSR is set to 1, and break (BRI) interrupts requested when the BRK flag in SCFSR or the ORER flag in line status register (SCLSR) is set to 1. 0: Receive FIFO data full interrupt (RXI), receive-error interrupt (ERI), and break interrupt (BRI) requests are disabled 1: Receive FIFO data full interrupt (RXI), receive-error interrupt (ERI), and break interrupt (BRI) requests are enabled* Note: * RXI interrupt requests can be cleared by reading the DR or RDF flag after it has been set to 1, then clearing the flag to 0, or by clearing RIE to 0. ERI or BRI interrupt requests can be cleared by reading the ER, BRK or ORER flag after it has been set to 1, then clearing the flag to 0, or by clearing RIE and REIE to 0.
5	TE	0	R/W	Transmit Enable Enables or disables serial transmission. 0: Serial transmission disabled 1: Serial transmission enabled* Note: * When this bit is set to 1, serial transmission starts after writing of transmit data into SCFTDR. Be sure to select the transmit format in SCSMR and SCFCR and reset the transmit FIFO before setting TE to 1.
4	RE	0	R/W	Receive Enable Enables or disables serial reception. 0: Serial reception disabled*1 1: Serial reception enabled*2 Notes: 1. Clearing RE to 0 does not affect the receive flags (DR, ER, BRK, RDF, FER, PER, and ORER). These flags retain their previous values. 2. When this bit is set to 1, serial reception starts when a start bit is detected in asynchronous mode, or synchronous clock is detected in clock synchronous mode. Be sure to select the receive format in SCSMR and SCFCR and reset the receive FIFO before setting RE to 1.

Bit	Bit Name	Initial Value	R/W	Description
3	REIE	0	R/W	Receive Error Interrupt Enable Enables or disables the receive-error (ERI) interrupts and break (BRI) interrupts. The setting of REIE bit is valid only when RIE bit is set to 0. 0: Receive-error interrupt (ERI) and break interrupt (BRI) requests are disabled 1: Receive-error interrupt (ERI) and break interrupt (BRI) requests are enabled* Note: * ERI or BRI interrupt requests can be cleared by reading the ER, BRK or ORER flag after it has been set to 1, then clearing the flag to 0, or by clearing RIE and REIE to 0. Even if RIE is set to 0, when REIE is set to 1, ERI or BRI interrupt requests are enabled.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKE[1:0]	00	R/W	Clock Enable Select the clock source and enable or disable clock output from the SCK pin. Depending on CKE[1:0], the SCK pin can be used for serial clock output or serial clock input. If synchronous clock output is set in clock synchronous mode, set the C/$\overline{A}$ bit in SCSMR to 1, and then set CKE[1:0]. • Asynchronous mode 00: Internal clock, SCK pin used for input (input signal is ignored) 01: Internal clock, SCK pin used for clock output (The output clock frequency is either 16 or 8 times the bit rate.) 10: External clock, SCK pin used for clock input (The input clock frequency is either 16 or 8 times the bit rate.) 11: Setting prohibited • Clock synchronous mode 00: Internal clock, SCK pin used for synchronous clock output 01: Internal clock, SCK pin used for synchronous clock output 10: External clock, SCK pin used for synchronous clock input 11: Setting prohibited

14.3.7 Serial Status Register (SCFSR)

SCFSR is a 16-bit register. The upper 8 bits indicate the number of receive errors in the receive FIFO data register, and the lower 8 bits indicate the status flag indicating operating state.

The CPU can always read from and write to SCFSR, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, RDF, and DR). These flags can be cleared to 0 only if they have first been read (after being set to 1). The PER flag (bits 15 to 12 and bit 2) and the FER flag (bits 11 to 8 and bit 3) are read-only bits that cannot be written.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PER[3:0]				FER[3:0]				ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Note: * Only 0 can be written to clear the flag after 1 is read.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	PER[3:0]	0000	R	Number of Parity Errors Indicate the quantity of data including a parity error in the receive data stored in the receive FIFO data register (SCFRDR). The value indicated by bits 15 to 12 after the ER bit in SCFSR is set, represents the number of parity errors in SCFRDR. When parity errors have occurred in all 16-byte receive data in SCFRDR, PER[3:0] shows 0000.
11 to 8	FER[3:0]	0000	R	Number of Framing Errors Indicate the quantity of data including a framing error in the receive data stored in SCFRDR. The value indicated by bits 11 to 8 after the ER bit in SCFSR is set, represents the number of framing errors in SCFRDR. When framing errors have occurred in all 16-byte receive data in SCFRDR, FER[3:0] shows 0000.
7	ER	0	R/(W)*	Receive Error Indicates the occurrence of a framing error, or of a parity error when receiving data that includes parity.*1 0: Receiving is in progress or has ended normally [Clearing conditions] • ER is cleared to 0 by a power-on reset • ER is cleared to 0 when 0 is written to after 1 is read from ER 1: A framing error or parity error has occurred. [Setting conditions] • ER is set to 1 when the stop bit is 0 after checking whether or not the last stop bit of the received data is 1 at the end of one data receive operation*2 • ER is set to 1 when the total number of 1s in the receive data plus parity bit does not match the even/odd parity specified by the O/E bit in SCSMR Note: 1. Clearing the RE bit to 0 in SCSCR does not affect the ER bit, which retains its previous value. Even if a receive error occurs, the receive data is transferred to SCFRDR and the receive operation is continued. Whether or not the data read from SCFRDR includes a receive error can be detected by the FER and PER bits in SCFSR. 2. In two stop bits mode, only the first stop bit is checked; the second stop bit is not checked.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R/(W)*	Transmit End Indicates that when the last bit of a serial character was transmitted, SCFTDR did not contain valid data, so transmission has ended. 0: Transmission is in progress [Clearing condition] • TEND is cleared to 0 when 0 is written after 1 is read from TEND after transmit data is written in SCFTDR*1 1: End of transmission [Setting conditions] • TEND is set to 1 by a power-on reset • TEND is set to 1 when TE is cleared to 0 in the serial control register (SCSCR) • TEND is set to 1 when SCFTDR does not contain transmit data when the last bit of a one-byte serial character is transmitted Note: 1. Do not use this bit as a transmit end flag when the direct memory access controller writes data to SCFTDR due to a TXI interrupt request.
5	TDFE	1	R/(W)*	Transmit FIFO Data Empty Indicates that data has been transferred from the transmit FIFO data register (SCFTDR) to the transmit shift register (SCTSR), the quantity of data in SCFTDR has become less than the transmission trigger number specified by the TTRG[1:0] bits in the FIFO control register (SCFCR), and writing of transmit data to SCFTDR is enabled. 0: The quantity of transmit data written to SCFTDR is greater than the specified transmission trigger number [Clearing conditions] • TDFE is cleared to 0 when data exceeding the specified transmission trigger number is written to SCFTDR after 1 is read from TDFE and then 0 is written to TDFE • TDFE is cleared to 0 when direct memory access controller is activated by transmit FIFO data empty interrupt (TXI) and data exceeding the specified transmission trigger number is written to SCFTDR 1: The quantity of transmit data in SCFTDR is less than or equal to the specified transmission trigger number*1 [Setting conditions] • TDFE is set to 1 by a power-on reset • TDFE is set to 1 when the quantity of transmit data in SCFTDR becomes less than or equal to the specified transmission trigger number as a result of transmission Note: 1. Since SCFTDR is a 16-byte FIFO register, the maximum quantity of data that can be written when TDFE is 1 is "16 minus the specified transmission trigger number". If an attempt is made to write additional data, the data is ignored. The quantity of data in SCFTDR is indicated by the upper 8 bits of SCFDR.
4	BRK	0	R/(W)*	Break Detection Indicates that a break signal has been detected in receive data. 0: No break signal received [Clearing conditions] • BRK is cleared to 0 by a power-on reset • BRK is cleared to 0 when software reads BRK after it has been set to 1, then writes 0 to BRK 1: Break signal received*1 [Setting condition] • BRK is set to 1 when data including a framing error is received, followed by at least one frame at the space 0 level (low level) Note: 1. When a break is detected, transfer of the receive data (H'00) to SCFRDR stops after detection. When the break ends and the receive signal becomes mark 1, the transfer of receive data resumes.

Bit	Bit Name	Initial Value	R/W	Description
3	FER	0	R	Framing Error Indication Indicates a framing error in the data read from the receive FIFO data register (SCFRDR) in asynchronous mode. 0: No receive framing error occurred in the next data read from SCFRDR [Clearing conditions] • FER is cleared to 0 by a power-on reset • FER is cleared to 0 when no framing error is present in the next data read from SCFRDR 1: A receive framing error occurred in the next data read from SCFRDR [Setting condition] • FER is set to 1 when a framing error is present in the next data read from SCFRDR
2	PER	0	R	Parity Error Indication Indicates a parity error in the data read from the receive FIFO data register (SCFRDR) in asynchronous mode. 0: No receive parity error occurred in the next data read from SCFRDR [Clearing conditions] • PER is cleared to 0 by a power-on reset • PER is cleared to 0 when no parity error is present in the next data read from SCFRDR 1: A receive parity error occurred in the next data read from SCFRDR [Setting condition] • PER is set to 1 when a parity error is present in the next data read from SCFRDR
1	RDF	0	R/(W)*	Receive FIFO Data Full Indicates that receive data has been transferred to the receive FIFO data register (SCFRDR), and the quantity of data in SCFRDR has become more than the receive trigger number specified by the RTRG[1:0] bits in the FIFO control register (SCFCR). 0: The quantity of transmit data written to SCFRDR is less than the specified receive trigger number [Clearing conditions] • RDF is cleared to 0 by a power-on reset • RDF is cleared to 0 when the SCFRDR is read until the quantity of receive data in SCFRDR becomes less than the specified receive trigger number after 1 is read from RDF, and then 0 is written • RDF is cleared to 0 when the direct memory access controller is activated by receive FIFO data full interrupt (RXI) and SCFRDR is read until the quantity of receive data in it becomes less than the specified receive trigger number 1: The quantity of receive data in SCFRDR is equal to or greater than the specified receive trigger number [Setting condition] • RDF is set to 1 when a quantity of receive data equal to or greater than the specified receive trigger number is stored in SCFRDR*1 Note: 1. As SCFRDR is a 16-byte FIFO register, the maximum quantity of data that can be read when RDF is 1 is the specified receive trigger number. If an attempt is made to read after all the data in SCFRDR has been read, the data is undefined. The quantity of receive data in SCFRDR is indicated by the lower 8 bits of SCFDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	Receive Data Ready Indicates that the quantity of data in the receive FIFO data register (SCFRDR) is less than the specified receive trigger number, and that the next data has not yet been received after the elapse of 15 ETU from the last stop bit in asynchronous mode. In clock synchronous mode, this bit is not set to 1. 0: Receiving is in progress, or no receive data remains in SCFRDR after receiving ended normally [Clearing conditions] • DR is cleared to 0 by a power-on reset • DR is cleared to 0 when all receive data are read from SCFRDR after 1 is read from DR, and then 0 is written. • DR is cleared to 0 when all receive data are read from SCFRDR after the direct memory access controller is activated by receive FIFO data full interrupt (RXI). 1: Next receive data has not been received [Setting condition] • DR is set to 1 when SCFRDR contains less data than the specified receive trigger number, and the next data has not yet been received after the elapse of 15 ETU from the last stop bit.*1 Note: 1. This is equivalent to 1.5 frames with the 8-bit, 1-stop-bit format. (ETU: elementary time unit)

Note: * Only 0 can be written to clear the flag after 1 is read.

14.3.8 Bit Rate Register (SCBRR)

SCBRR is an 8-bit register that is used with the CKS[1:0] bits in the serial mode register (SCSMR) and the BGDM and ABCS bits in the serial extension mode register (SCEMR) to determine the serial transmit/receive bit rate.

The CPU can always read from and write to SCBRR. SCBRR is initialized to H'FF by a power-on reset. Each channel has independent baud rate generator control, so different values can be set in eight channels.

Bit:	7	6	5	4	3	2	1	0
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The SCBRR setting is calculated as follows:

- Asynchronous mode:

When baud rate generator operates in normal mode (when the BGDM bit of SCEMR is 0):

$$N = \frac{P1\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$ (Operation on a base clock with a frequency of 16 times the bit rate)

$$N = \frac{P1\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$ (Operation on a base clock with a frequency of 8 times the bit rate)

When baud rate generator operates in double speed mode (when the BGDM bit of SCEMR is 1):

$$N = \frac{P1\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$ (Operation on a base clock with a frequency of 16 times the bit rate)

$$N = \frac{P1\phi}{16 \times 2^{2n-1} \times B} \times 10^6 - 1$$ (Operation on a base clock with a frequency of 8 times the bit rate)

- Clock synchronous mode:

$$N = \frac{P1\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bits/s)
N: SCBRR setting for baud rate generator ($0 \leq N \leq 255$)
(The setting must satisfy the electrical characteristics.)
P1ϕ: Operating frequency for peripheral modules (MHz)
n: Baud rate generator clock source (n = 0, 1, 2, 3) (for the clock sources and values of n, see Table 14.3.)

Table 14.3 SCSMR Settings

		SCSMR Settings	
n	**Clock Source**	**CKS[1]**	**CKS[0]**
0	P1ϕ	0	0
1	P1ϕ/4	0	1
2	P1ϕ/16	1	0
3	P1ϕ/64	1	1

The bit rate error in asynchronous mode is given by the following formula:

When baud rate generator operates in normal mode (the BGDM bit of SCEMR is 0):

$$\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$ (Operation on a base clock with a frequency of 16 times the bit rate)

$$\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{(N+1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$ (Operation on a base clock with a frequency of 8 times the bit rate)

When baud rate generator operates in double speed mode (the BGDM bit of SCEMR is 1):

$$\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{(N+1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$ (Operation on a base clock with a frequency of 16 times the bit rate)

$$\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{(N+1) \times B \times 16 \times 2^{2n-1}} - 1 \right\} \times 100$$ (Operation on a base clock with a frequency of 8 times the bit rate)

Table 14.4 lists the sample SCBRR settings in asynchronous mode in which a base clock frequency is 16 times the bit rate (the ABCS bit in SCEMR is 0) and the baud rate generator operates in normal mode (the BGDM bit in SCEMR is 0), and Table 14.5 lists the sample SCBRR settings in clock synchronous mode.

Table 14.4 Bit Rates and SCBRR Settings (Asynchronous Mode, BGDM = 0, ABCS = 0)

	P1ϕ (MHz)					
	50			66.67		
Bit Rate (bits/s)	n	N	Error (%)	n	N	Error (%)
110	3	221	-0.02			
150	3	162	-0.15	3	216	0.01
300	3	80	0.47	3	108	-0.45

14.3.9 FIFO Control Register (SCFCR)

SCFCR resets the quantity of data in the transmit and receive FIFO data registers, sets the trigger data quantity, and contains an enable bit for loop-back testing. SCFCR can always be read and written to by the CPU.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RFRST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	RSTRG[2:0]	000	R/W	$\overline{\text{RTS}}$ Output Active Trigger When the quantity of receive data in receive FIFO data register (SCFRDR) becomes equal to or greater than the trigger set number shown below, $\overline{\text{RTS}}$ signal is set to high. 000: 15 001: 1 010: 4 011: 6 100: 8 101: 10 110: 12 111: 14
7, 6	RTRG[1:0]	00	R/W	Receive FIFO Data Trigger Set the quantity of receive data which sets the receive data full (RDF) flag in the serial status register (SCFSR). The RDF flag is set to 1 when the quantity of receive data stored in the receive FIFO data register (SCFRDR) becomes equal to or greater than the set trigger number shown below. • Asynchronous mode 00: 1 01: 4 10: 8 11: 14 • Clock synchronous mode 00: 1 01: 2 10: 8 11: 14 Note: In clock synchronous mode, to transfer the receive data using the direct memory access controller, set the receive trigger number to 1. If set to other than 1, CPU must read the receive data left in SCFRDR.
5, 4	TTRG[1:0]	00	R/W	Transmit FIFO Data Trigger Set the quantity of remaining transmit data which sets the transmit FIFO data register empty (TDFE) flag in the serial status register (SCFSR). The TDFE flag is set to 1 when the quantity of transmit data in the transmit FIFO data register (SCFTDR) becomes equal to or less than the set trigger number shown below. 00: 8 (8)* 01: 4 (12)* 10: 2 (14)* 11: 0 (16)* Note: * Values in parentheses mean the number of empty bytes in SCFTDR when the TDFE flag is set to 1.
3	MCE	0	R/W	Modem Control Enable Enables modem control signals $\overline{\text{CTS}}$ and $\overline{\text{RTS}}$. For channels 3 and 4 in clock synchronous mode, MCE bit should always be 0. 0: Modem signal disabled* 1: Modem signal enabled Note: * $\overline{\text{CTS}}$ is fixed at active 0 regardless of the input value, and $\overline{\text{RTS}}$ is also fixed at 0.

Bit	Bit Name	Initial Value	R/W	Description
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Disables the transmit data in the transmit FIFO data register and resets the register to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * Reset operation is executed by a power-on reset.
1	RFRST	0	R/W	Receive FIFO Data Register Reset Disables the receive data in the receive FIFO data register and resets the register to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * Reset operation is executed by a power-on reset.
0	LOOP	0	R/W	Loop-Back Test Internally connects the transmit output pin (TxD) and receive input pin (RxD) and internally connects the $\overline{\text{RTS}}$ pin and $\overline{\text{CTS}}$ pin and enables loop-back testing. 0: Loop back test disabled 1: Loop back test enabled

14.3.10 FIFO Data Count Set Register (SCFDR)

SCFDR is a 16-bit register which indicates the quantity of data stored in the transmit FIFO data register (SCFTDR) and the receive FIFO data register (SCFRDR).

It indicates the quantity of transmit data in SCFTDR with the upper 8 bits, and the quantity of receive data in SCFRDR with the lower 8 bits. SCFDR can always be read by the CPU.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	T[4:0]					-	-	-	R[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	T[4:0]	00000	R	T4 to T0 bits indicate the quantity of non-transmitted data stored in SCFTDR. H'00 means no transmit data, and H'10 means that all transmit data is stored in SCFTDR.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	R[4:0]	00000	R	R4 to R0 bits indicate the quantity of receive data stored in SCFRDR. H'00 means no receive data, and H'10 means that all receive data is stored in SCFRDR.

14.3.11 Serial Port Register (SCSPTR)

SCSPTR controls input/output and data of pins multiplexed to the functions of this module. Bits 7 and 6 can control input/output data of $\overline{\text{RTS}}$ pin. Bits 5 and 4 can control input/output data of $\overline{\text{CTS}}$ pin. Bits 3 and 2 can control input/output data of SCK pin. Bits 1 and 0 can input data from RxD pin and output data to TxD pin, so they control break of serial transmitting/receiving.

The CPU can always read and write to SCSPTR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB2IO	SPB2DT
Initial value:	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	0	R/W	$\overline{\text{RTS}}$ Port Input/Output Specifies input or output for the serial port $\overline{\text{RTS}}$ pin. When the $\overline{\text{RTS}}$ pin is actually used as a port outputting the RTSDT bit value, the MCE bit in SCFCR should be cleared to 0. 0: RTSDT bit value not output to $\overline{\text{RTS}}$ pin 1: RTSDT bit value output to $\overline{\text{RTS}}$ pin
6	RTSDT	1	R/W	$\overline{\text{RTS}}$ Port Data Specifies the input/output data of the serial port $\overline{\text{RTS}}$ pin. Input/output is specified by the RTSIO bit. For output, the RTSDT bit value is output to the $\overline{\text{RTS}}$ pin. The $\overline{\text{RTS}}$ pin status is read from the RTSDT bit regardless of the RTSIO bit setting. However, $\overline{\text{RTS}}$ input/output must be set in the general purpose I/O ports. 0: Input/output data is low level 1: Input/output data is high level
5	CTSIO	0	R/W	$\overline{\text{CTS}}$ Port Input/Output Specifies input or output for the serial port $\overline{\text{CTS}}$ pin. When the $\overline{\text{CTS}}$ pin is actually used as a port outputting the CTSDT bit value, the MCE bit in SCFCR should be cleared to 0. 0: CTSDT bit value not output to $\overline{\text{CTS}}$ pin 1: CTSDT bit value output to $\overline{\text{CTS}}$ pin
4	CTSDT	1	R/W	$\overline{\text{CTS}}$ Port Data Specifies the input/output data of the serial port $\overline{\text{CTS}}$ pin. Input/output is specified by the CTSIO bit. For output, the CTSDT bit value is output to the $\overline{\text{CTS}}$ pin. The $\overline{\text{CTS}}$ pin status is read from the CTSDT bit regardless of the CTSIO bit setting. However, $\overline{\text{CTS}}$ input/output must be set in the general purpose I/O ports. 0: Input/output data is low level 1: Input/output data is high level
3	SCKIO	0	R/W	SCK Port Input/Output Specifies input or output for the serial port SCK pin. When the SCK pin is actually used as a port outputting the SCKDT bit value, the CKE[1:0] bits in SCSCR should be cleared to 0. 0: SCKDT bit value not output to SCK pin 1: SCKDT bit value output to SCK pin
2	SCKDT	0	R/W	SCK Port Data Specifies the input/output data of the serial port SCK pin. Input/output is specified by the SCKIO bit. For output, the SCKDT bit value is output to the SCK pin. The SCK pin status is read from the SCKDT bit regardless of the SCKIO bit setting. However, SCK input/output must be set in the general purpose I/O ports. 0: Input/output data is low level 1: Input/output data is high level

Bit	Bit Name	Initial Value	R/W	Description
1	SPB2IO	0	R/W	Serial Port Break Input/Output Specifies input or output for the serial port TxD pin. When the TxD pin is actually used as a port outputting the SPB2DT bit value, the TE bit in SCSCR should be cleared to 0. 0: SPB2DT bit value not output to TxD pin 1: SPB2DT bit value output to TxD pin
0	SPB2DT	0	R/W	Serial Port Break Data Specifies the input data of the RxD pin and the output data of the TxD pin used as serial ports. Input/output is specified by the SPB2IO bit. When the TxD pin is set to output, the SPB2DT bit value is output to the TxD pin. The RxD pin status is read from the SPB2DT bit regardless of the SPB2IO bit setting. However, RxD input and TxD output must be set in the general purpose I/O ports. 0: Input/output data is low level 1: Input/output data is high level

14.3.12 Line Status Register (SCLSR)

The CPU can always read or write to SCLSR, but cannot write 1 to the ORER flag. This flag can be cleared to 0 only if it has first been read (after being set to 1).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ORER
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*

Note: * Only 0 can be written to clear the flag after 1 is read.

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ORER	0	R/(W)*	Overrun Error Indicates the occurrence of an overrun error during reception. 0: Receiving is in progress or has ended normally*1 [Clearing conditions] • ORER is cleared to 0 by a power-on reset • ORER is cleared to 0 when 0 is written after 1 is read from ORER. 1: An overrun error has occurred during reception*2 [Setting condition] • ORER is set to 1 when the next serial receiving is finished while the receive FIFO is full of 16-byte receive data. Note: 1. Clearing the RE bit to 0 in SCSCR does not affect the ORER bit, which retains its previous value. 2. The receive FIFO data register (SCFRDR) retains the data before an overrun error has occurred, and the next received data is discarded. When the ORER bit is set to 1, the next serial reception cannot be continued.

14.3.13 Serial Extension Mode Register (SCEMR)

The CPU can always read from or write to SCEMR. Setting the BGDM bit in this register to 1 allows the baud rate generator in this module to operate in double-speed mode when asynchronous mode is selected (by setting the C/$\overline{A}$ bit in SCSMR to 0) and an internal clock is selected as a clock source and the SCK pin is set as an input pin (by setting the CKE[1:0] bits in SCSCR to 00).
The base clock frequency within a bit period in asynchronous mode can be switched by the setting of the ABCS bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	BGDM	-	-	-	-	-	-	ABCS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	BGDM	0	R/W	Baud Rate Generator Double-Speed Mode When the BGDM bit is set to 1, the baud rate generator in this module operates in double-speed mode. This bit is valid only when asynchronous mode is selected by setting the C/$\overline{A}$ bit in SCSMR to 0 and an internal clock is selected as a clock source and the SCK pin is set as an input pin by setting the CKE[1:0] bits in SCSCR to 00. In other settings, use normal mode. 0: Normal mode 1: Double-speed mode
6 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ABCS	0	R/W	Base Clock Select in Asynchronous Mode This bit selects the base clock frequency within a bit period in asynchronous mode. This bit is valid only in asynchronous mode (when the C/$\overline{A}$ bit in SCSMR is 0). 0: Base clock frequency is 16 times the bit rate 1: Base clock frequency is 8 times the bit rate

14.4 Operation

14.4.1 Overview

For serial communication, this module has an asynchronous mode in which characters are synchronized individually, and a clock synchronous mode in which communication is synchronized with clock pulses.

This module has a 16-stage FIFO buffer for both transmission and reception, reducing the overhead of the CPU, and enabling continuous high-speed communication. Furthermore, channels 0, 1, and 2 have $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ signals to be used as modem control signals.

The transmission/reception format is selected in the serial mode register (SCSMR), as shown in Table 14.9. The clock source is selected by the combination of the C/$\overline{\text{A}}$ bit in SCSMR and the CKE[1:0] bits in the serial control register (SCSCR), as shown in Table 14.10.

(1) Asynchronous Mode

- Data length is selectable: 7 or 8 bits
- Parity bit is selectable. So is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors, parity errors, receive FIFO data full, overrun errors, receive data ready, and breaks.
- The number of stored data bytes is indicated for both the transmit and receive FIFO registers.
- An internal or external clock can be selected as the clock source.
  - When an internal clock is selected, this module operates using the clock of on-chip baud rate generator.
  - When an external clock is selected, the external clock input must have a frequency 16 or 8 times the bit rate. (The on-chip baud rate generator is not used.)

(2) Clock Synchronous Mode

- The transmission/reception format has a fixed 8-bit data length.
- In receiving, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the clock source.
  - When an internal clock is selected, this module operates using the clock of the on-chip baud rate generator, and outputs this clock to external devices as the synchronous clock.
  - When an external clock is selected, this module operates on the input external synchronous clock not using the on-chip baud rate generator.

Table 14.9 SCSMR Settings and Communication Formats

SCSMR Settings					Communication Format		
Bit 7 C/$\overline{A}$	**Bit 6 CHR**	**Bit 5 PE**	**Bit 3 STOP**	**Mode**	**Data Length**	**Parity Bit**	**Stop Bit Length**
0	0	0	0	Asynchronous	8 bits	Not set	1 bit
			1				2 bits
		1	0			Set	1 bit
			1				2 bits
	1	0	0		7 bits	Not set	1 bit
			1				2 bits
		1	0			Set	1 bit
			1				2 bits
1	x	x	x	Clock synchronous	8 bits	Not set	None

[Legend]
x: Don't care

Table 14.10 SCSMR and SCSCR Settings and Clock Source Selection

SCSMR	SCSCR			
Bit 7 C/$\overline{A}$	**Bit 1, 0 CKE[1:0]**	**Mode**	**Clock Source**	**SCK Pin Function**
0	00	Asynchronous	Internal	This module does not use the SCK pin.
	01			Outputs a clock with a frequency 16/8 times the bit rate
	10		External	Inputs a clock with frequency 16/8 times the bit rate
	11		Setting prohibited	
1	0x	Clock synchronous	Internal	Outputs the synchronous clock
	10		External	Inputs the synchronous clock
	11		Setting prohibited	

[Legend]
x: Don't care
Note: When using the baud rate generator in double-speed mode (BGMD = 1), select asynchronous mode by setting the C/$\overline{A}$ bit to 0, and select an internal clock as a clock source and the SCK pin is not used (the CKE[1:0] bits set to 00).

14.4.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections in this module are independent, so full duplex communication is possible. The transmitter and receiver are 16-stage FIFO buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 14.2 shows the general format of asynchronous serial communication.

In asynchronous serial communication, the communication line is normally held in the mark (high) state. This module monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit.

One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order. When receiving in asynchronous mode, this module synchronizes at the falling edge of the start bit. This module samples each data bit on the eighth or fourth pulse of a clock with a frequency 16 or 8 times the bit rate; receive data is latched at the center of each bit.

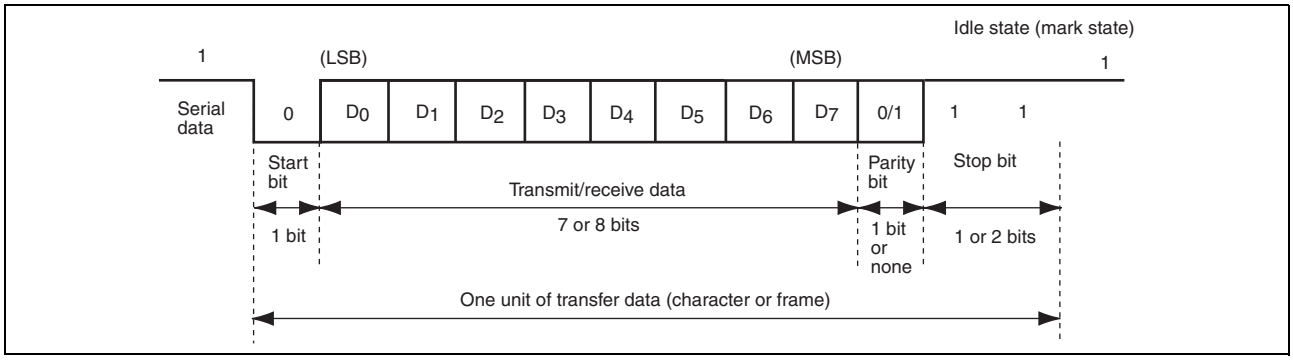

Figure 14.2 Example of Data Format in Asynchronous Communication (8-Bit Data with Parity and Two Stop Bits)

(1) Transmit/Receive Formats

Table 14.11 lists the eight communication formats that can be selected in asynchronous mode. The format is selected by settings in the serial mode register (SCSMR).

Table 14.11 Serial Communication Formats (Asynchronous Mode)

SCSMR Bits			Serial Transmit/Receive Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	START	8-bit data								STOP		
0	0	1	START	8-bit data								STOP	STOP	
0	1	0	START	8-bit data								P	STOP	
0	1	1	START	8-bit data								P	STOP	STOP
1	0	0	START	7-bit data							STOP			
1	0	1	START	7-bit data							STOP	STOP		
1	1	0	START	7-bit data							P	STOP		
1	1	1	START	7-bit data							P	STOP	STOP	

[Legend]
START: Start bit
STOP: Stop bit
P: Parity bit

(2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the transmit/receive clock. The clock source is selected by the C/$\overline{A}$ bit in the serial mode register (SCSMR) and the CKE[1:0] bits in the serial control register (SCSCR). For clock source selection, refer to Table 14.10, SCSMR and SCSCR Settings and Clock Source Selection.

When an external clock is input at the SCK pin, it must have a frequency equal to 16 or 8 times the desired bit rate. When this module operates on an internal clock, it can output a clock signal on the SCK pin. The frequency of this output clock is 16 or 8 times the desired bit rate.

(3) Transmitting and Receiving Data

- Initialization (Asynchronous Mode)
  Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize this module as follows.
  When changing the operation mode or the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing TE and RE to 0, however, does not initialize the serial status register (SCFSR), transmit FIFO data register (SCFTDR), or receive FIFO data register (SCFRDR), which retain their previous contents. Clear TE to 0 after all transmit data has been transmitted and the TEND flag in the SCFSR is set. The TE bit can be cleared to 0 during transmission, but the transmit data goes to the Mark state after the bit is cleared to 0. Set the TFRST bit in SCFCR to 1 and reset SCFTDR before TE is set again to start transmission.
  When an external clock is used, the clock should not be stopped during initialization or subsequent operation. The operation becomes unreliable if the clock is stopped.

Figure 14.3 shows a sample flowchart for initialization.

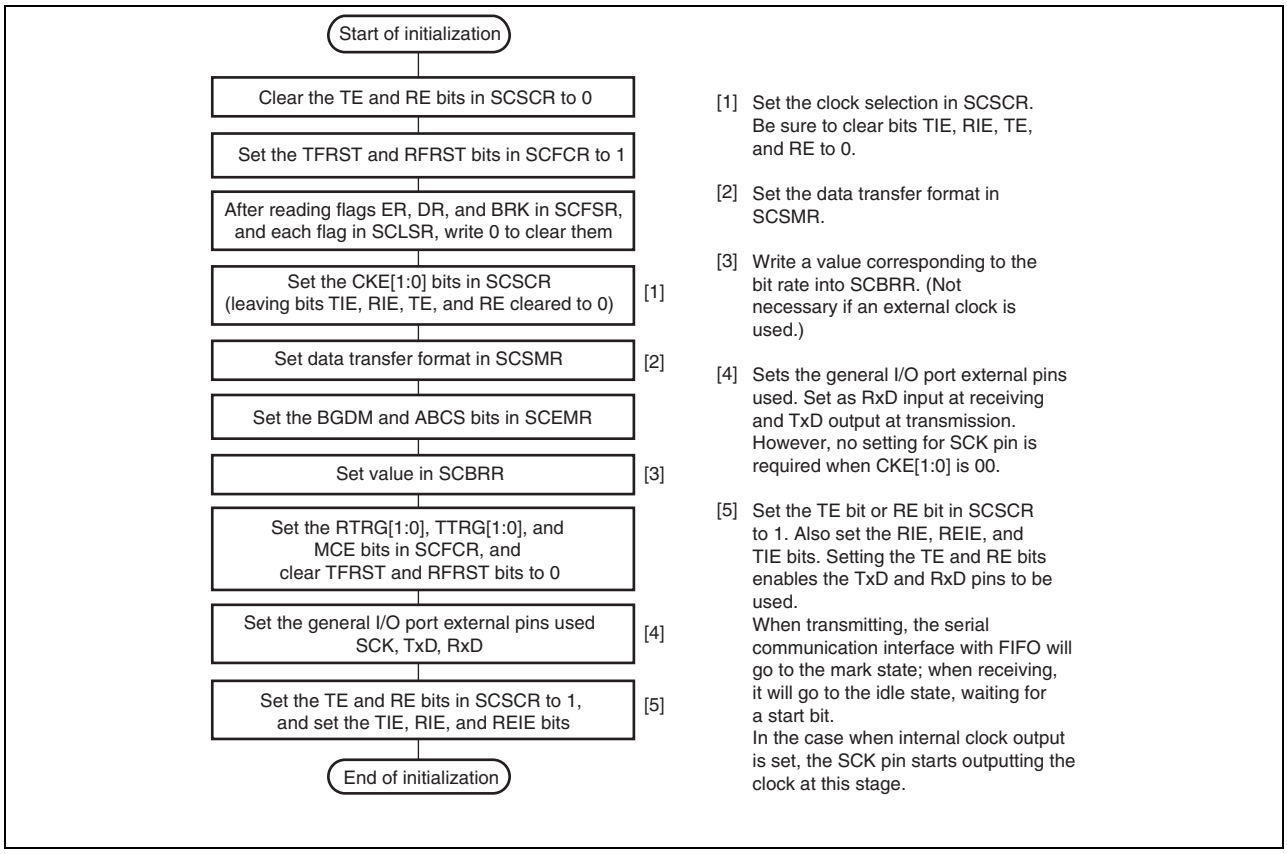

Figure 14.3 Sample Flowchart for Initialization

- Transmitting Serial Data (Asynchronous Mode)

  Figure 14.4 shows a sample flowchart for serial transmission.

  Use the following procedure for serial data transmission after enabling transmission.

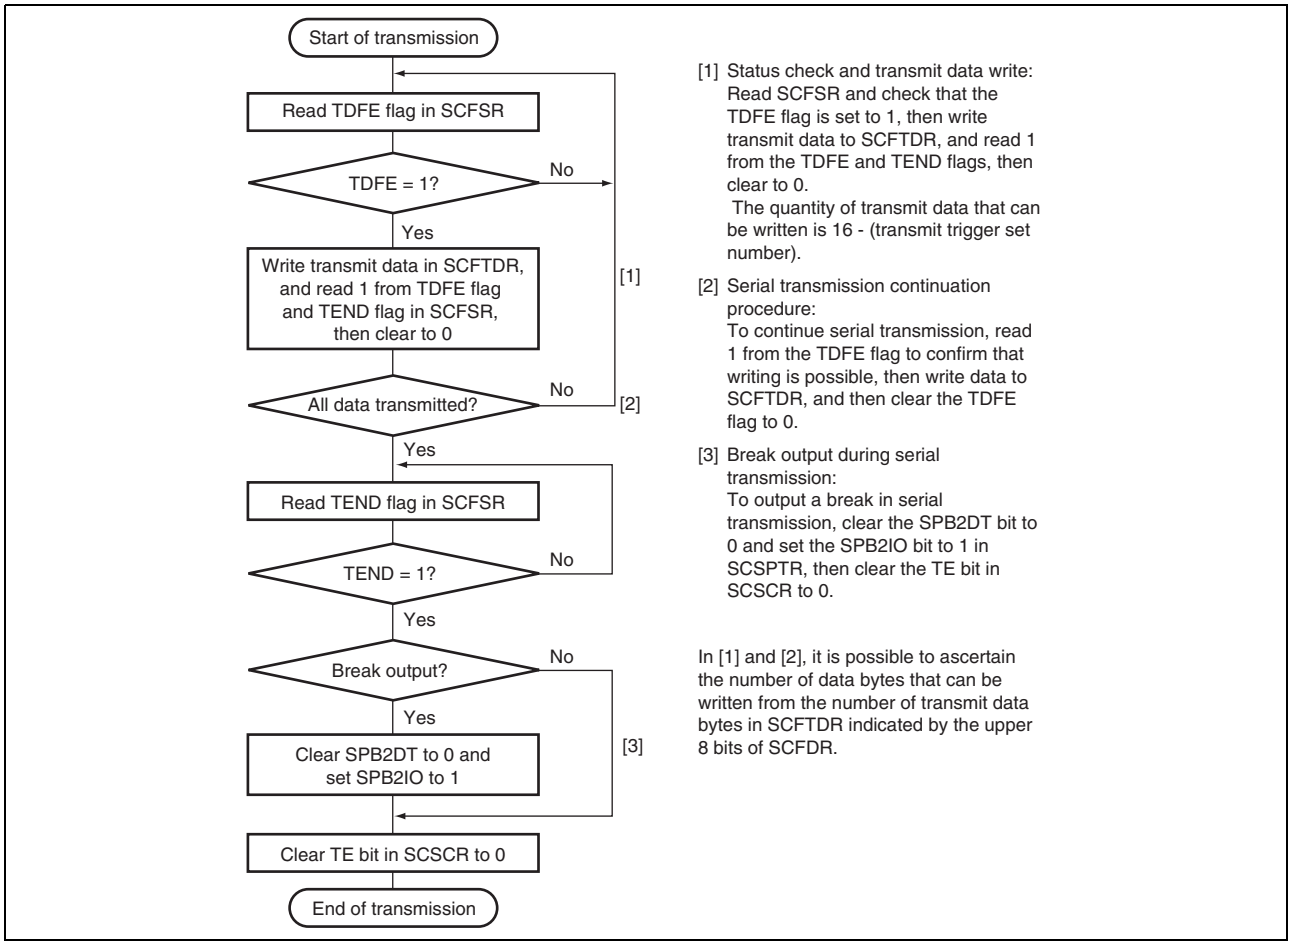

Figure 14.4 Sample Flowchart for Transmitting Serial Data

In serial transmission, this module operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the data is transferred from SCFTDR to the transmit shift register (SCTSR). Confirm that the TDFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 – transmit trigger setting).

2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR becomes equal to or less than the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.
   The serial transmit data is sent from the TxD pin in the following order.

   A. Start bit: One-bit 0 is output.
   B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
   D. Stop bit(s): One or two 1 bits (stop bits) are output.
   E. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.

3. The SCFTDR transmit data is checked at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.

Figure 14.5 shows an example of the operation for transmission.

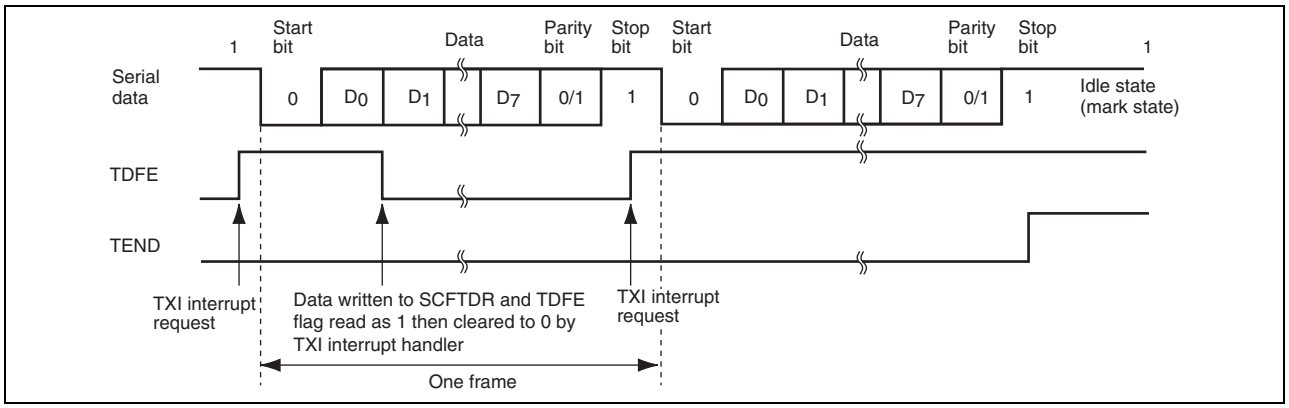

Figure 14.5 Example of Transmit Operation (8-Bit Data, Parity, 1 Stop Bit)

4. When modem control is enabled in channels 0, 1, and 2, transmission can be stopped and restarted in accordance with the $\overline{\text{CTS}}$ input value. When $\overline{\text{CTS}}$ is set to 1, if transmission is in progress, the line goes to the mark state after transmission of one frame. When $\overline{\text{CTS}}$ is set to 0, the next transmit data is output starting from the start bit.

Figure 14.6 shows an example of the operation when modem control is used.

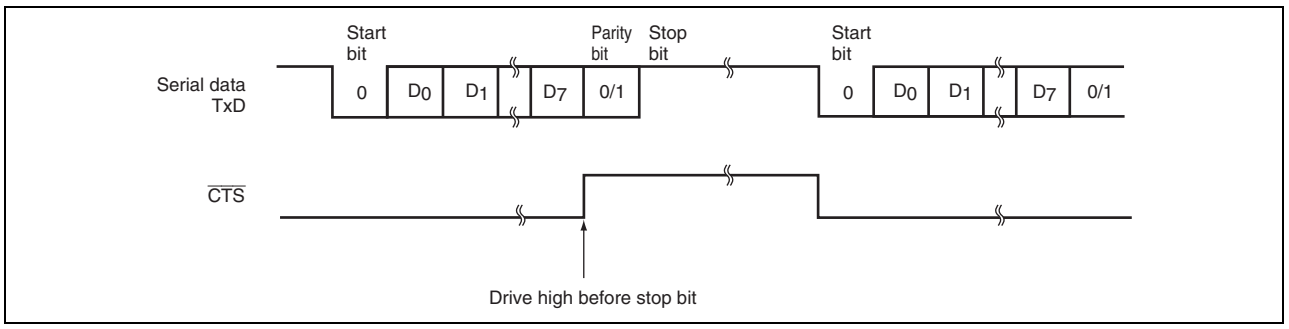

Figure 14.6 Example of Operation Using Modem Control ($\overline{\text{CTS}}$)

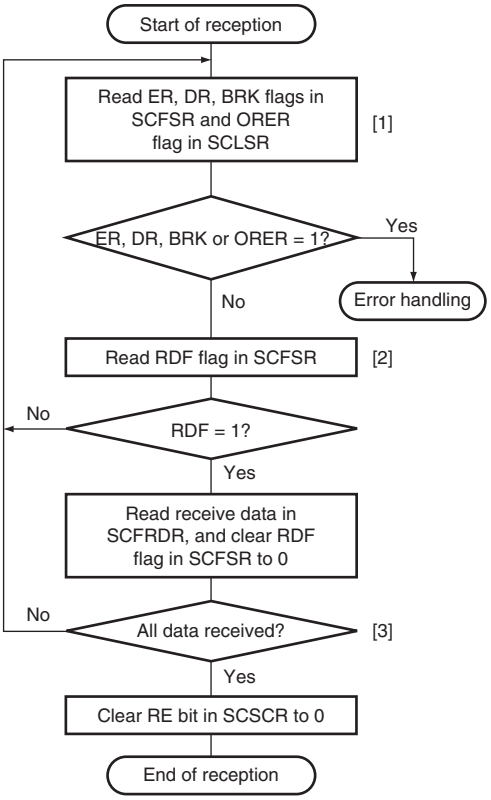
- Receiving Serial Data (Asynchronous Mode)

  Figure 14.7 and Figure 14.8 show sample flowcharts for serial reception.

  Use the following procedure for serial data reception after enabling reception.



[1] Receive error handling and break detection:

Read the DR, ER, and BRK flags in SCFSR, and the ORER flag in SCLSR, to identify any error, perform the appropriate error handling, then clear the DR, ER, BRK, and ORER flags to 0. In the case of a framing error, a break can also be detected by reading the value of the RxD pin.

[2] Status check and receive data read:

Read SCFSR and check that RDF flag = 1, then read the receive data in SCFRDR, read 1 from the RDF flag, and then clear the RDF flag to 0. The transition of the RDF flag from 0 to 1 can also be identified by a receive FIFO data full interrupt (RXI).

[3] Serial reception continuation procedure:

To continue serial reception, read at least the receive trigger set number of receive data bytes from SCFRDR, read 1 from the RDF flag, then clear the RDF flag to 0. The number of receive data bytes in SCFRDR can be ascertained by reading lower 8 bits of SCFDR.

Figure 14.7 Sample Flowchart for Receiving Serial Data (1)

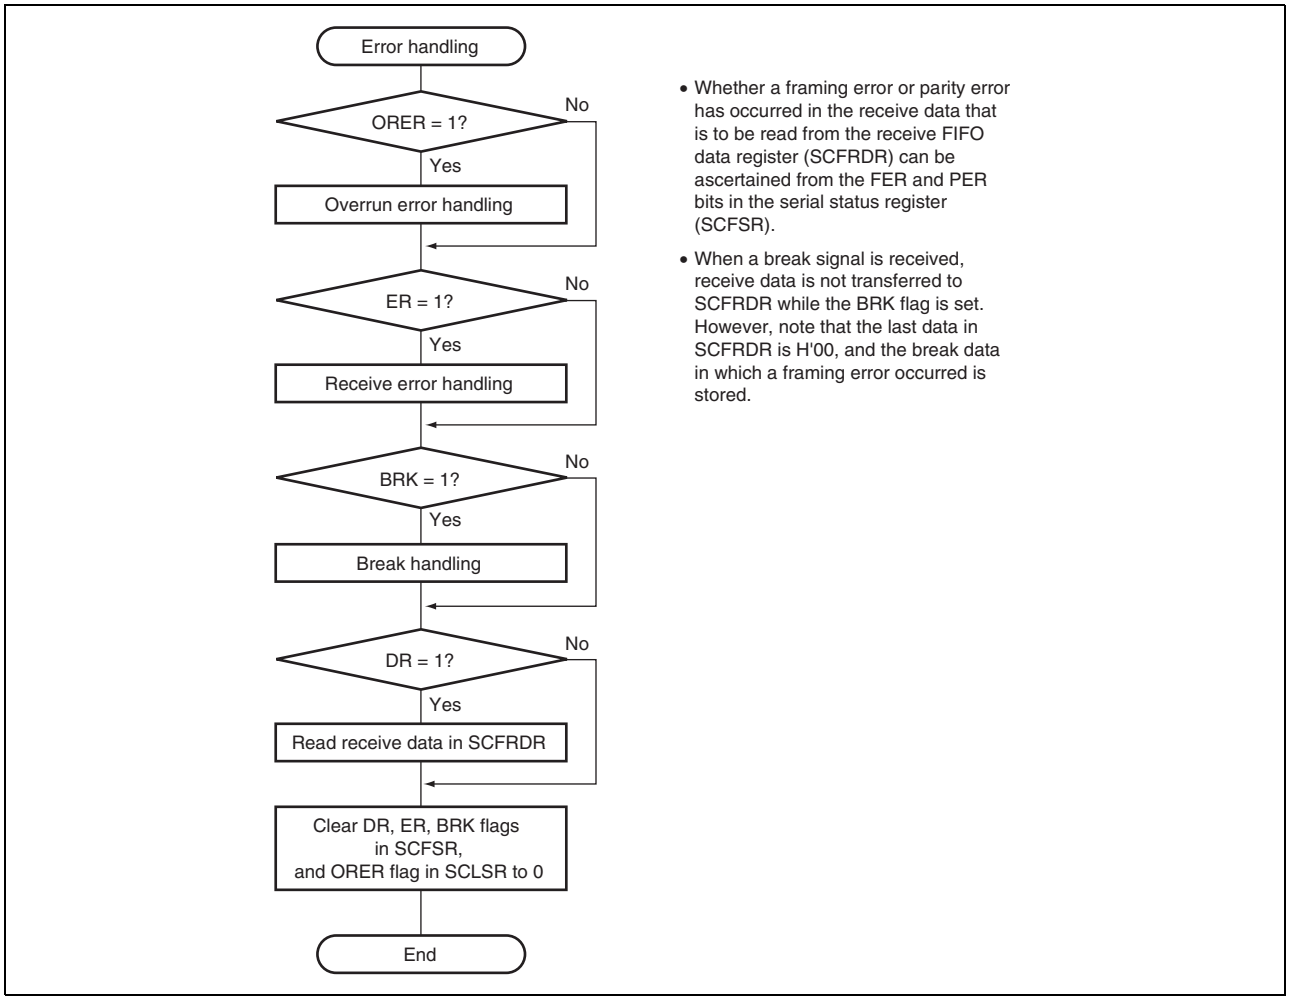


Figure 14.8 Sample Flowchart for Receiving Serial Data (2)

In serial reception, this module operates as described below.

1. The transmission line is monitored, and if a 0 start bit is detected, internal synchronization is performed and reception is started.

2. The received data is stored in SCRSR in LSB-to-MSB order.

3. The parity bit and stop bit are received.
   After receiving these bits, this module carries out the following checks.

   A. Stop bit check: Checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
   B. Checks whether receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
   C. Overrun check: Checks that the ORER flag is 0, indicating that the overrun error has not occurred.
   D. Break check: Checks that the BRK flag is 0, indicating that the break state is not set.

   If all the above checks are passed, the receive data is stored in SCFRDR.

   Note: When a parity error or a framing error occurs, reception is not suspended.

4. If the RIE bit in SCSCR is set to 1 when the RDF or DR flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the BRK or ORER flag changes to 1, a break reception interrupt (BRI) request is generated.

Figure 14.9 shows an example of the operation for reception in asynchronous mode.

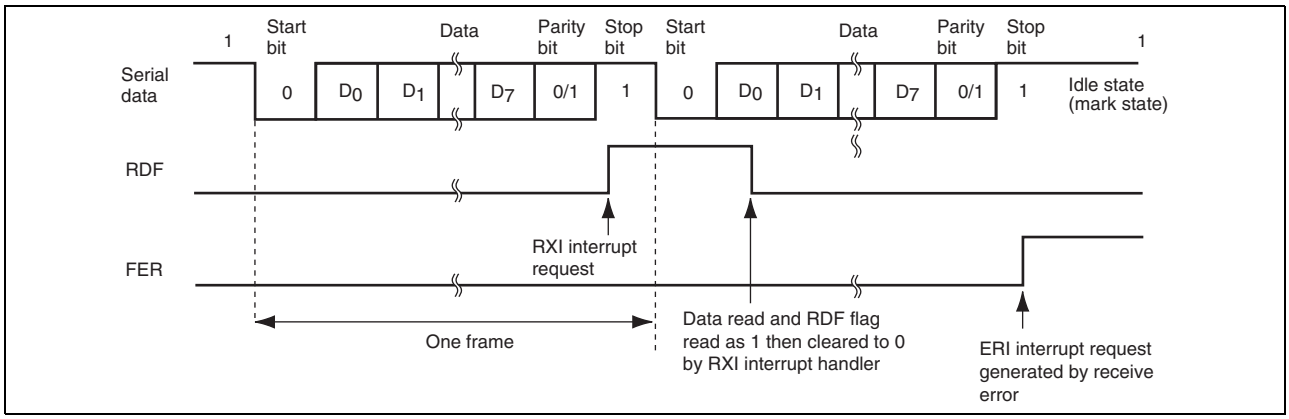

Figure 14.9 Example of Receive Operation(8-Bit Data, Parity, 1 Stop Bit)

5. When modem control is enabled in channels 0, 1, and 2, the $\overline{\text{RTS}}$ signal is output when SCFRDR is empty. When $\overline{\text{RTS}}$ is 0, reception is possible. When $\overline{\text{RTS}}$ is 1, this indicates that the quantity of data stored in SCFRDR has become equal to or greater than the number set for the RTS output active trigger.

Figure 14.10 shows an example of the operation when modem control is used.

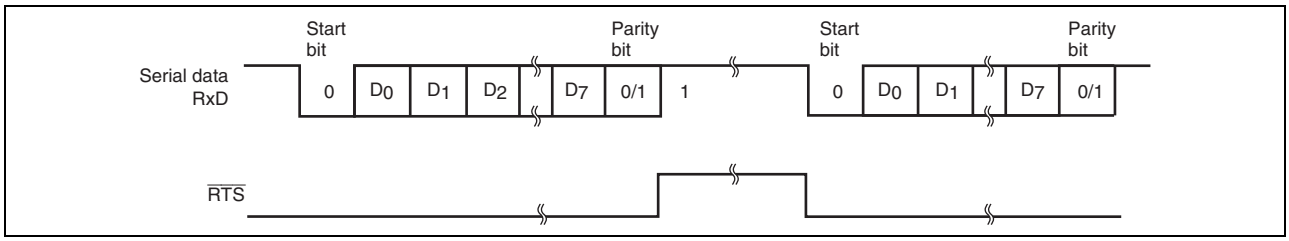

Figure 14.10 Example of Operation Using Modem Control ($\overline{\text{RTS}}$)

14.4.3 Operation in Clock Synchronous Mode

In clock synchronous mode, data is transmitted and received in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The transmitter and receiver in this module are independent, so full-duplex communication is possible while sharing the same clock. The transmitter and receiver are also 16-stage FIFO buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 14.11 shows the general format in clock synchronous serial communication.

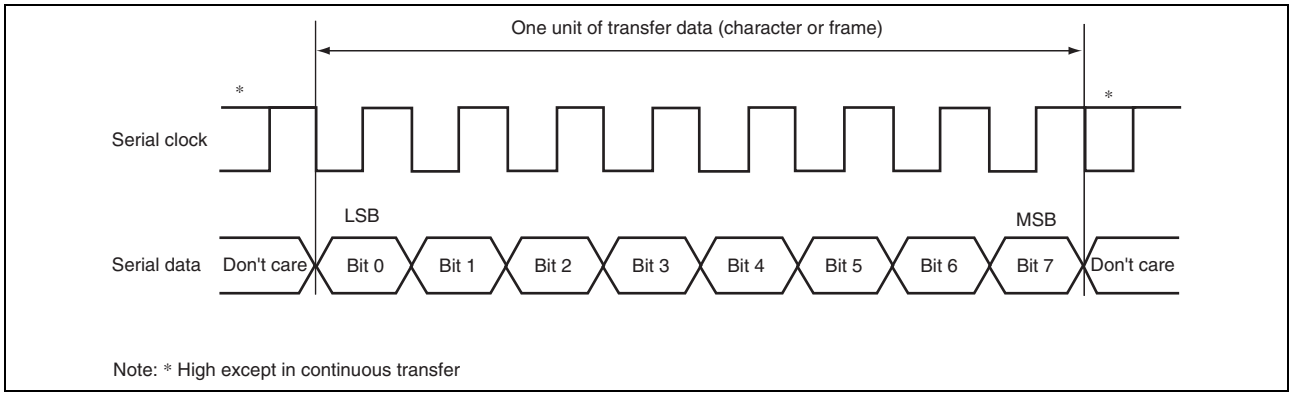

Figure 14.11 Data Format in Clock Synchronous Communication

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data is guaranteed valid at the rising edge of the serial clock.

In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB.

In clock synchronous mode, data is received in synchronization with the rising edge of the synchronous clock.

(1) Transmit/Receive Formats

The data length is fixed at eight bits. No parity bit can be added.

(2) Clock

An internal clock generated by the on-chip baud rate generator or an external synchronous clock input from the SCK pin can be selected by setting the C/$\overline{A}$ bit in SCSMR and the CKE[1:0] bits in SCSCR,.

When this module operates on an internal clock, it outputs the synchronous clock signal at the SCK pin. Eight clock pulses are output per one character transmission or reception. When transmission or reception is not performed, the clock signal remains in the high state. When only receiving is performed with the internal clock selected, the clock signal pulses are output while the RE bit of SCSCR is 1 and the number of data in receive FIFO is more than the receive FIFO data trigger number.

(3) Transmitting and Receiving Data

- Initialization (Clock Synchronous Mode)
  Before transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in the serial control register (SCSCR), and then initialize this module following the procedure described below.

  Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDF, PER, FER, and ORER flags and receive data register (SCRDR), which retain their previous contents.

Figure 14.12 shows a sample flowchart for initialization.

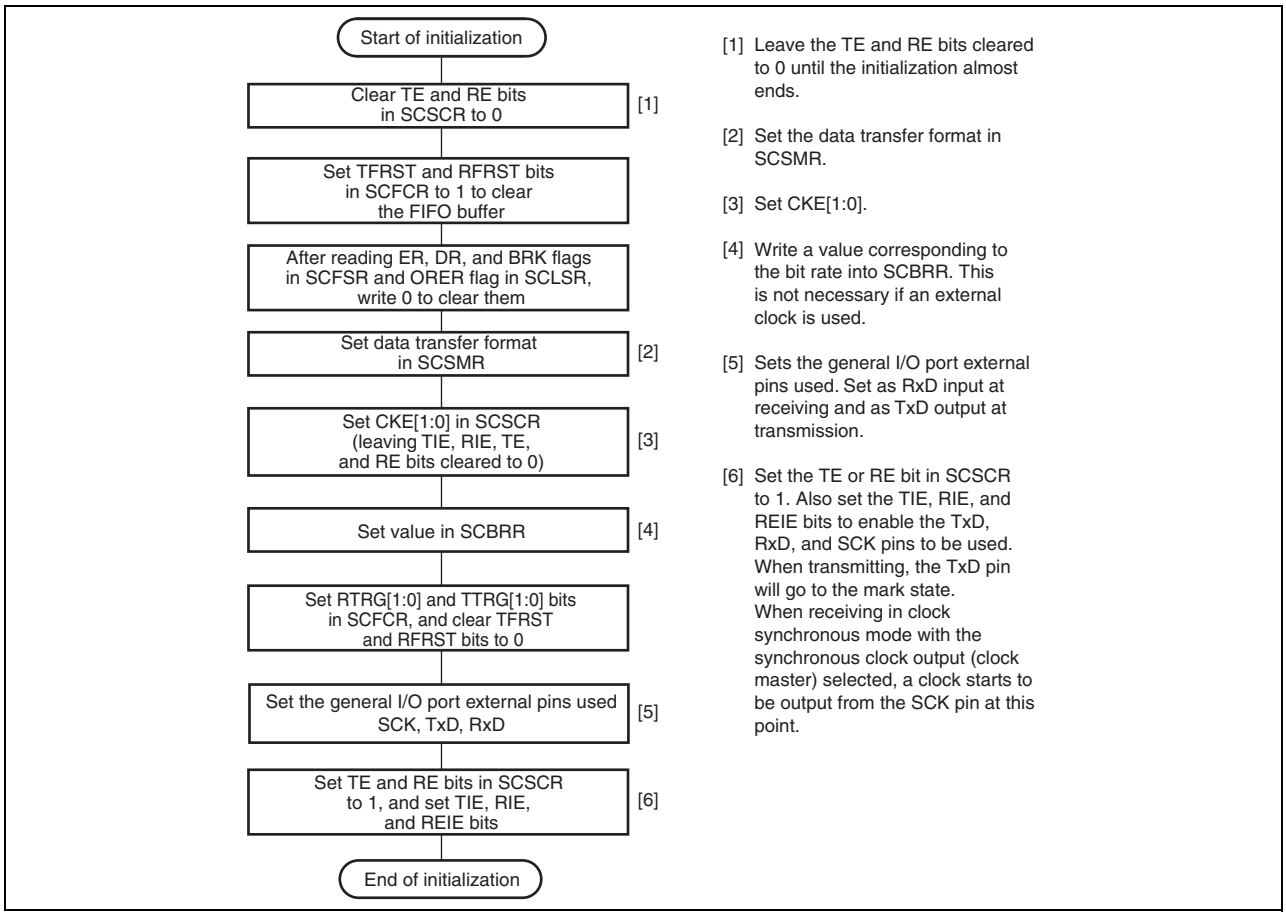

Figure 14.12 Sample Flowchart for Initialization

- Transmitting Serial Data (Clock Synchronous Mode)

  Figure 14.13 shows a sample flowchart for transmitting serial data.

  Use the following procedure for serial data transmission after enabling transmit operation.

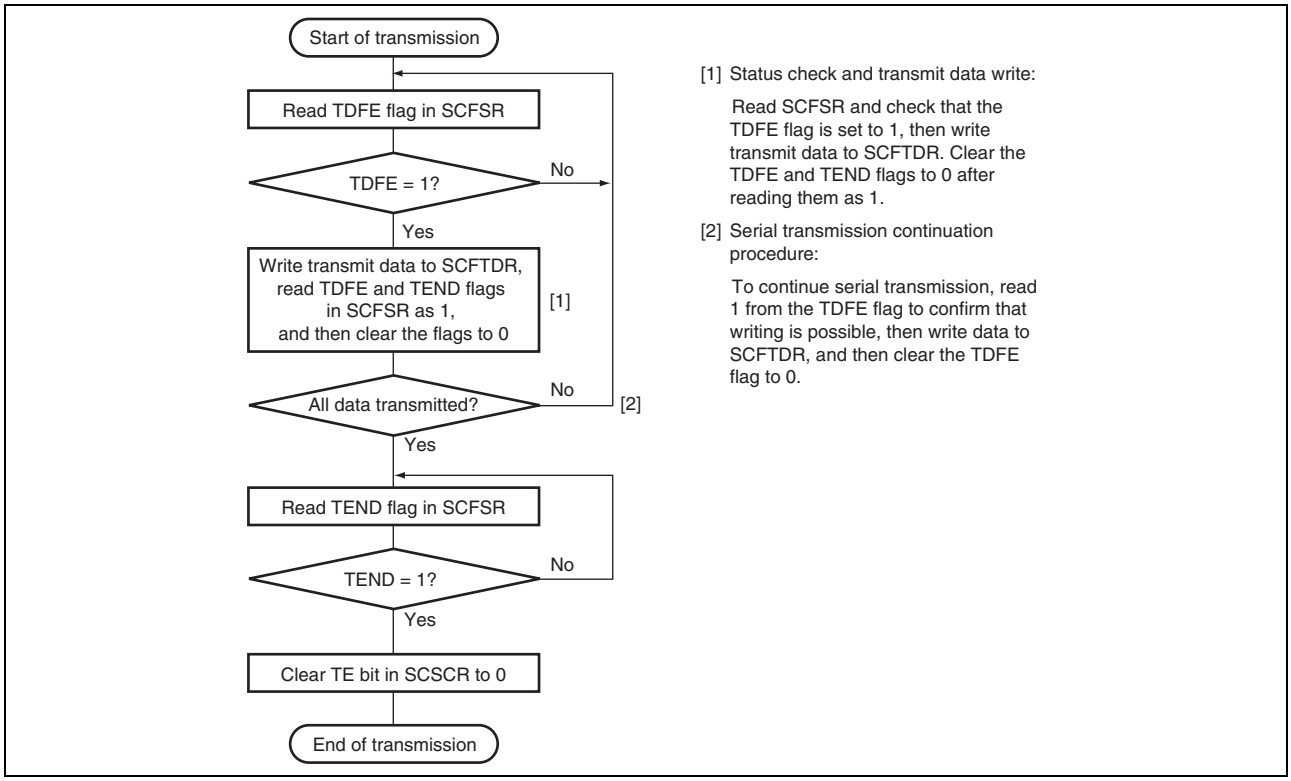

Figure 14.13 Sample Flowchart for Transmitting Serial Data

In serial transmission, this module operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the data is transferred from SCFTDR to the transmit shift register (SCTSR). Confirm that the TDFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of transmit data bytes that can be written is (16 – transmit trigger setting).

2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSCR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.
   If clock output mode is selected, eight synchronous clock pulses are output. If an external clock source is selected, data is output in synchronization with the input clock. Data is output from the TxD pin in order from the LSB (bit 0) to the MSB (bit 7).

3. The SCFTDR transmit data is checked at the timing for sending the MSB (bit 7). If data is present, the data is transferred from SCFTDR to SCTSR, and then serial transmission of the next frame is started. If there is no data, the TxD pin holds the state after the TEND flag in SCFSR is set to 1 and the MSB (bit 7) is sent.

4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 14.14 shows an example of transmit operation.

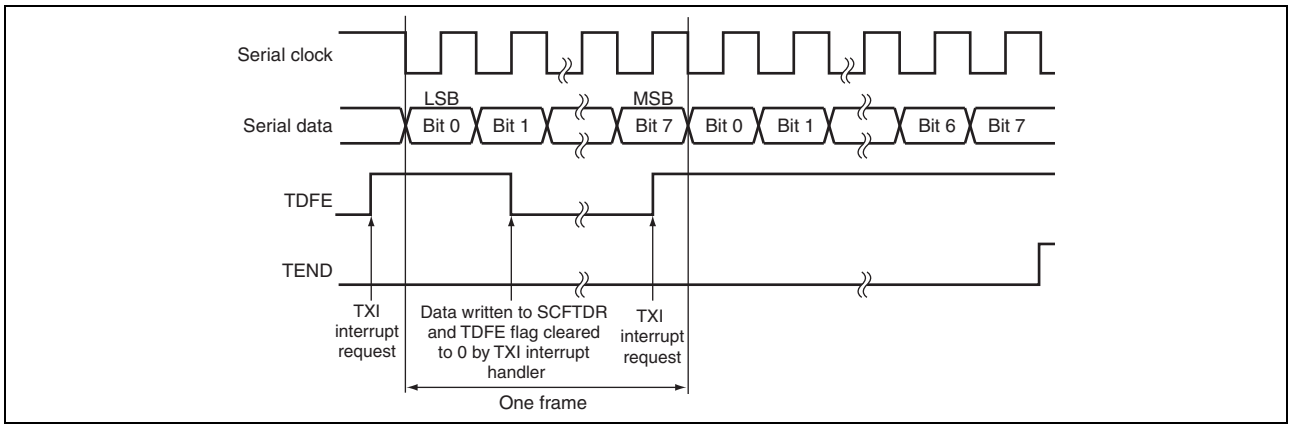

Figure 14.14 Example of Transmit Operation

- Receiving Serial Data (Clock Synchronous Mode)

  Figure 14.15 and Figure 14.16 show sample flowcharts for receiving serial data. Use the following procedure for serial data reception after enabling receive operation. When switching from asynchronous mode to clock synchronous mode without initialization, make sure that ORER, PER, and FER are cleared to 0.

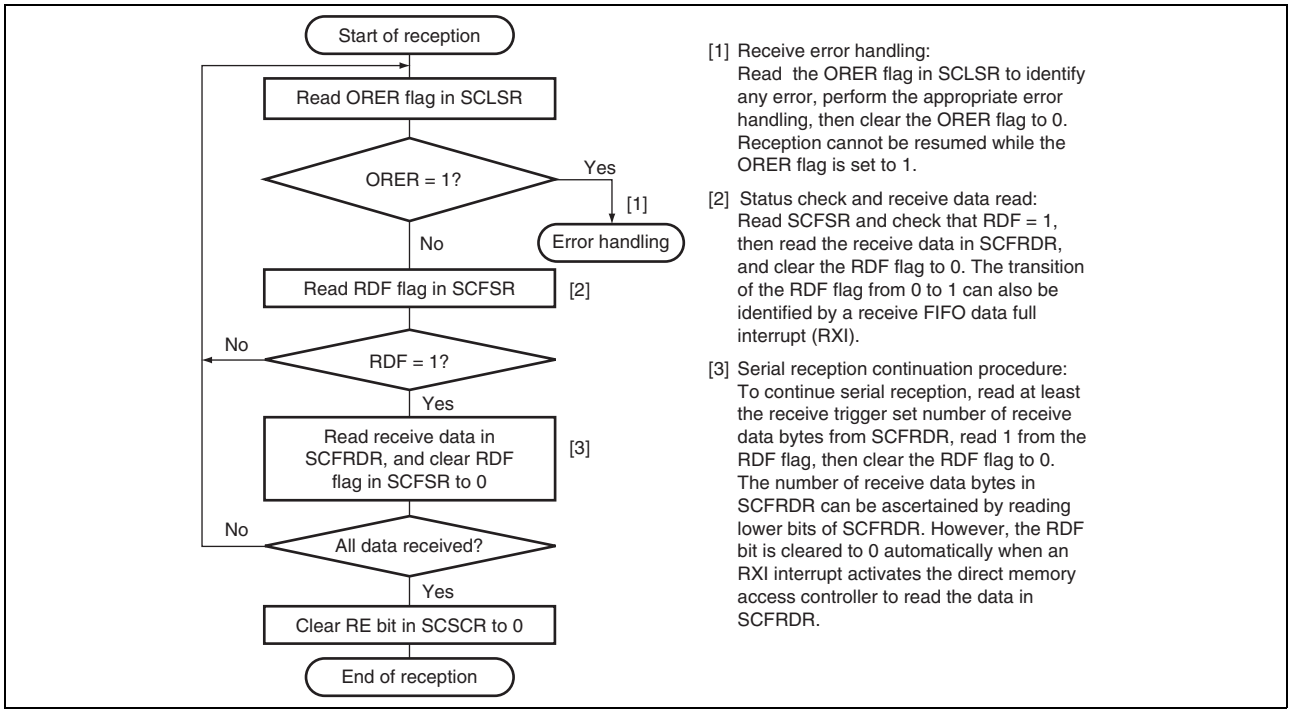

Figure 14.15 Sample Flowchart for Receiving Serial Data (1)

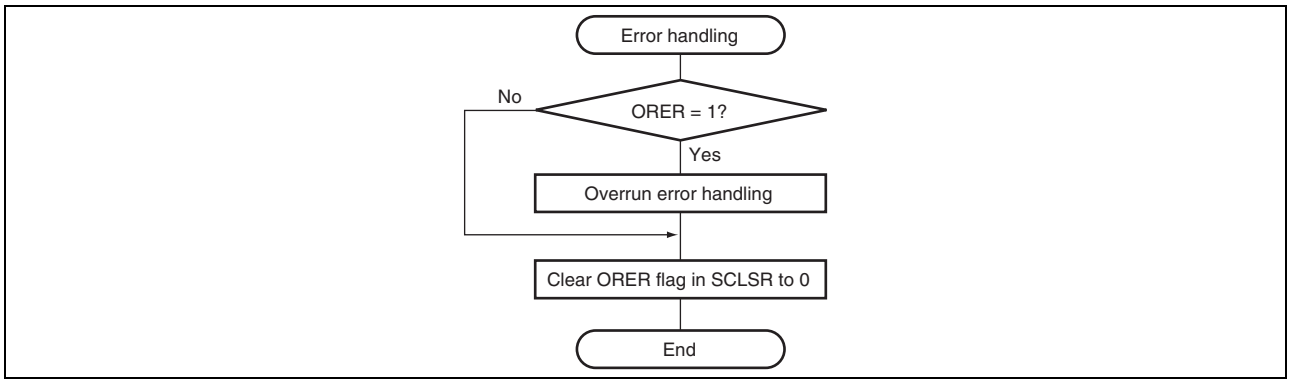

Figure 14.16 Sample Flowchart for Receiving Serial Data (2)

In serial reception, this module operates as described below.

1. Reception is started in synchronization with synchronous clock input or output.

2. Receive data is shifted into SCRSR in order from the LSB to the MSB. After the data reception, whether the receive data can be loaded from SCRSR into SCFRDR or not is checked. If this check is passed, the RDF flag is set to 1 and the received data is stored in SCFRDR. If the check is not passed (overrun error is detected), further reception is prevented.

3. After setting RDF to 1, if the receive interrupt enable bit (RIE) is set to 1 in SCSCR, a receive FIFO data full interrupt (RXI) request is generated. If the ORER bit is set to 1 and the receive interrupt enable bit (RIE) or the receive error interrupt enable bit (REIE) in SCSCR is also set to 1, a break interrupt (BRI) request is generated.

Figure 14.17 shows an example of receive operation.

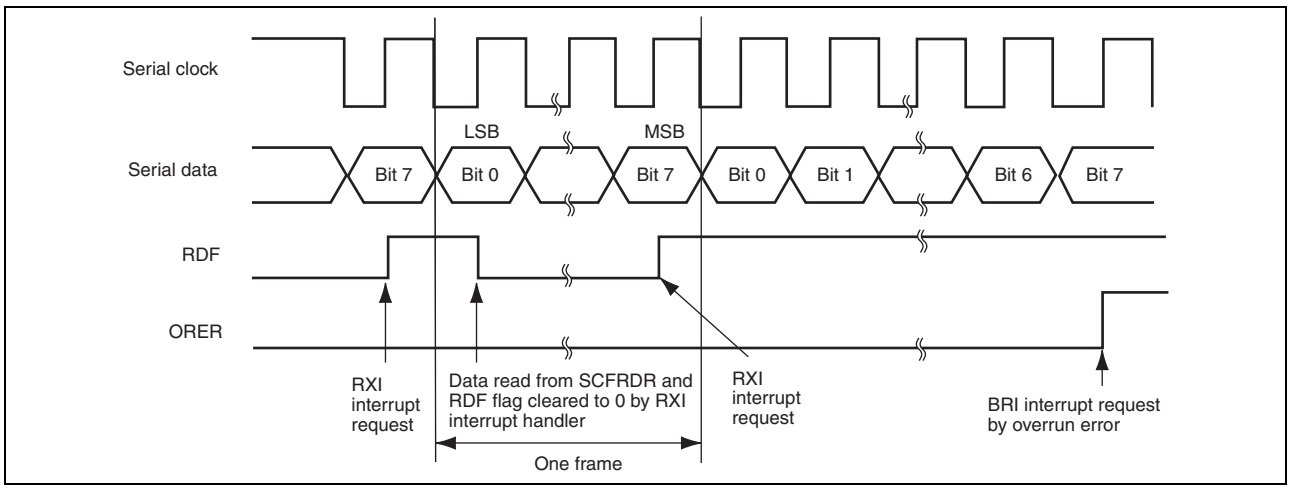

Figure 14.17 Example of Receive Operation

- Transmitting and Receiving Serial Data Simultaneously (Clock Synchronous Mode)

  Figure 14.18 shows a sample flowchart for transmitting and receiving serial data simultaneously.
  Use the following procedure for the simultaneous transmission/reception of serial data, after enabling transmit/receive operation.

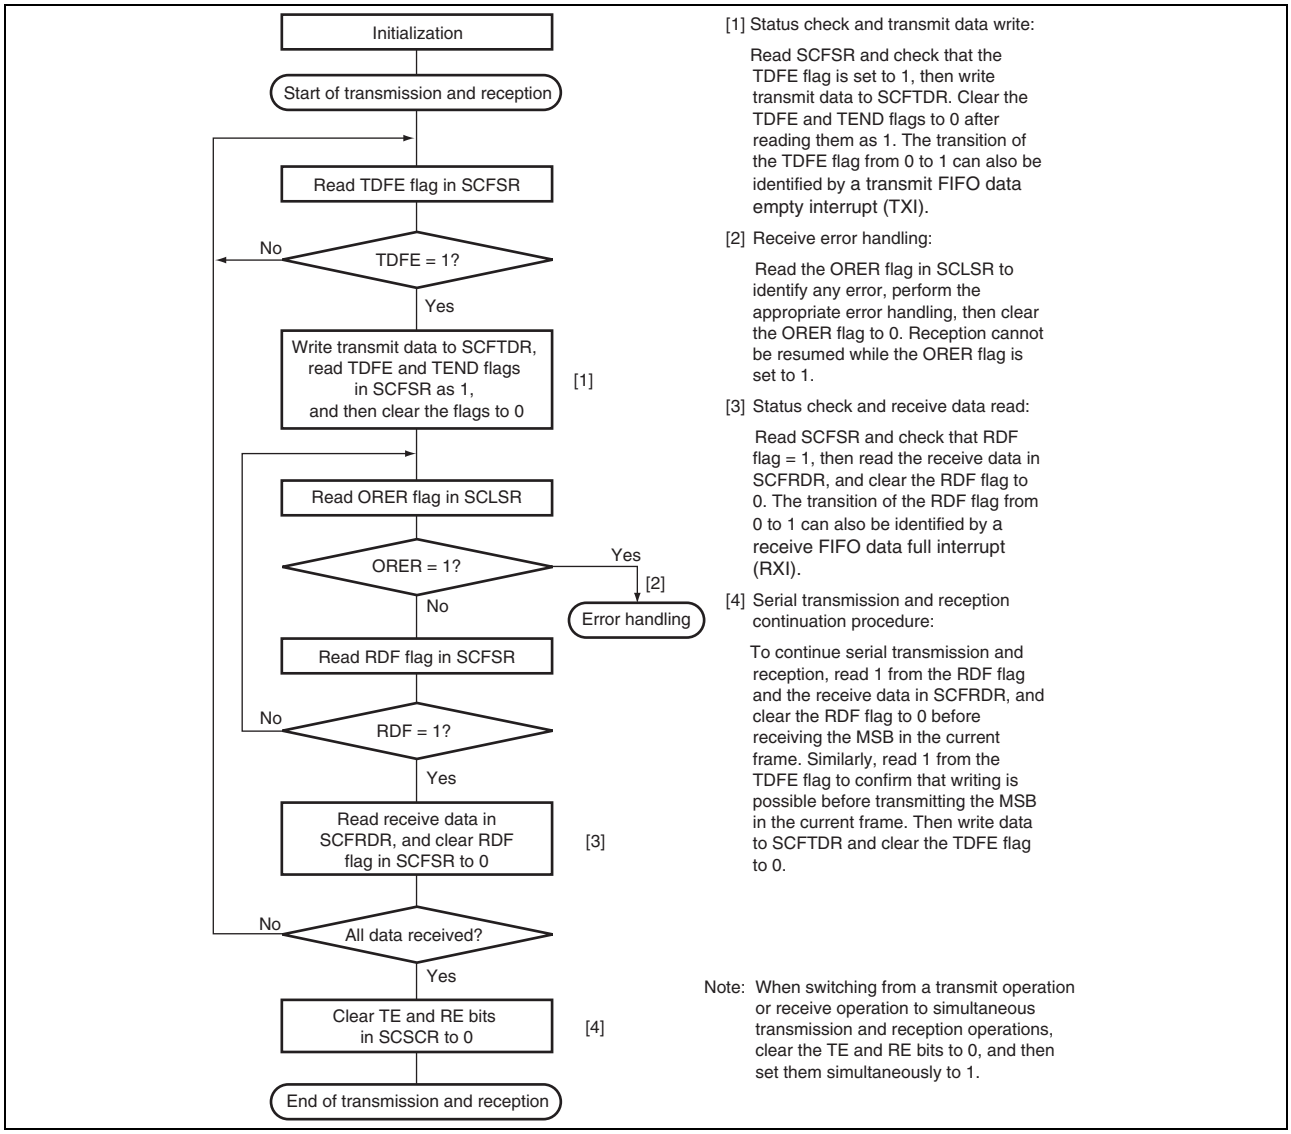

Figure 14.18 Sample Flowchart for Transmitting/Receiving Serial Data

14.5 Interrupts

This module has four interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive FIFO data full (RXI), and break (BRI).

Table 14.12 shows the interrupt sources and their order of priority. The interrupt sources are enabled or disabled by means of the TIE, RIE, and REIE bits in SCSCR. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When a TXI request is enabled by the TIE bit and the TDFE flag in the serial status register (SCFSR) is set to 1, a TXI interrupt request is generated. The direct memory access controller can be activated and data transfer performed by this TXI interrupt request. At this time, an interrupt request is not sent to the CPU.

When an RXI request is enabled by the RIE bit and the RDF flag or the DR flag in SCFSR is set to 1, an RXI interrupt request is generated. The direct memory access controller can be activated and data transfer performed by this RXI interrupt request. At this time, an interrupt request is not sent to the CPU. The RXI interrupt request caused by the DR flag is generated only in asynchronous mode.

When the RIE bit is set to 0 and the REIE bit is set to 1, this module requests only an ERI or a BRI interrupt without requesting an RXI interrupt.

The TXI indicates that transmit data can be written, and the RXI indicates that there is receive data in SCFRDR.

Table 14.12 Interrupt Sources

Interrupt Source	Description	Direct Memory Access Controller Activation	Priority on Reset Release
BRI	Interrupt initiated by break (BRK) or overrun error (ORER)	Not possible	High
ERI	Interrupt initiated by receive error (ER)	Not possible	↕
RXI	Interrupt initiated by receive FIFO data full (RDF) or data ready (DR)	Possible	
TXI	Interrupt initiated by transmit FIFO data empty (TDFE)	Possible	Low

14.6 Usage Notes

Note the following when using this module.

14.6.1 SCFTDR Writing and TDFE Flag

The TDFE flag in the serial status register (SCFSR) is set when the number of transmit data bytes written in the transmit FIFO data register (SCFTDR) has fallen below the transmit trigger number set by bits TTRG[1:0] in the FIFO control register (SCFCR). After the TDFE flag is set, transmit data up to the number of empty bytes in SCFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. The TDFE flag should therefore be cleared to 0 after being read as 1 when SCFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCFTDR can be found from the upper 8 bits of the FIFO data count register (SCFDR).

14.6.2 SCFRDR Reading and RDF Flag

The RDF flag in the serial status register (SCFSR) is set when the number of receive data bytes in the receive FIFO data register (SCFRDR) has become equal to or greater than the receive trigger number set by bits RTRG[1:0] in the FIFO control register (SCFCR). After RDF flag is set, receive data equivalent to the trigger number can be read from SCFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCFRDR exceeds the trigger number, the RDF flag will be set to 1 again after being read as 1 and then cleared to 0. The RDF flag should therefore be cleared to 0 after being read as 1 after reading the number of the received data in the receive FIFO data register (SCFRDR) which is less than the trigger number.

The number of receive data bytes in SCFRDR can be found from the lower 8 bits of the FIFO data count register (SCFDR).

14.6.3 Restriction on Direct Memory Controller Usage

When the direct memory access controller writes data to SCFTDR due to a TXI interrupt request, the state of the TEND flag becomes undefined. Therefore, the TEND flag should not be used as the transfer end flag in such a case.

14.6.4 Break Detection and Processing

Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state the input from the RxD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

Note that, although transfer of receive data to SCFRDR is halted in the break state, the receive operation is continued.

14.6.5 Sending a Break Signal

The I/O condition and level of the TxD pin are determined by the SPB2IO and SPB2DT bits in the serial port register (SCSPTR). This feature can be used to send a break signal.

Until TE bit is set to 1 (enabling transmission) after initializing, the TxD pin does not work. During the period, mark status is performed by the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (high level output).

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (designating low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TxD pin.

14.6.6 Receive Data Sampling Timing and Receive Margin (Asynchronous Mode)

This module operates on a base clock with a frequency 16 or 8 times the bit rate. In reception, the falling edge of the start bit is sampled at the base clock to perform synchronization internally. Receive data is latched at the rising edge of the eighth or fourth base clock pulse. When this module operates on a base clock with a frequency 16 times the bit rate, the receive data is sampled at the timing shown in Figure 14.19.

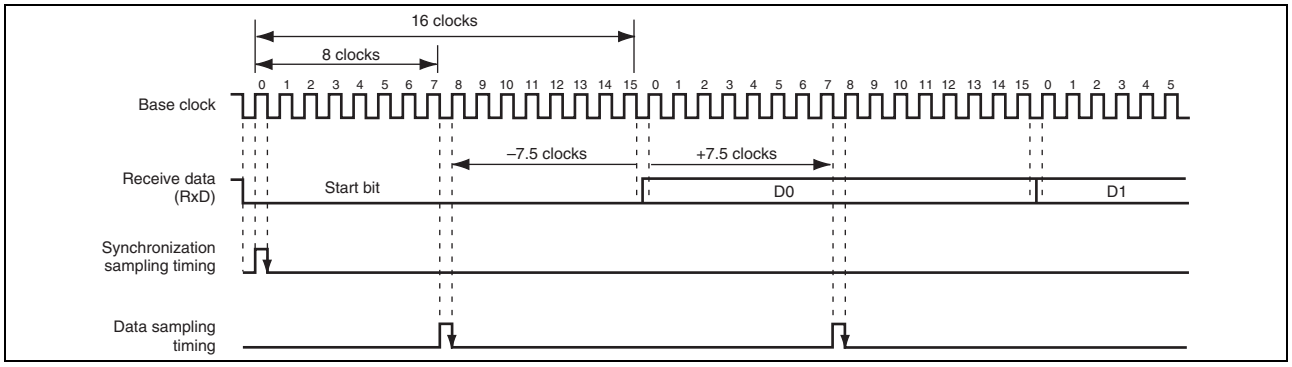

Figure 14.19 Receive Data Sampling Timing in Asynchronous Mode (Operation on a Base Clock with a Frequency 16 Times the Bit Rate)

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

Equation 1:

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\,F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ \%$$

Where: M: Receive margin (%)
N: Ratio of clock frequency to bit rate (N = 16 or 8)
D: Clock duty (D = 0 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute deviation of clock frequency

From equation 1, if F = 0, D = 0.5 and N = 16, the receive margin is 46.875%, as given by equation 2.

Equation 2:

When D = 0.5 and F = 0:

$M = (0.5 - 1/(2 \times 16)) \times 100\%$

$= 46.875\%$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

14.6.7 Selection of Base Clock in Asynchronous Mode

In this LSI, when asynchronous mode is selected, the base clock frequency within a bit period can be set to the frequency 16 or 8 times the bit rate by setting the ABCS bit in SCEMR.

Note that, however, if the base clock frequency 8 times the bit rate is used, receive margin is decreased as calculated using equation 1 in section 14.6.6, Receive Data Sampling Timing and Receive Margin (Asynchronous Mode).

If the desired bit rate can be set simply by setting SCBRR and the CKS[1:0] bits in SCSMR, it is recommended to use the base clock frequency within a bit period 16 times the bit rate (by setting the ABCS bit in SCEMR to 0). If an internal clock is selected as a clock source and the SCK pin is not used, the bit rate can be increased without decreasing receive margin by selecting double-speed mode for the baud rate generator (setting the BGDM bit in SCEMR to 1).

15. Serial Communications Interface

This LSI has two independent serial communications interface (SCI) channels.
The SCI can handle both asynchronous and clock synchronous serial communications.
Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA).
As an extended function in asynchronous communications mode, the SCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards).

15.1 Overview

Table 15.1 lists the specifications of the SCI module.
Figure 15.1 is a block diagram of the SCI module.

Table 15.1 Specifications of SCI

Item		Specifications
Serial communications mode		• Asynchronous operation • Clock synchronous operation • Smart card interface
Transfer speed		Bit rate specifiable with on-chip baud rate generator.
Full-duplex communications		Transmitter: Enables continuous transmission by double-buffering. Receiver: Enables continuous reception by double-buffering.
I/O pins		See Table 15.2.
Data transfer		Selectable as LSB-first or MSB-first transfer
Interrupt sources		Transmit-end, transmit-data-empty, receive-data-full, and receive error
Power consumption reduction function		Module-standby state can be set for each channel.
Asynchronous mode	Data length	7 or 8 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even, odd, or none
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn and RTSn pins can be used in transfer control.
	Break detection	Break can be detected by reading RXDn pin level directly in case of a framing error
	Clock source	Selectable from internal or external clock
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun errors
	Hardware flow control	CTSn and RTSn pins can be used in transfer control.
Smart card interface mode	Error processing	An error signal can be automatically transmitted on detection of a parity error during reception
		Data can be automatically re-transmitted on receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.

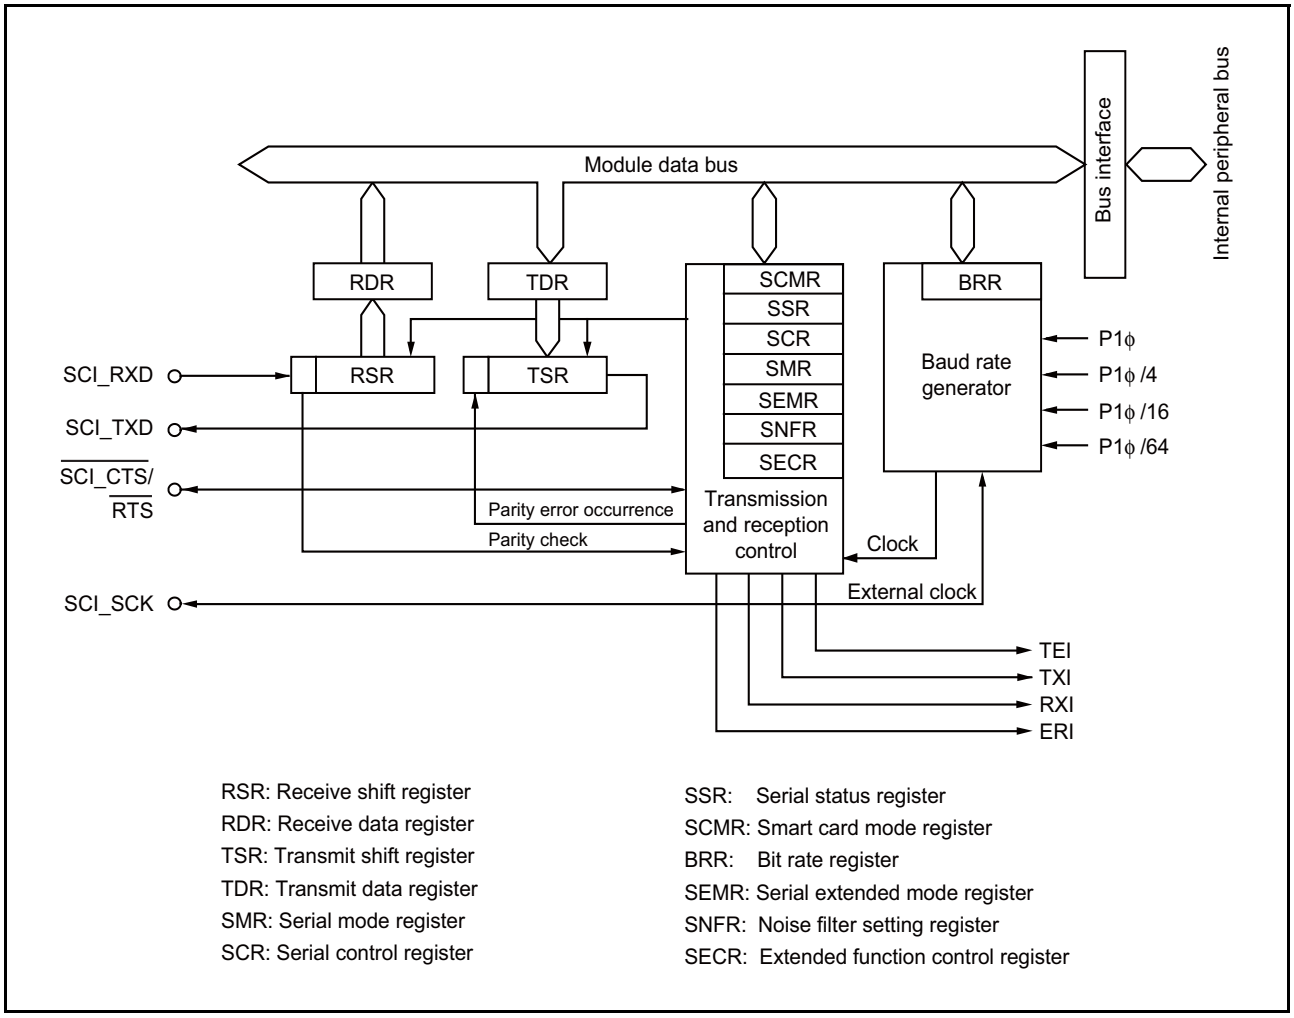

Figure 15.1 Block Diagram of SCI

Table 15.2 lists the pin configuration of the SCIs.

Table 15.2 Input and Output Pins of the SCIs

Channel	Pin Name	I/O	Function
SCI0	SCI_SCK0	I/O	SCI0 clock input/output
	SCI_RXD0	Input	SCI0 receive data input
	SCI_TXD0	Output	SCI0 transmit data output
	$\overline{\text{SCI\_CTS0}}$/$\overline{\text{RTS0}}$	I/O	SCI0 transfer start control input/output
SCI1	SCI_SCK1	I/O	SCI1 clock input/output
	SCI_RXD1	Input	SCI1 receive data input
	SCI_TXD1	Output	SCI1 transmit data output
	$\overline{\text{SCI\_CTS1}}$/$\overline{\text{RTS1}}$	I/O	SCI1 transfer start control input/output

Note: • These pins are referred to as SCKn, RXDn, TXDn, RTSn#, and CTSn# in the text in this section.

15.2 Register Descriptions

Table 15.3 is a list of registers.

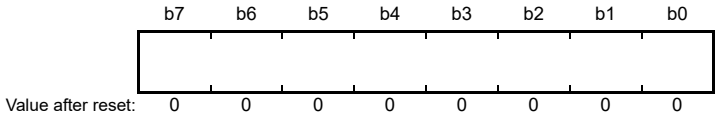
Table 15.3 List of Registers

Channel	Register Name	Symbol	Value after Reset	Address	Access size
0	Serial mode register 0	SMR0	H'00	H'E800B000	8
	Bit rate register 0	BRR0	H'FF	H'E800B001	8
	Serial control register 0	SCR0	H'00	H'E800B002	8
	Transmit data register 0	TDR0	H'FF	H'E800B003	8
	Serial status register 0	SSR0	H'84	H'E800B004	8
	Receive data register 0	RDR0	H'00	H'E800B005	8
	Smart card mode register 0	SCMR0	H'F2	H'E800B006	8
	Serial extended mode register 0	SEMR0	H'00	H'E800B007	8
	Noise filter setting register 0	SNFR0	H'00	H'E800B008	8
	Extended function control register 0	SECR0	H'00	H'E800B00D	8
1	Serial mode register 1	SMR1	H'00	H'E800B800	8
	Bit rate register 1	BRR1	H'FF	H'E800B801	8
	Serial control register 1	SCR1	H'00	H'E800B802	8
	Transmit data register 1	TDR1	H'FF	H'E800B803	8
	Serial status register 1	SSR1	H'84	H'E800B804	8
	Receive data register 1	RDR1	H'00	H'E800B805	8
	Smart card mode register 1	SCMR1	H'F2	H'E800B806	8
	Serial extended mode register 1	SEMR1	H'00	H'E800B807	8
	Noise filter setting register 1	SNFR1	H'00	H'E800B808	8
	Extended function control register 1	SECR1	H'00	H'E800B80D	8

15.2.1 Receive Shift Register (RSR)

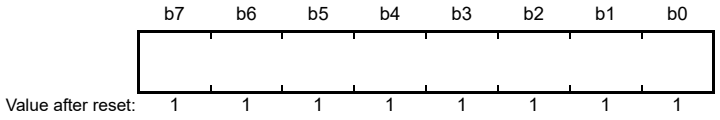
RSR is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data. When one frame of data has been received, it is transferred to RDR automatically.
RSR cannot be directly accessed by the CPU.

15.2.2 Receive Data Register (RDR)



RDR is an 8-bit register that stores receive data.
When the SCI has received one frame of serial data, it transfers the received serial data from RSR to RDR where it is stored. This allows RSR to receive the next data.
Since RSR and RDR function as a double buffer in this way, continuous receive operations can be performed.
Only read RDR once after each instance of the receive data full interrupt (RXI). Note that if next one frame of data is received before reading receive data from RDR, an overrun error occurs.
RDR cannot be written to by the CPU.

15.2.3 Transmit Data Register (TDR)



TDR is an 8-bit register that stores transmit data.
When the SCI detects that TSR is empty, it transfers the transmit data written in TDR to TSR and starts transmission.
The double-buffered structures of TDR and TSR enable continuous serial transmission. If the next transmit data has already been written to TDR when one frame of data is transmitted, the SCI transfers the written data to TSR to continue transmission.
The CPU is able to read from or write to TDR at any time. Only write data for transmission to TDR once after each instance of the transmit data empty interrupt (TXI).

15.2.4 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data.
To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, and then sends the data to the TXDn pin.
TSR cannot be directly accessed by the CPU.

15.2.5 Serial Mode Register (SMR)

Note: • Some bits in SMR have different functions in serial communications interface mode and smart card interface mode.

(1) Serial Communications Interface Mode (SMIF in SCMR = 0)

	b7	b6	b5	b4	b3	b2	b1	b0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: P1ϕ clock (n = 0)*1 0 1: P1ϕ/4 clock (n = 1)*1 1 0: P1ϕ/16 clock (n = 2)*1 1 1: P1ϕ/64 clock (n = 3)*1	R/W*4
b2	MP	Multi-Processor Mode	(Valid only in asynchronous mode) 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W*4
b3	STOP	Stop Bit Length	(Valid only in asynchronous mode) 0: 1 stop bit 1: 2 stop bits	R/W*4
b4	PM	Parity Mode	(Valid only when the PE bit is 1 in asynchronous mode) 0: Selects even parity 1: Selects odd parity	R/W*4
b5	PE	Parity Enable	(Valid only in asynchronous mode) • When transmitting 0: Parity bit addition is not performed 1: The parity bit is added • When receiving 0: Parity bit checking is not performed 1: The parity bit is checked	R/W*4
b6	CHR	Character Length	(Valid only in asynchronous mode) 0: Selects 8 bits as the data length*2 1: Selects 7 bits as the data length*3	R/W*4
b7	CM	Communications Mode	0: Asynchronous mode 1: Clock synchronous mode	R/W*4

Note 1. n is the decimal notation of the value of n in BRR (see section 15.2.9, Bit Rate Register (BRR)).
Note 2. In clock synchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission.
Note 4. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.
For the relation between the settings of these bits and the baud rate, see section 15.2.9, Bit Rate Register (BRR).

MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

STOP Bit (Stop Bit Length)

Selects the stop bit length in transmission.
In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM Bit (Parity Mode)

Selects the parity mode (even or odd) for transmission and reception.
The setting of the PM bit is invalid in multi-processor mode.

PE Bit (Parity Enable)

When this bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception.
Irrespective of the setting of the PE bit, the parity bit is not added or checked in multi-processor format.

CHR Bit (Character Length)

Selects the data length for transmission and reception.
In clock synchronous mode, a fixed data length of 8 bits is used.

(2) Smart Card Interface Mode (SMIF in SCMR = 1)

	b7	b6	b5	b4	b3	b2	b1	b0
	GM	BLK	PE	PM	BCP[1:0]		CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: P1ϕ clock (n = 0)*1 0 1: P1ϕ/4 clock (n = 1)*1 1 0: P1ϕ/16 clock (n = 2)*1 1 1: P1ϕ/64 clock (n = 3)*1	R/W*3
b3, b2	BCP[1:0]	Base Clock Pulse	Selects the number of base clock cycles in combination with the BCP2 bit in SCMR. Setting values in BCP2 bit in SCMR and BCP[1:0] bits in SMR: BCP2 b3 b2 0 0 0: 93 clock cycles (S = 93)*2 0 0 1: 128 clock cycles (S = 128)*2 0 1 0: 186 clock cycles (S = 186)*2 0 1 1: 512 clock cycles (S = 512)*2 1 0 0: 32 clock cycles (S = 32)*2 (Initial value) 1 0 1: 64 clock cycles (S = 64)*2 1 1 0: 372 clock cycles (S = 372)*2 1 1 1: 256 clock cycles (S = 256)*2	R/W*3
b4	PM	Parity Mode	(Valid only when the PE bit is 1 in asynchronous mode) 0: Selects even parity 1: Selects odd parity	R/W*3
b5	PE	Parity Enable	When this bit is set to 1, a parity bit is added to data for transmission, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.	R/W*3
b6	BLK	Block Transfer Mode	0: Normal mode operation 1: Block transfer mode operation	R/W*3
b7	GM	GSM Mode	0: Normal mode operation 1: GSM mode operation	R/W*3

Note 1. n is the decimal notation of the value of n in BRR (see section 15.2.9, Bit Rate Register (BRR)).
Note 2. S is the value of S in BRR (see section 15.2.9, Bit Rate Register (BRR)).
Note 3. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.
For the relationship between the settings of these bits and the baud rate, see section 15.2.9, Bit Rate Register (BRR).

BCP[1:0] Bits (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.
Set these bits in combination with the BCP2 bit in SCMR.
For details, see section 15.6.4, Receive Data Sampling Timing and Reception Margin.

PM Bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd).
For details on the usage of this bit in smart card interface mode, see section 15.6.2, Data Format (Except in Block Transfer Mode).

PE Bit (Parity Enable)

Set the PE bit to 1.
The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK Bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.
For details, see section 15.6.3, Block Transfer Mode.

GM Bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.
In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, see section 15.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 15.6.8, Clock Output Control.

15.2.6 Serial Control Register (SCR)

Note: • Some bits in SCR have different functions in serial communications interface mode and smart card interface mode.

(1) Serial Communications Interface Mode (SMIF in SCMR = 0)

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	(Asynchronous mode) b1 b0 0 0: On-chip baud rate generator The SCKn pin functions as general-purpose I/O port. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock SEMR.ABCS bit is 0: The clock with a frequency 16 times the bit rate should be input from the SCKn pin. SEMR.ABCS bit is 1: The clock with a frequency eight times the bit rate should be input from the SCKn pin. (Clock synchronous mode) b1 b0 0 x: Internal clock The SCKn pin functions as the clock output pin. 1 x: External clock The SCKn pin functions as the clock input pin.	R/W*1
b2	TEIE	Transmit End Interrupt Enable	0: A TEI interrupt request is disabled 1: A TEI interrupt request is enabled	R/W
b3	MPIE	Multi-Processor Interrupt Enable	(Valid in asynchronous mode when SMR.MP = 1) 0: Normal reception 1: When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags ORER and FER in SSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and normal reception is resumed.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*2
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*2
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. A 1 can be written only when TE = 0 and RE = 0, while the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written in TE and RE. While the SMR.CM bit is 0, writing is enabled under any condition.

CKE[1:0] Bits (Clock Enable)

These bits select the clock source and SCKn pin function.

TEIE Bit (Transmit End Interrupt Enable)

Enables or disables a TEI interrupt request.
A TEI interrupt request is disabled by clearing the TEIE bit to 0.

MPIE Bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags ORER and FER in SSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, see section 15.4, Multi-Processor Communications Function.
When the receive data includes the MPB bit is SSR set to 0, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.
When the receive data includes the MPB bit set to 1, the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting the flags ORER and FER to 1 is enabled.
MPIE should be set to 0 if multi-processor communications function is not to be used.

RE Bit (Receive Enable)

Enables or disables serial reception.
When this bit is set to 1, serial reception is started by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Note that SMR should be set prior to setting the RE bit to 1 in order to designate the reception format.
Even if reception is halted by clearing the RE bit to 0, the ORER, FER, and PER flags in SSR are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.
When this bit is set to 1, serial transmission is started by writing transmit data to TDR. Note that SMR should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.
An RXI interrupt request is disabled by clearing the RIE bit to 0.
An ERI interrupt request can be cancelled by reading 1 from the ORER, FER, or PER flag in SSR and then clearing the flag to 0, or clearing the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables notification of a TXI interrupt request.
Notification of a TXI interrupt request is disabled by clearing the TIE bit to 0.

(2) Smart Card Interface Mode (SMIF in SCMR = 1)

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• When GM in SMR = 0 b1 b0 0 0: Output disabled (The SCKn pin is available for use as an I/O port in accord with the general-purpose I/O port settings.) 0 1: Clock output 1 x: (Setting prohibited) • When GM in SMR = 1 b1 b0 0 0: Output fixed low x 1: Clock output 1 0: Output fixed high	R/W*1
b2	TEIE	Transmit End Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b3	MPIE	Multi-Processor Interrupt Enable	This bit should be 0 in smart card interface mode.	R/W
b4	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W*2
b5	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*2
b6	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b7	TIE	Transmit Interrupt Enable	0: A TXI interrupt request is disabled 1: A TXI interrupt request is enabled	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. A 1 can be written only when TE = 0 and RE = 0, while the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written in TE and RE. While the SMR.CM bit is 0, writing is enabled under any condition.

For details on interrupt requests, see section 15.8, Interrupt Sources.

CKE[1:0] Bits (Clock Enable)

These bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, see section 15.6.8, Clock Output Control.

TEIE Bit (Transmit End Interrupt Enable)

This bit should be 0 in smart card interface mode.

MPIE Bit (Multi-Processor Interrupt Enable)

This bit should be 0 in smart card interface mode.

RE Bit (Receive Enable)

Enables or disables serial reception.

When this bit is set to 1, serial reception is started by detecting the start bit. Note that SMR should be set prior to setting the RE bit to 1 in order to designate the reception format.

Even if reception is halted by clearing the RE bit to 0, the ORER, FER, and PER flags in SSR are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission is started by writing transmit data to TDR. Note that SMR should be set prior to setting the TE bit to 1 in order to designate the transmission format.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.

An RXI interrupt request is disabled by clearing the RIE bit to 0.

An ERI interrupt request can be cancelled by reading 1 from the ORER, FER, or PER flag in SSR and then clearing the flag to 0, or clearing the RIE bit to 0.

TIE Bit (Transmit Interrupt Enable)

Enables or disables notification of a TXI interrupt request.

Notification of a TXI interrupt request is disabled by clearing the TIE bit to 0.

15.2.7 Serial Status Register (SSR)

Note: • Some bits in SSR have different functions in serial communications interface mode and smart card interface mode.

(1) Serial Communications Interface Mode (SMIF in SCMR = 0)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	ORER	FER	PER	TEND	MPB	MPBT
Value after reset:	x	x	0	0	0	1	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	Sets the multi-processor bit for adding to the transmission frame 0: Data transmission cycles 1: ID transmission cycles	R/W
b1	MPB	Multi-Processor	Value of the multi-processor bit in the reception frame 0: Data transmission cycles 1: ID transmission cycles	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	FER	Framing Error Flag	0: No framing error occurred 1: A framing error has occurred	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b7, b6	—	Reserved	The read value is undefined. The write value should be 1.	R

Note 1. Only 0 can be written to this bit, to clear the flag.

MPB Bit (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the RE bit in SCR is 0.

TEND Flag (Transmission End Flag)

Indicates completion of transmission.

[Setting conditions]

- Clearing of the SCR.TE bit to 0 (disabling serial transmission operations)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- The TDR is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing condition]

- When data for transmission are written to the TDR while the SCR.TE is 1
  When the TEND flag is cleared in response to writing of data for transmission to the TDR, dummy read the TEND flag before return from interrupt exception processing for TEI interrupt requests when the latter are enabled.

PER Bit (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (after writing 0 to it, read the PER bit to check that it has actually been cleared to 0.)
  Even when the RE bit in SCR is cleared to 0 (which indicates that serial reception is disabled), the PER flag is not affected and retains its previous value.

FER Bit (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When the stop bit is 0
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after reading FER = 1 (after writing 0 to it, read the FER bit to check that it has actually been cleared to 0.)
  Even when the RE bit in SCR is cleared to 0, the FER flag is not affected and retains its previous value.

ORER Bit (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed. Note that, in clock synchronous mode, serial transmission also cannot continue.

[Clearing condition]

- When a 0 is written to ORER after reading ORER = 1 (after writing a 0 to it, read the ORER bit to check that it has actually been cleared to 0.)
  Even when the RE bit in SCR is cleared to 0, the ORER flag is not affected and retains its previous value.

(2) Smart Card Interface Mode (SMIF in SCMR = 1)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	x	x	0	0	0	1	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	This bit should be set to 0 in smart card interface mode.	R/W
b1	MPB	Multi-Processor	This bit is not used in smart card interface mode. It should be set to 0.	R
b2	TEND	Transmit End Flag	0: A character is being transmitted. 1: Character transfer has been completed.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: A parity error has occurred	R/(W) *1
b4	ERS	Error Signal Status Flag	0: Low error signal not responded 1: Low error signal responded	R/(W) *1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: An overrun error has occurred	R/(W) *1
b7, b6	—	Reserved	The read value is undefined. The write value should be 1.	R

Note 1. Only 0 can be written to this bit, to clear the flag.

MPBT Bit (Multi-Processor Bit Transfer)

This bit should be set to 0 in smart card interface mode.

MPB Bit (Multi-Processor)

This bit is not used in smart card interface mode. It should be set to 0.

TEND Flag (Transmission End Flag)

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When SCR.TE bit = 0 (disabling serial transmission operations)
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of one byte, the ERS flag is 0, and the TDR register is not updated
  The set timing is determined by register settings as listed below.
  When SMR.GM = 0 and SMR.BLK = 0, 12.5 etu after the start of transmission
  When SMR.GM = 0 and SMR.BLK = 1, 11.5 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 0, 11.0 etu after the start of transmission
  When SMR.GM = 1 and SMR.BLK = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When data for transmission are written to the TDR while the SCR.TE is 1

PER Flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (After writing 0 to it, read the PER bit to check that it has actually been cleared to 0.)
  Even when the RE bit in SCR is cleared to 0 (which indicates that serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS Flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR
  In RDR, the receive data prior to an overrun error occurrence is retained, but data received following the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be performed.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1 (After writing 0 to it, read the ORER bit to check that it has actually been cleared to 0.)
  Even when the RE bit in SCR is cleared to 0, the ORER flag is not affected and retains its previous value.

15.2.8 Smart Card Mode Register (SCMR)

	b7	b6	b5	b4	b3	b2	b1	b0
	BCP2	—	—	—	SDIR	SINV	—	SMIF
Value after reset:	1	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	SMIF	Smart Card Interface Mode Select	0: Serial communications interface mode 1: Smart card interface mode	R/W*1
b1	—	Reserved	This bit is read as 1. The write value should be 1.	R
b2	SINV	Transmitted/Received Data Invert	0: TDR contents are transmitted as they are. Receive data is stored as it is in RDR. 1: TDR contents are inverted before being transmitted. Receive data is stored in inverted form in RDR.	R/W*1
b3	SDIR	Transmitted/Received Data Transfer Direction	0: Transfer with LSB-first 1: Transfer with MSB-first	R/W*1
b6 to b4	—	Reserved	This bit is read as 1. The write value should be 1.	R
b7	BCP2	Base Clock Pulse 2	Selects the number of base clock cycles in combination with the SMR.BCP[1:0] bits. Setting values in the SCMR.BCP2 bit and SMR.BCP[1:0] bits BCP2 BCP1 BCP0 0 0 0: 93 clock cycles (S = 93)*2 0 0 1: 128 clock cycles (S = 128)*2 0 1 0: 186 clock cycles (S = 186)*2 0 1 1: 512 clock cycles (S = 512)*2 1 0 0: 32 clock cycles (S = 32)*2 (Initial Value) 1 0 1: 64 clock cycles (S = 64)*2 1 1 0: 372 clock cycles (S = 372)*2 1 1 1: 256 clock cycles (S = 256)*2	R/W*1

Note 1. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).
Note 2. S is the value of S in BRR (see section 15.2.9, Bit Rate Register (BRR)).

SMIF Bit (Smart Card Interface Mode Select)

When this bit is set to 1, smart card interface mode is selected.
When this bit is set to 0, asynchronous or clock synchronous mode is selected.

SINV Bit (Transmitted/Received Data Invert)

Inverts the transmit/receive data logic level. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR.

SDIR Bit (Transmitted/Received Data Transfer Direction)

Selects the serial/parallel conversion format.

BCP2 Bit (Base Clock Pulse 2)

Selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR.BCP[1:0] bits.

15.2.9 Bit Rate Register (BRR)

BRR is an 8-bit register that adjusts the bit rate.
As each SCI channel has independent baud-rate generator control, different bit rates can be set for each. Table 15.4 lists the relationships between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, and smart card interface mode.
The initial value of BRR is FFh.
BRR can be read from by the CPU at all times, but it can be written to only when the TE and RE bits in SCR are 0.

Table 15.4 Relationships between N Setting in BRR and Bit Rate B

Mode	ABCS Bit in SEMR	BRR Setting	Error
Asynchronous, multi-processor transfer	0	$N = \frac{P1\phi \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \{\frac{P1\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
	1	$N = \frac{P1\phi \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \{\frac{P1\phi \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1\} \times 100$
Clock synchronous		$N = \frac{P1\phi \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
Smart card interface		$N = \frac{P1\phi \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error\ (\%) = \{\frac{P1\phi \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1\} \times 100$

B: Bit rate (bps)
N: BRR setting for baud rate generator ($0 \le N \le 255$)
P1ϕ: Operating frequency (MHz)
n and S: Determined by the SMR setting listed in the following table.

Table 15.5 Clock Source Settings

SMR Setting		
CKS[1:0] Bits	**Clock Source**	**n**
0 0	P1ϕ clock	0
0 1	P1ϕ/4 clock	1
1 0	P1ϕ/16 clock	2
1 1	P1ϕ/64 clock	3

Table 15.6 Base Clock Settings in Smart Card Interface Mode

SCMR Setting	SMR Setting	Base Clock Cycles for One-bit Period	
BCP2 Bit	BCP[1:0] Bits		S
0	0 0	93 clock cycles	93
0	0 1	128 clock cycles	128
0	1 0	186 clock cycles	186
0	1 1	512 clock cycles	512
1	0 0	32 clock cycles	32
1	0 1	64 clock cycles	64
1	1 0	372 clock cycles	372
1	1 1	256 clock cycles	256

Table 15.7 lists sample N settings in BRR in normal asynchronous mode. Table 15.8 lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in clock synchronous mode are listed in Table 15.10. Examples of BRR (N) settings in smart card interface mode are listed in Table 15.12. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 15.6.4, Receive Data Sampling Timing and Reception Margin. Table 15.9 and Table 15.11 list the maximum bit rates with external clock input.

When the asynchronous mode base clock select bit (ABCS) in the serial extended mode register (SEMR) is set to 1 in asynchronous mode, the bit rate is two times that of listed in Table 15.7.

Table 15.7 Examples of BRR Settings for Various Bit Rates (Asynchronous Mode)

	Operating Frequency P1ϕ (MHz)								
	50			64			66.67

15.2.10 Serial Extended Mode Register (SEMR)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	NFEN	ABCS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	ABCS	Asynchronous Mode Base Clock Select	(Valid only in asynchronous mode) 0: Selects 16 base clock cycles for 1-bit period 1: Selects 8 base clock cycles for 1-bit period	R/W*1
b5	NFEN	Digital Noise Filter Function Enable	(In asynchronous mode) 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. The NFEN bit should be 0 in any mode other than above.	R/W*1
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

NFEN Bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function.

When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode.

In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function.

When the function is disabled, input signals are transferred as is, as internal signals.

15.2.11 Noise Filter Setting Register (SNFR)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	NFCS[2:0]	Noise Filter Clock Select	In asynchronous mode, the standard setting for the base clock is as follows. b2 b0 0 0 0: The clock signal divided by 1 is used with the noise filter. Other values: Do not make settings other than those listed above.	R/W*1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0. (both serial transmission and reception are disabled.)

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b.

15.2.12 Extended Function Control Register (SECR)

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CTSE	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R
b1	CTSE	CTS Enable	0: CTS pin function is disabled (RTS output function is enabled). 1: CTS pin function is enabled	R/W*1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing to this bit is only possible when the RE and TE bits in the SCR are 0 (both serial transmission and reception are disabled).

SECR is used to select the extension settings in asynchronous and clock-synchronous modes.

CTSE Bit (CTS Enable)

Set this bit to 1 if the CTS control signal is used for control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode.

15.3 Operation in Asynchronous Mode

Figure 15.2 shows the general format for asynchronous serial communications.
One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).
In asynchronous serial communications, the communications line is usually held in the mark state (high level).
The SCI monitors the communications line, and when it goes to the space state (low level), recognizes a start bit and starts serial communications.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

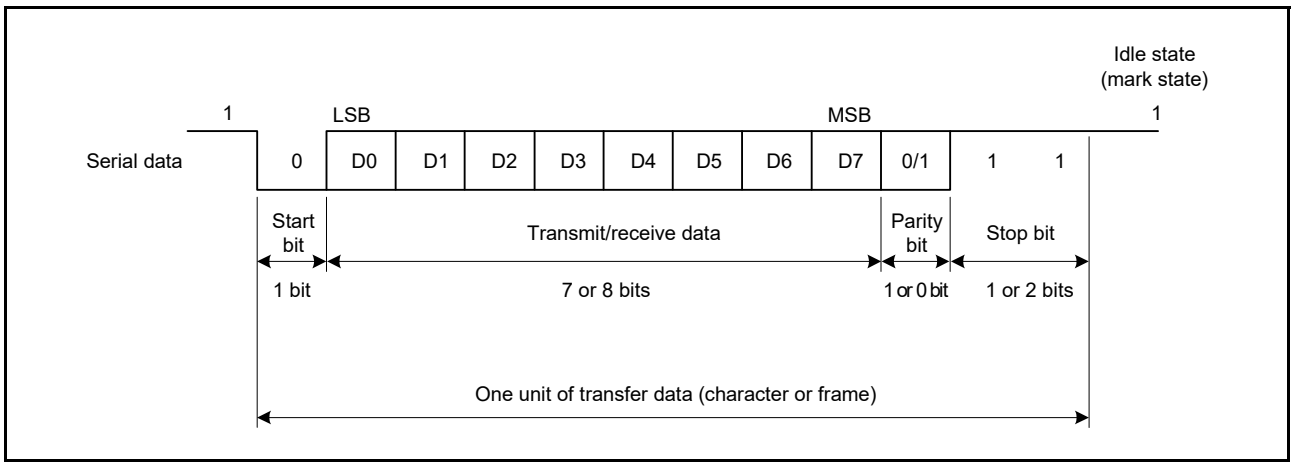

Figure 15.2 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, Two Stop Bits)

15.3.1 Serial Data Transfer Format

Table 15.14 lists the serial data transfer formats that can be used in asynchronous mode.
Any of 12 transfer formats can be selected according to the SMR setting. For details of multi-processor function, see section 15.4, Multi-Processor Communications Function.

Table 15.14 Serial Transfer Formats (Asynchronous Mode)

SMR Setting				Serial Transfer Format and Frame Length
CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12
0	0	0	0	S 8-bit data STOP
0	0	0	1	S 8-bit data STOP STOP
0	1	0	0	S 8-bit data P STOP
0	1	0	1	S 8-bit data P STOP STOP
1	0	0	0	S 7-bit data STOP
1	0	0	1	S 7-bit data STOP STOP
1	1	0	0	S 7-bit data P STOP
1	1	0	1	S 7-bit data P STOP STOP
0	—	1	0	S 8-bit data MPB STOP
0	—	1	1	S 8-bit data MPB STOP STOP
1	—	1	0	S 7-bit data MPB STOP
1	—	1	1	S 7-bit data MPB STOP STOP

S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

15.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.
In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 15.3. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\,F - \frac{D - 0.5}{N}\,(1+F) \right| \times 100\ [\%] \quad \cdots \text{ Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock (N = 16 when ABCS in SEMR = 0, N = 8 when ABCS in SEMR = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\%$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. This is an example when the ABCS bit in SEMR is 0. When the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock

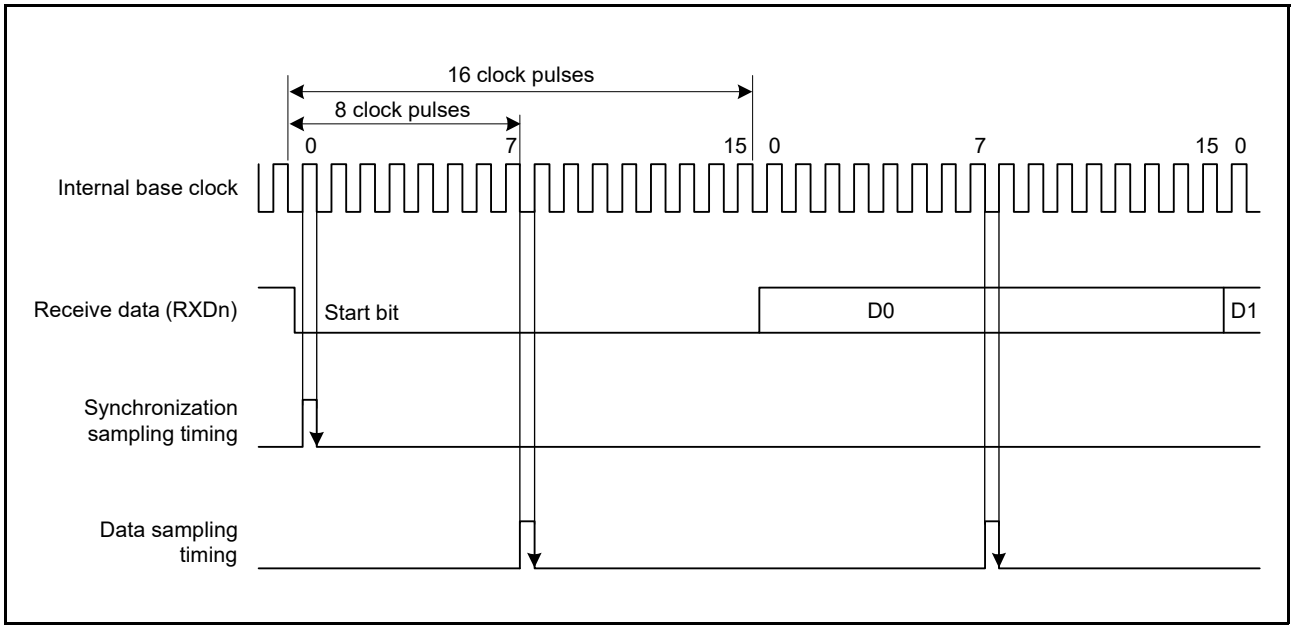

Figure 15.3 Receive Data Sampling Timing in Asynchronous Mode

15.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of the CM bit in SMR and the CKE[1:0] bits in SCR.
When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when ABCS in SEMR = 0) and 8 times the bit rate (when ABCS in SEMR = 1).
When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 15.4.

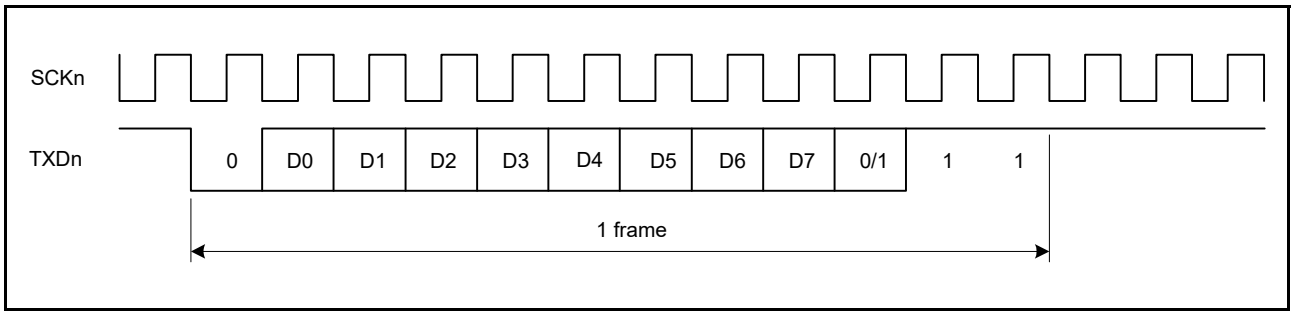

Figure 15.4 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode: SMR.CHR = 0, PE = 1, MP = 0, STOP = 1)

15.3.4 CTS and RTS Functions

The CTS function is the use of input on the CTSn# pin in transmission control. Setting the SECR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.
Applying the low level to the CTS# pin while transmission is in progress does not affect transmission of the current frame, which continues.
In the RTS function, by using the function of output on the RTSn# pin, a low level is output when reception becomes possible. Conditions for output of the low and high level are shown below.

[Conditions for low-level output]
Satisfaction of all conditions listed below

- The value of the RE bit in the SCR is 1
- Reception is not in progress
- There are no received data yet to be read
- The ORER, FER, and PER flags in the SSR are all 0

[Condition for high-level output]

- Any of the conditions for the low level not being satisfied

15.3.5 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, start by writing the initial value “00h” to SCR and then continue through the procedure for SCI given in the sample flowchart (Figure 15.5). Whenever the operating mode or transfer format is changed, SCR must be initialized before the change is made.
When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.
Note that clearing the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR nor RDR.
Moreover, note that switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt request.

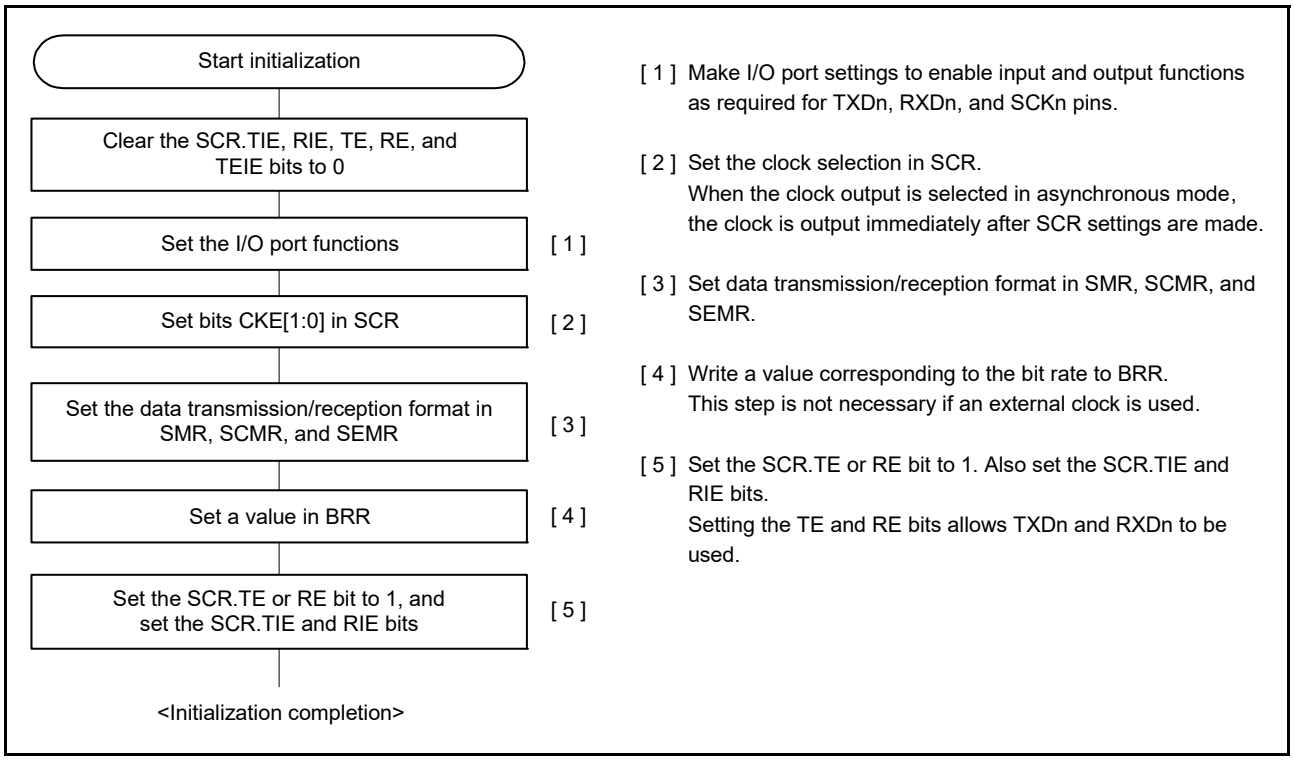

Figure 15.5 Sample SCI Initialization Flowchart (Asynchronous Mode)

15.3.6 Serial Data Transmission (Asynchronous Mode)

Figure 15.6 shows an example of the operation for serial transmission in asynchronous mode.
In serial transmission, the SCI operates as described below.

1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt processing routine. The TXI interrupt request at the beginning of transmission is generated when the TE bit in SCR is set to 1 after the TIE bit in SCR is set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CTSE bit in SECR is set to 0 (disabling the CTS function) and a low level on the CTS# pin causes data transfer from TDR to TSR. If the TIE bit in SCR is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next data for transmission to TDR in the TXI interrupt processing routine before transmission of the current data for transmission is completed. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (disabling TXI requests) and the SCR.TEIE bit to 1 (enabling TEI requests) after the last of the data to be transmitted are written to the TDR from the processing routine for TXI requests.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) TDR at the time of stop bit output.
5. When TDR is updated, setting of the CTSE bit in SECR to 0 (CTS function disabled) or a low level input on the CTSn# pin cause the next transfer of the next data for transmission from TDR to TSR and sending of the stop bit, after which serial transmission of the next frame starts.
6. If TDR is not updated, the TEND flag in SSR is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the TEIE flag in SCR is 1 at this time, the TEND flag in SSR is set to 1 and a TEI interrupt request is generated.

Figure 15.7 shows a sample flowchart for serial transmission in asynchronous mode.

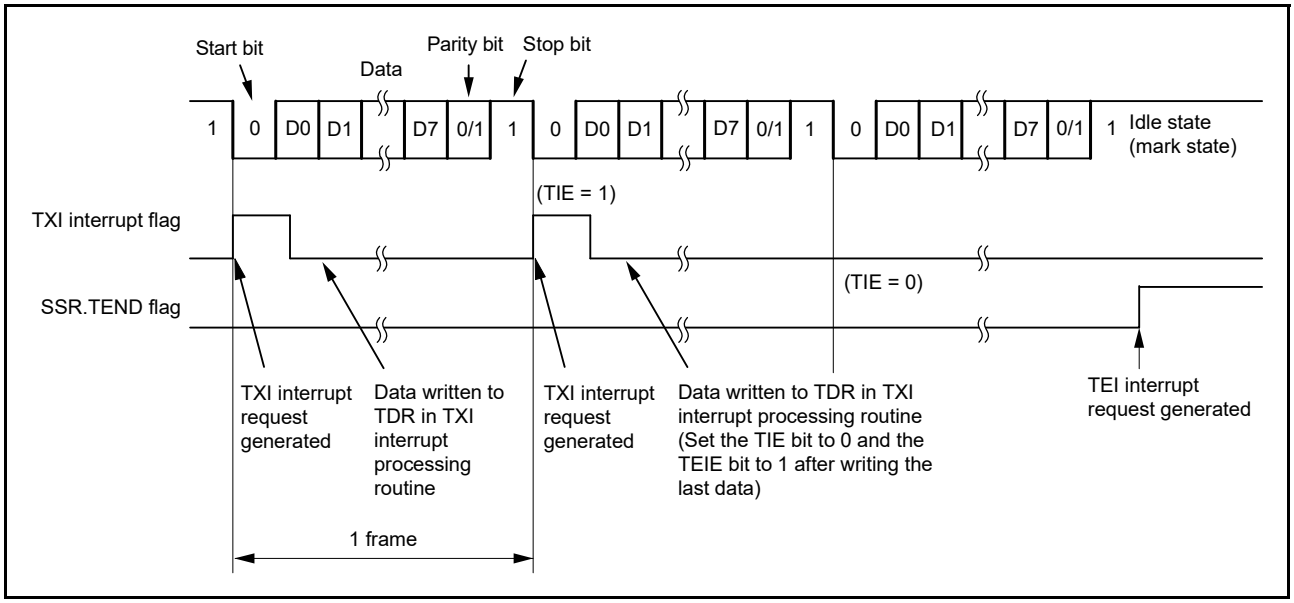

Figure 15.6 Example of Operation for Serial Transmission in Asynchronous Mode (from the Middle of Transmission until Transmission Completion) (Example with 8-Bit Data, Parity, One Stop Bit)

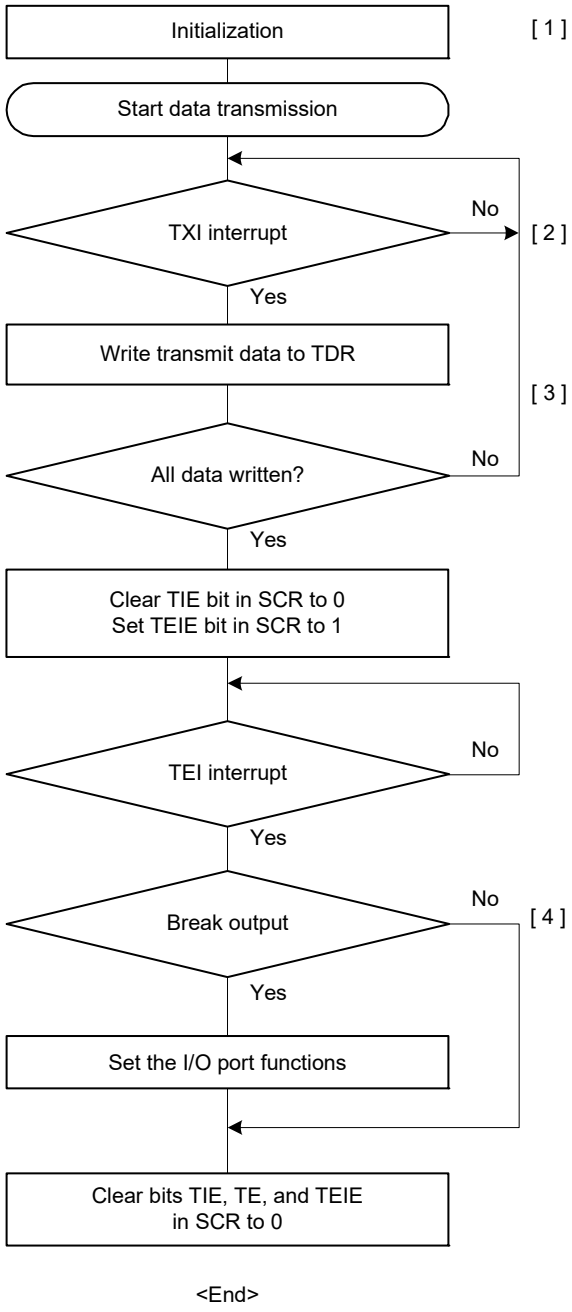

[1] Initialization:
The TXDn automatically becomes the output pin for data being transmitted.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to TDR by a TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.
Write transmit data to TDR once in the TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using a TXI interrupt request.
Transmit data can also be written to TDR by activating the direct access memory controller.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, set the general-purpose I/O port function corresponding to the TXDn pin (corresponding to output of the low level), and after switching the TXDn pin to the general-purpose I/O port function, set the TE bit in the SCR to 0.

Figure 15.7 Example of Serial Transmission Flowchart in Asynchronous Mode

15.3.7 Serial Data Reception (Asynchronous Mode)

Figure 15.8 and Figure 15.9 show examples of the operation for serial data reception in asynchronous mode.
In serial data reception, the SCI operates as described below.

1. When the value of the RE bit in SCR becomes 1, the output signal on the RTSn# pin goes to the low level.
2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the ORER flag in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR.
4. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to RDR. If the RIE bit in SCR is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR in this RXI interrupt processing routine before reception of the next receive data is completed. Reading out the received data that have been transferred to RDR causes the RTSn# pin to output the low level.

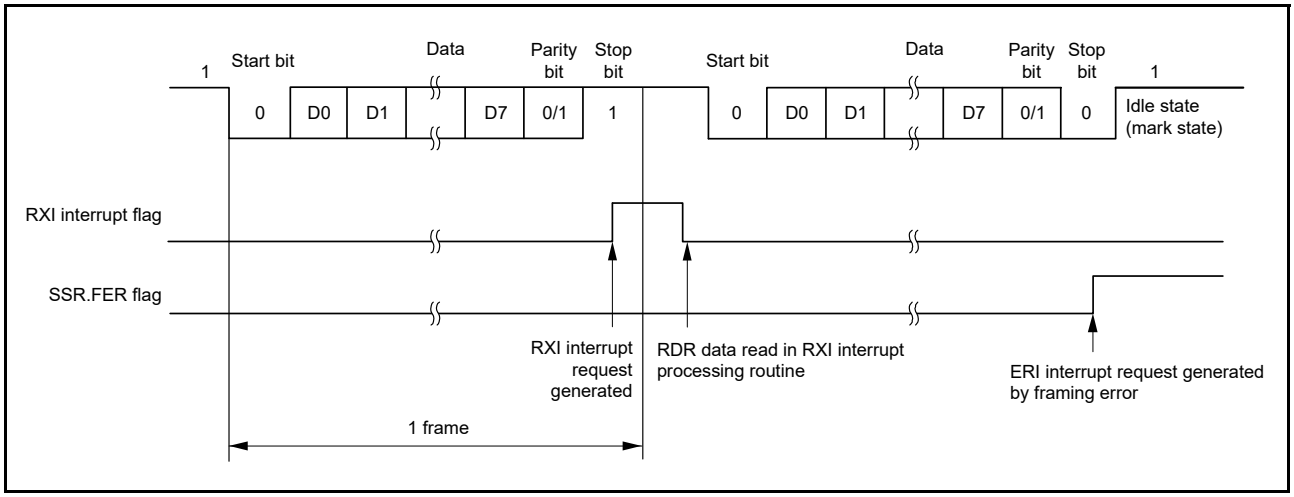

Figure 15.8 Example of SCI Operation for Serial Reception in Asynchronous Mode (1) (when RTS Function is not Used) (Example with 8-Bit Data, Parity, One Stop Bit)

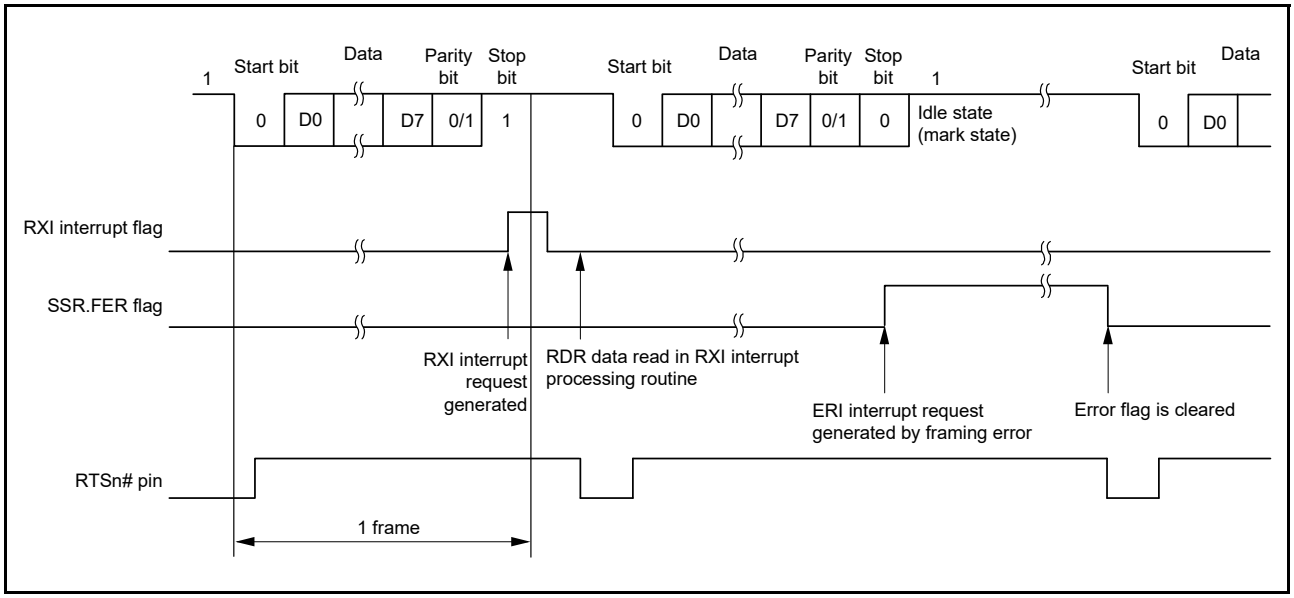

Figure 15.9 Example of SCI Operation for Serial Reception in Asynchronous Mode (2) (when RTS Function Is Used) (Example with 8-Bit Data, Parity, One Stop Bit)

Table 15.15 lists the states of the SSR status flags and receive data handling when a receive error is detected.
If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, clear the ORER, FER, and PER bits to 0 before resuming reception. Moreover, be sure to read the RDR during overrun error processing.
Figure 15.10 and Figure 15.11 show samples of flowcharts for serial data reception.

Table 15.15 SSR Status Flags and Receive Data Handling

SSR Status Flag				
ORER	**FER**	**PER**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

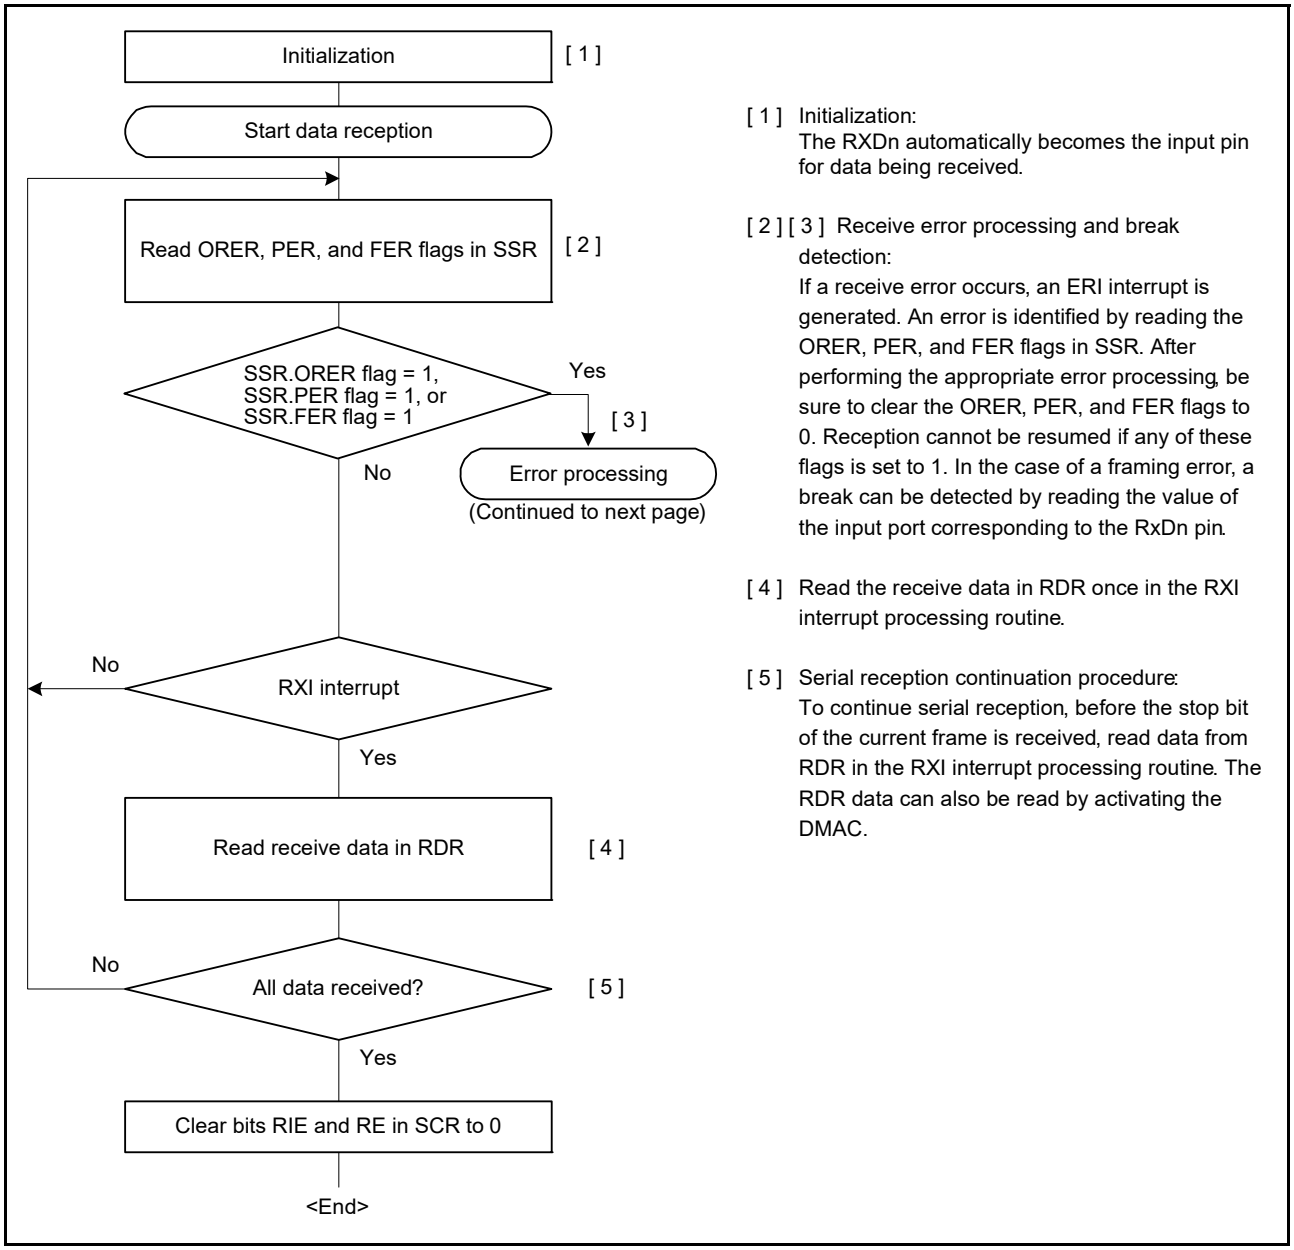

Figure 15.10 Example of Serial Reception Flowchart (1) (Asynchronous Mode)

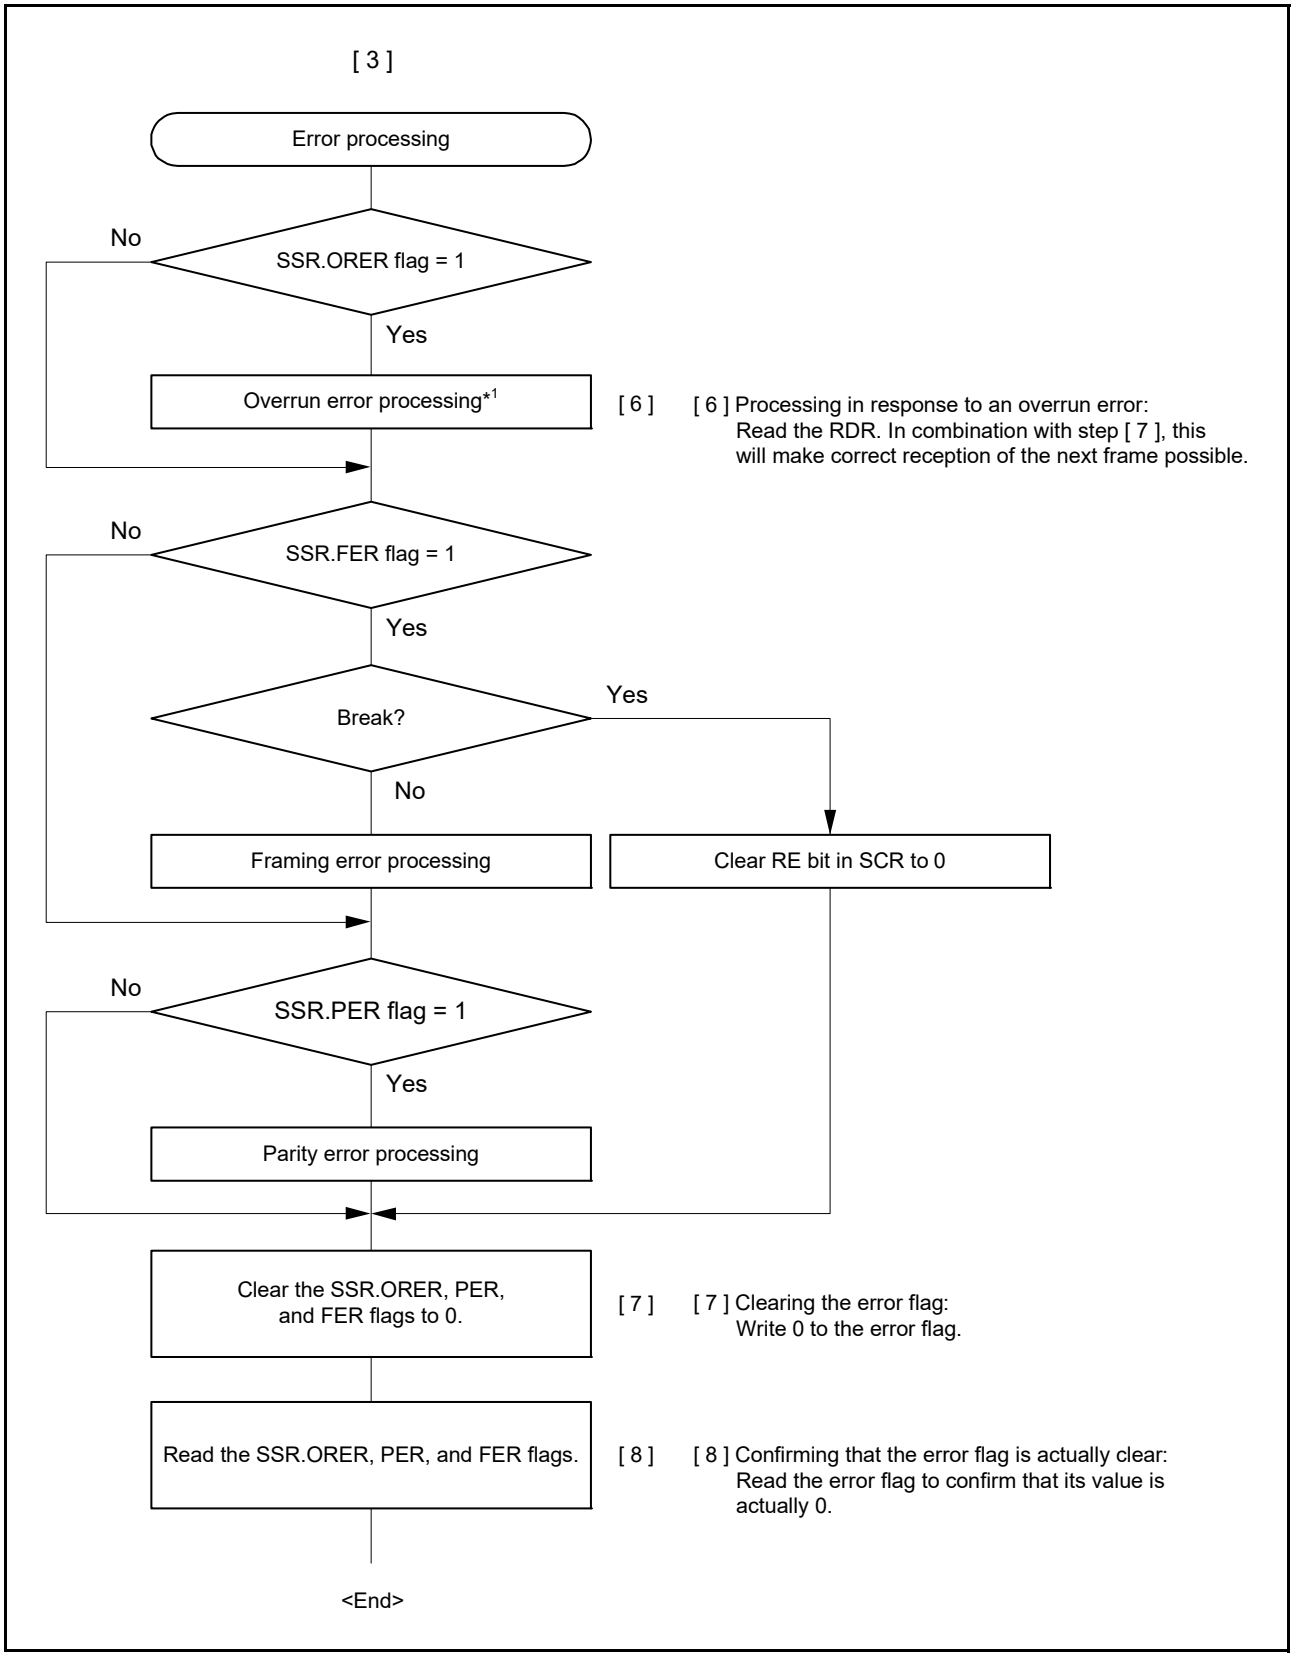

Figure 15.11 Example of Serial Reception Flowchart (2) (Asynchronous Mode)

15.4 Multi-Processor Communications Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multi-processor bit is set to 0, it indicates the data transmission cycle. Figure 15.12 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmission data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two match, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.

For supporting this function, the SCI provides the MPIE bit in SCR. When the MPIE bit in SCR is set to 1, transfer of receive data from the RSR to the RDR, detection of a reception error, and setting the respective status flags ORER and FER in SSR are disabled until reception of data in which the multi-processor bit is set to 1. Upon receiving a reception character in which the multi-processor bit is set to 1, the MPBT bit in SSR is set to 1 and the MPIE bit in SCR is automatically cleared, thus returning to a normal reception operation. During this time, an RXI interrupt is generated if the RIE bit in SCR is set.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the normal asynchronous mode.

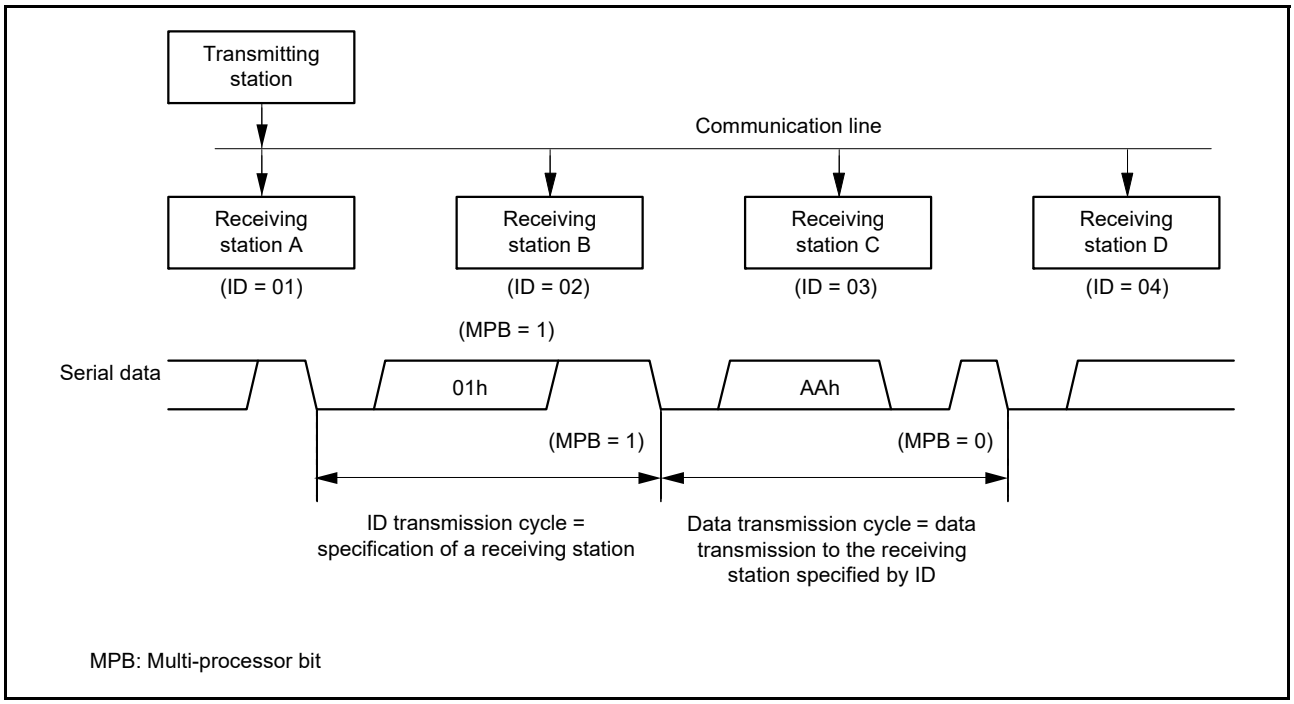

Figure 15.12 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)

15.4.1 Multi-Processor Serial Data Transmission

Figure 15.13 is a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in SSR set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

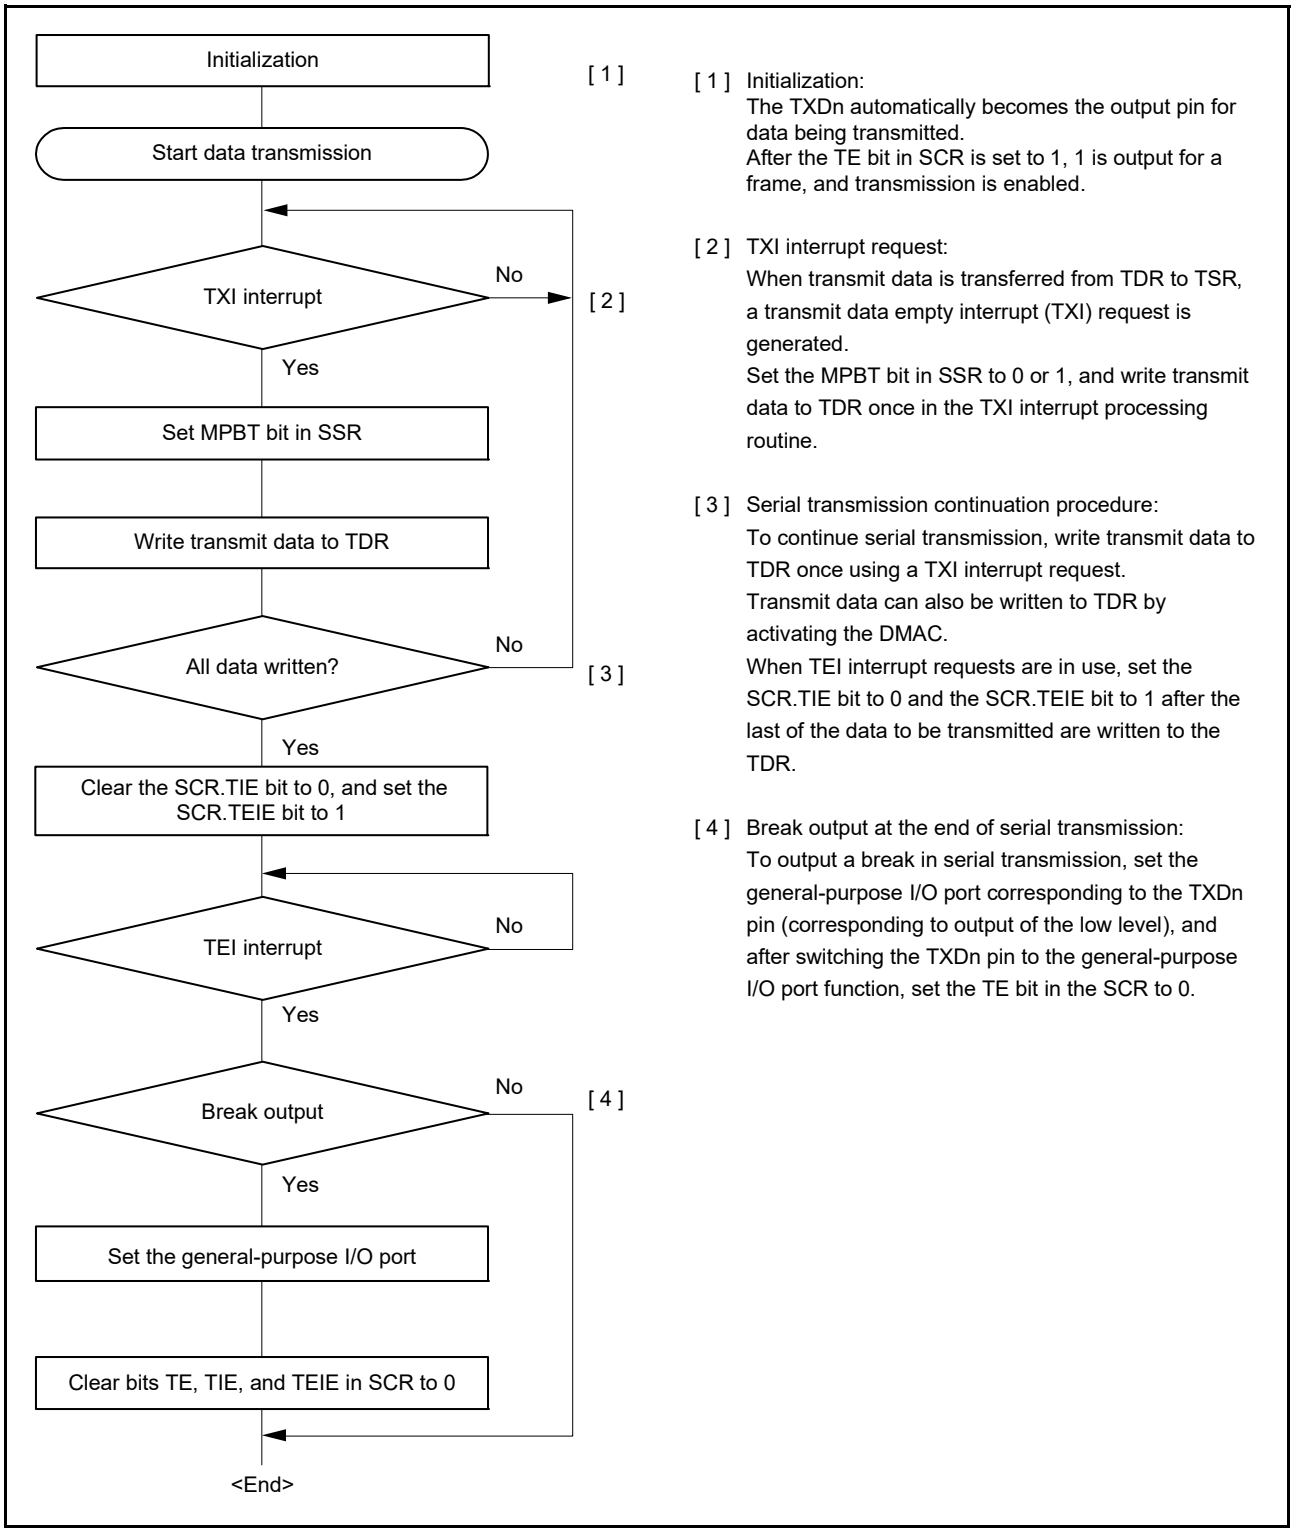

Figure 15.13 Example of Multi-Processor Serial Transmission Flowchart

15.4.2 Multi-Processor Serial Data Reception

Figure 15.15 and Figure 15.16 are sample flowcharts of multi-processor data reception. When the MPIE bit in SCR is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR. During this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode.
Figure 15.14 is the example of operation for reception.

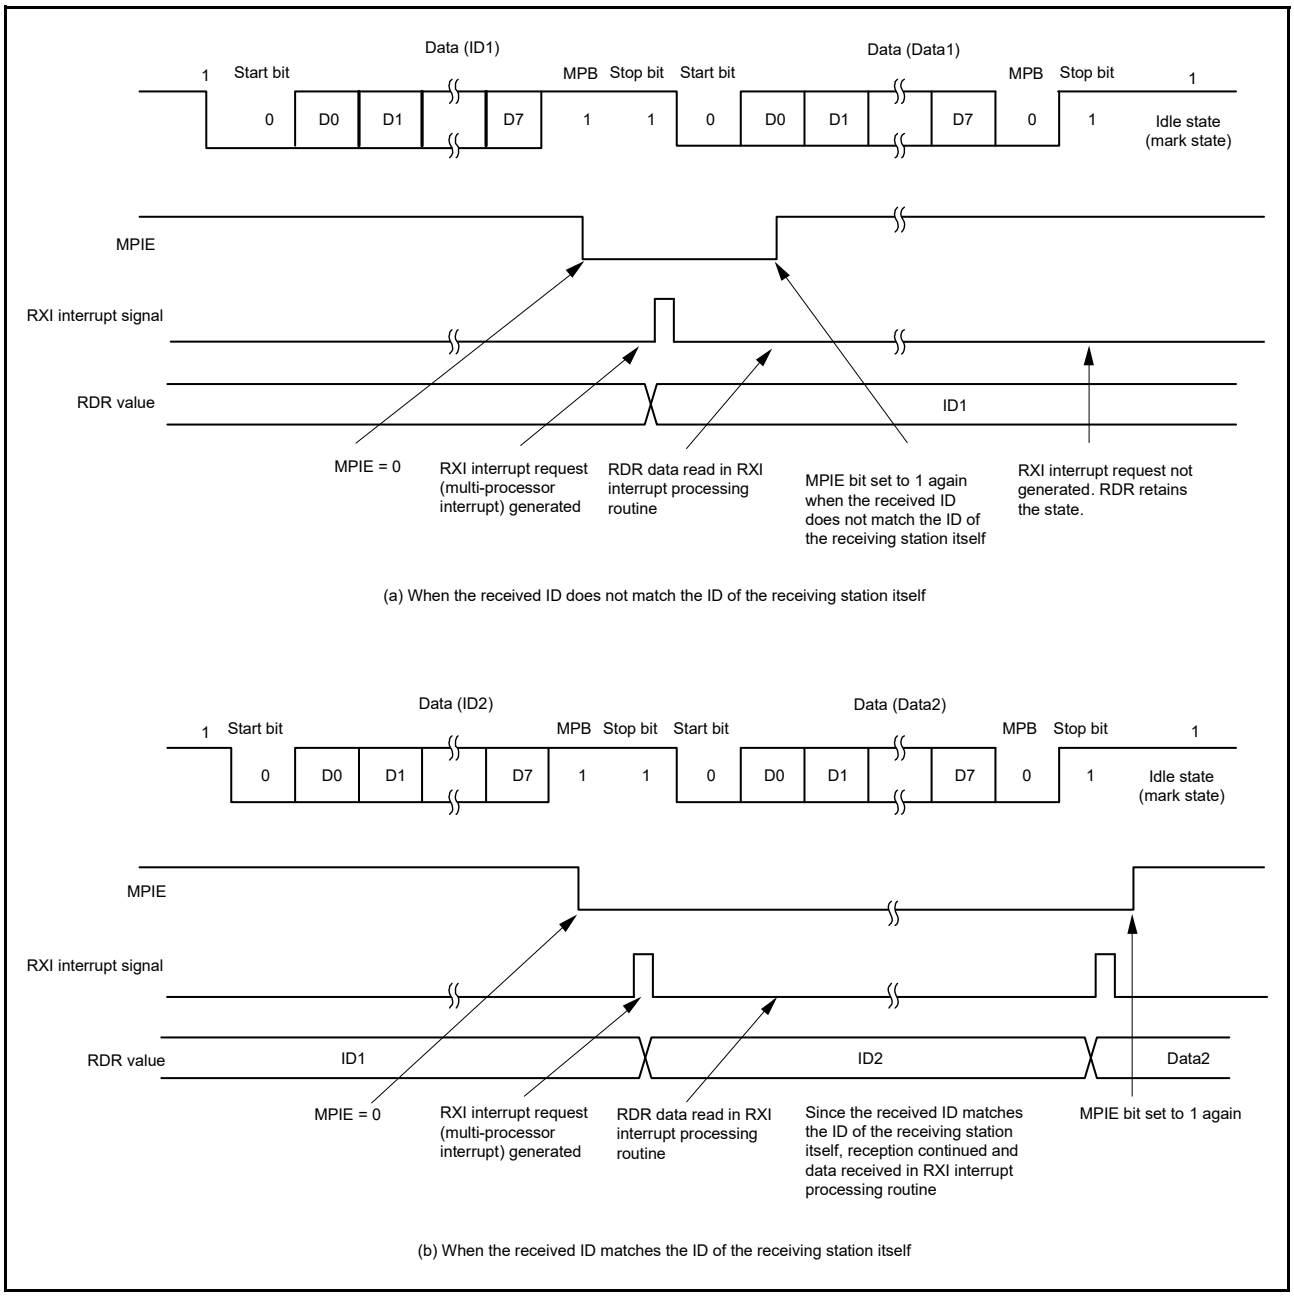

Figure 15.14 Example of Reception (8-Bit Data/Multi-Processor Bit/One Stop Bit)

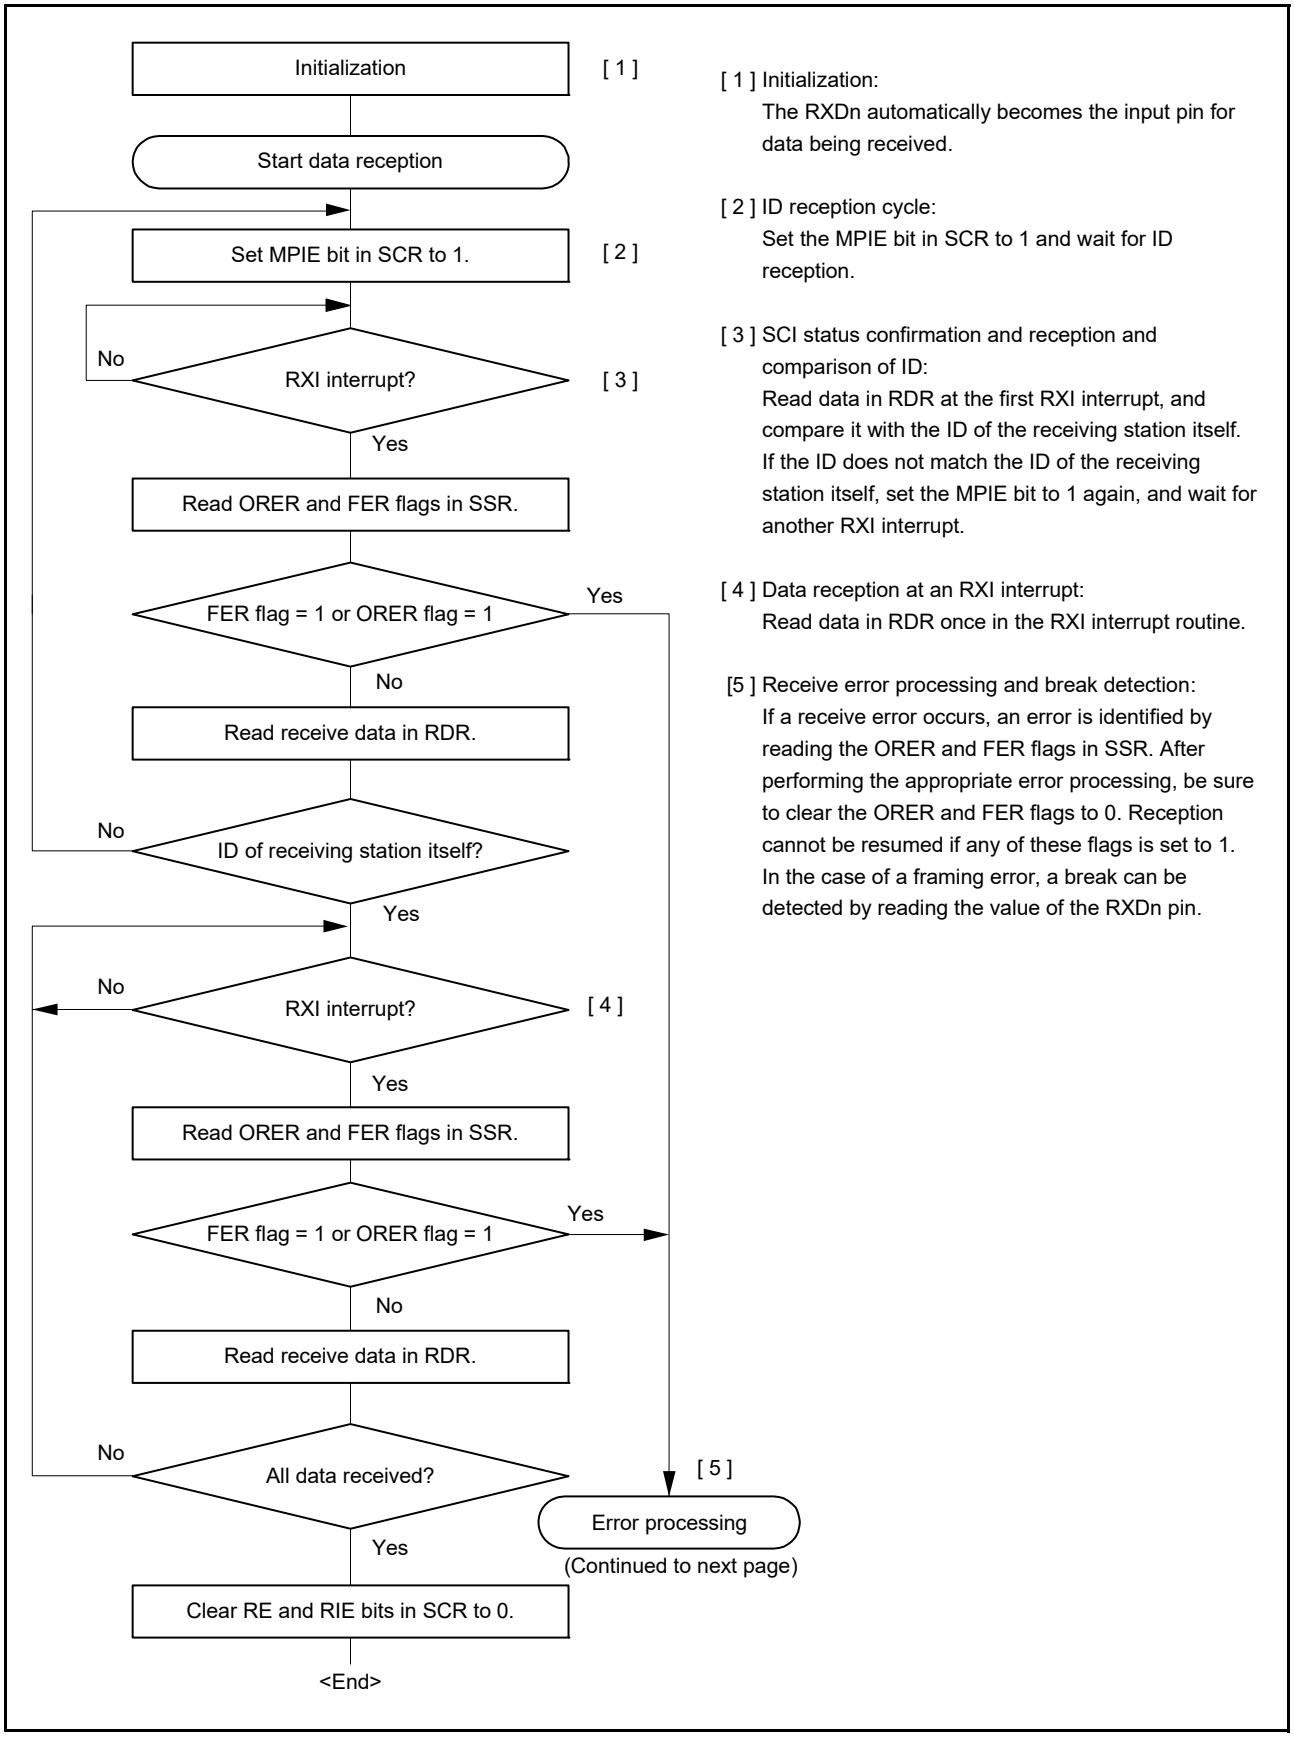

Figure 15.15 Example of Multi-Processor Serial Reception Flowchart (1)

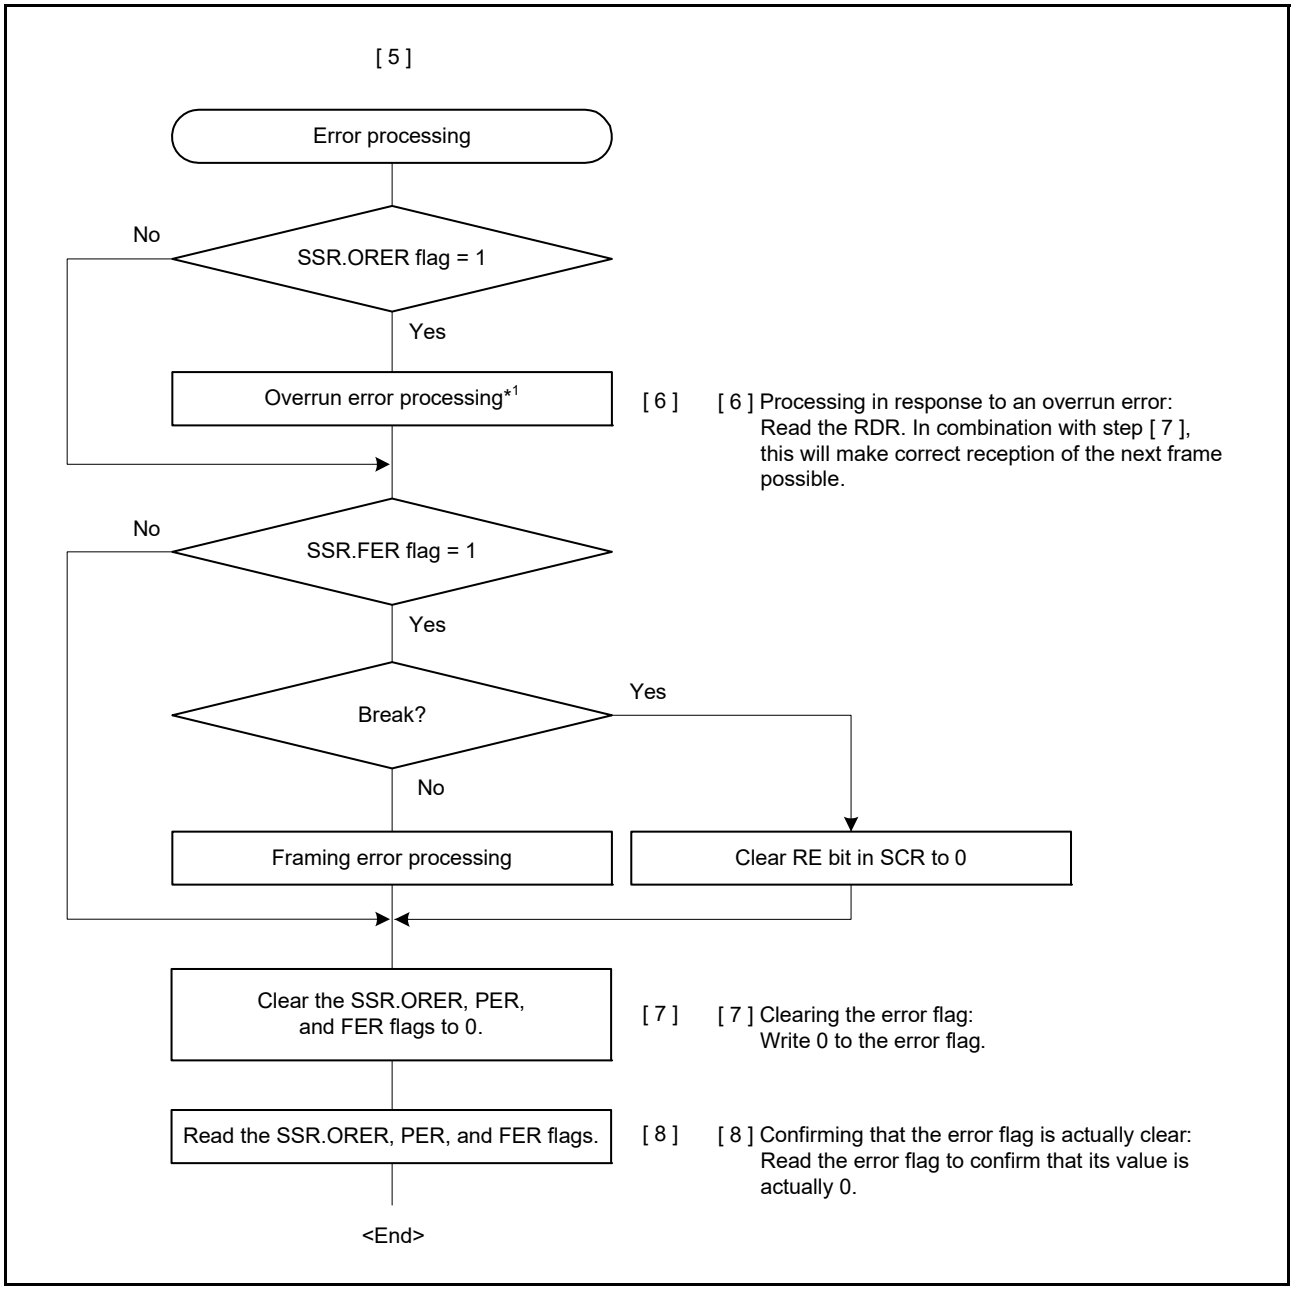

Figure 15.16 Example of Multi-Processor Serial Reception Flowchart (2)

15.5 Operation in Clock Synchronous Mode

Figure 15.17 shows the data format for clock synchronous serial data communications.
In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.
In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit output state.
Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

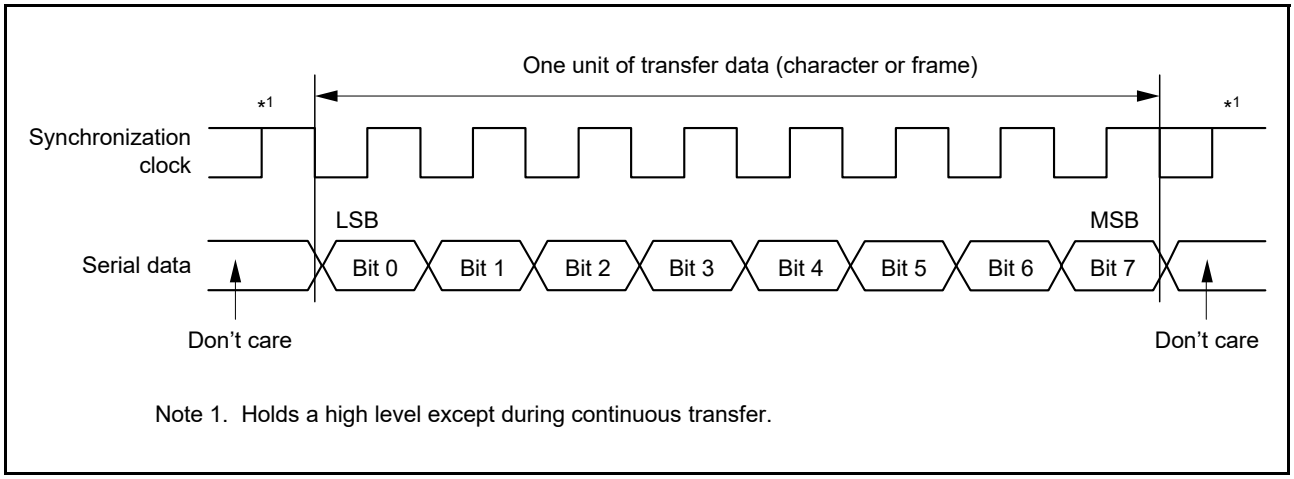

Figure 15.17 Data Format in Clock Synchronous Serial Communications (LSB-First)

15.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected, according to the setting of the CKE[1:0] bits in SCR.
When the SCI is operated on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is held high. However, when only data reception is performed, output of the synchronizing clock signal continues until the CTS function is enabled and the high level is input on the CTSn# pin, an overflow error occurs, or the RE bit in SCR is set to 0. When the CTS function is enabled, the synchronous clock signal output is stopped if the CTSn# pin input is high on completion of the frame reception.

15.5.2 CTS and RTS Functions

In the CTS function, CTSn# pin input is used to control reception/transmission start when the clock source is the internal clock. Setting the SECR.CTSE bit to 1 enables the CTS function.
When the CTS function is enabled, placing the low level on the CTSn# pin causes reception/transmission to start.
In the RTS function, RTSn# pin output is used to request reception/transmission start when the clock source is an external synchronizing clock. A low level is output when serial communications become possible. Conditions for output of the low and high level are shown below.

[Conditions for low-level output]
Satisfaction of all conditions listed below

- The value of the RE or TE bit in the SCR is 1
- Neither transmission nor reception is in progress
- There are no received data yet to be read (when the SCR.RE bit is 1)
- Transmit data has been written (when the SCR.TE bit is 1)
- ORER flag in SSR is 0

[Condition for high-level output]
Any of the conditions for the low level not being satisfied

15.5.3 Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, start by writing the initial value “00h” to the SCR and then continue through the procedure for SCI given in the sample flowchart (Figure 15.18). Whenever the operating mode or transfer format is changed, the SCR must be initialized before the change is made.
Note that clearing the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR nor RDR.
Moreover, note that switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt request.

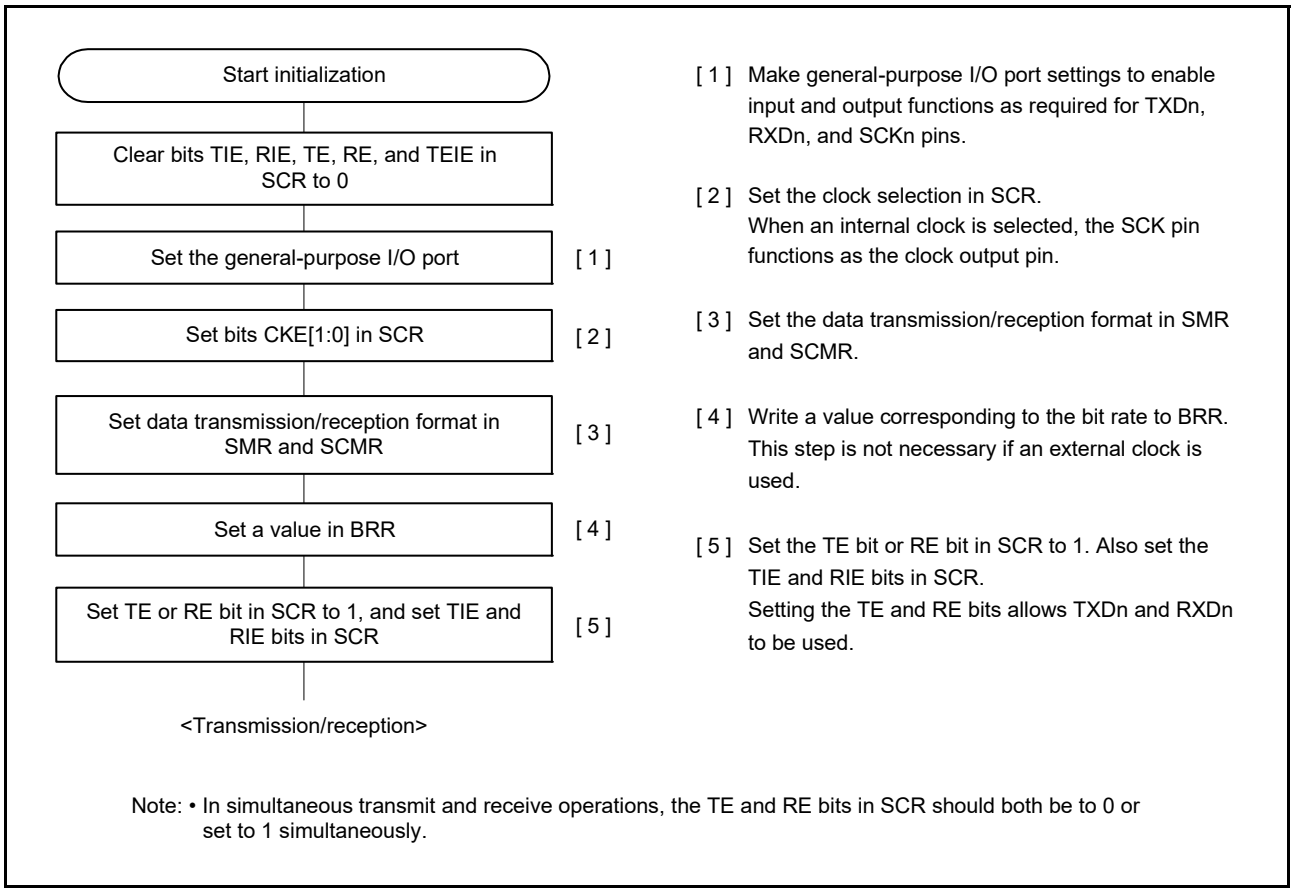

Figure 15.18 Example of Initialization Flowchart (Clock Synchronous Mode)

15.5.4 Serial Data Transmission (Clock Synchronous Mode)

Figure 15.19 shows an example of the operation for serial transmission in clock synchronous mode.
In serial data transmission, the SCI operates as described below.

1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt processing routine. The TXI interrupt request at the beginning of transmission is generated when the TE bit in SCR is set to 1 after the TIE bit in SCR is set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in this TXI interrupt processing routine before transmission of the current transmit data has finished. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (disabling TXI requests) and the SCR.TEIE bit to 1 (enabling TEI requests) after the last of the data to be transmitted are written to the TDR from the processing routine for TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when clock output mode has been specified and in synchronization with the input clock when use of an external clock has been specified. Output of the clock signal is suspended until the input CTS signal is at the low level while the CTSE bit in SECR is 1 (enabling the CTS function).
4. The SCI checks for updating of (writing to) the TDR at the time of the last bit output.
5. When TDR is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If TDR is not updated, set the SSR flag in TEND to 1 and the TXDn pin retains the output state of the last bit. If the TEIE bit in SCR is 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 15.20 shows a sample flowchart of serial data transmission.
Transmission will not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Be sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit in SCR to 0 does not clear the receive error flags.

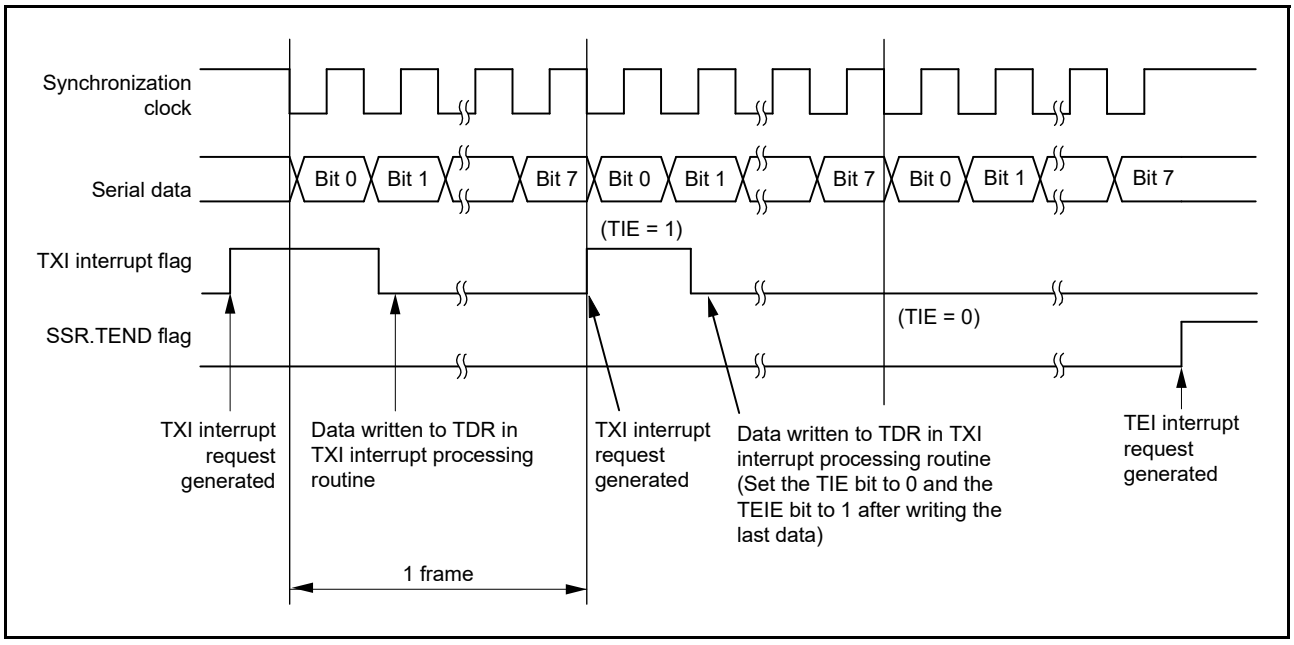

Figure 15.19 Example of Operation for Serial Transmission in Clock Synchronous Mode (from the Middle of Transmission until Transmission Completion)

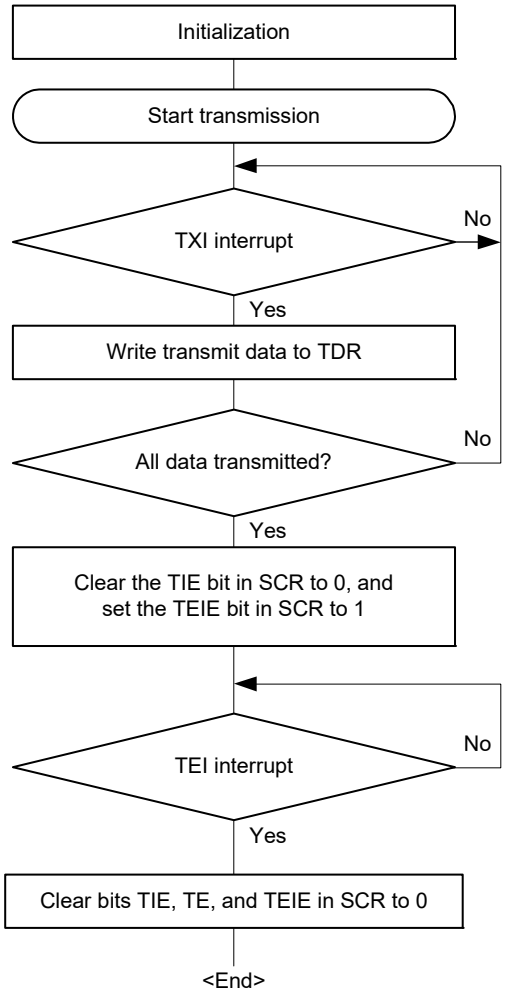

[1] Initialization:
The TXDn automatically becomes the output pin for data being transmitted.

[2] Writing transmit data write to TDR by a TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.
Transmit data is written to TDR once from the processing routine for TXI requests.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (TXI). Transmit data can also be written to TDR by activating the DMAC by the TXI interrupt request.
When TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted are written to the TDR.

Note: • When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR.TEND flag to 1. Clearing the SCR.TE bit to 0 immediately after this may lead to insufficient received-data hold time on the receiver side.

Figure 15.20 Example of Serial Transmission Flowchart (Clock Synchronous Mode)

15.5.5 Serial Data Reception (Clock Synchronous Mode)

Figure 15.21 and Figure 15.22 show examples of SCI operation for serial reception in clock synchronous mode. In serial data reception, the SCI operates as described below.

1. The value of the RE bit in SCR becoming 1 places the signal output on the RTS pin at the low level (when the RTS function is in use).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in RSR.
3. If an overrun error occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR.
4. When reception finishes successfully, receive data is transferred to RDR. If the RIE bit in SCR is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR in this RXI interrupt processing routine before reception of the next receive data is completed. Reading out the received data that have been transferred to RDR causes the RTSn# pin to output the low level (when the RTS function is in use).

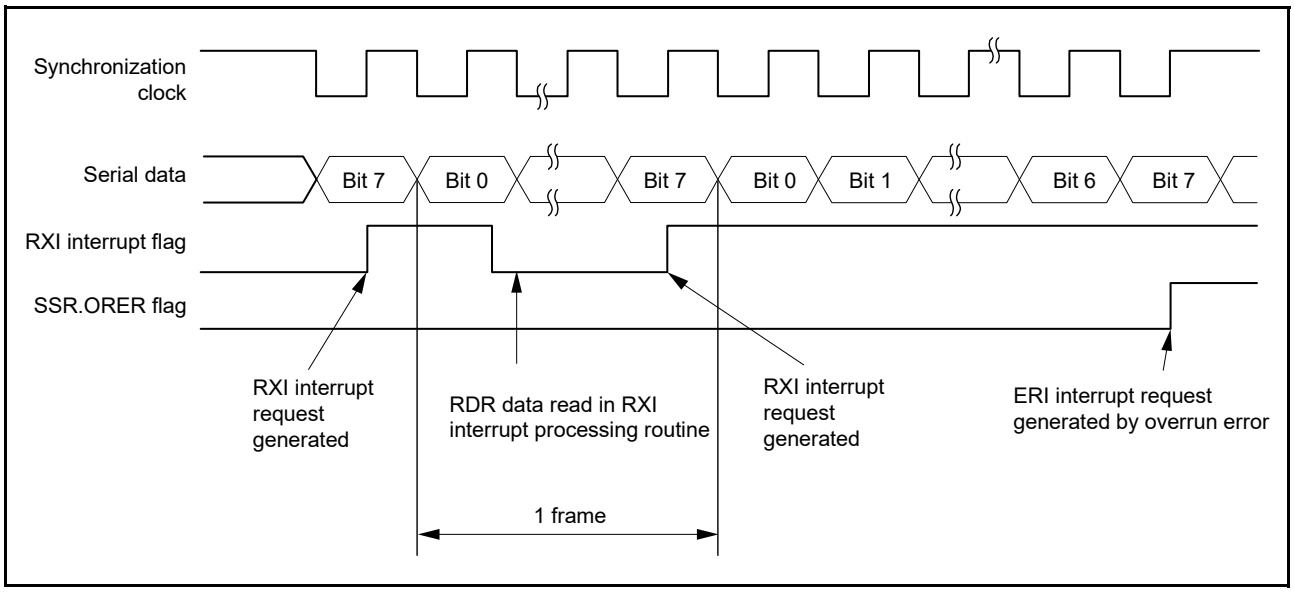

Figure 15.21 Example of Operation for Serial Reception in Clock Synchronous Mode (1) (when RTS Function is not Used)

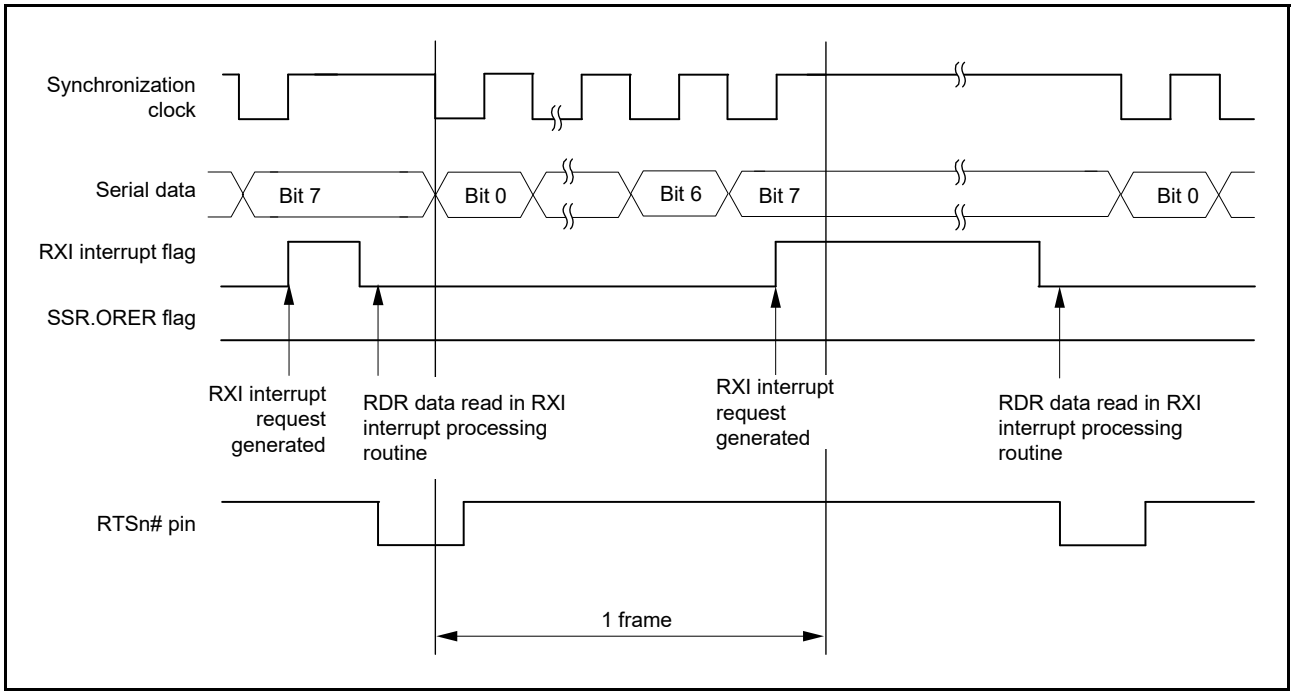

Figure 15.22 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (when RTS Function is Used)

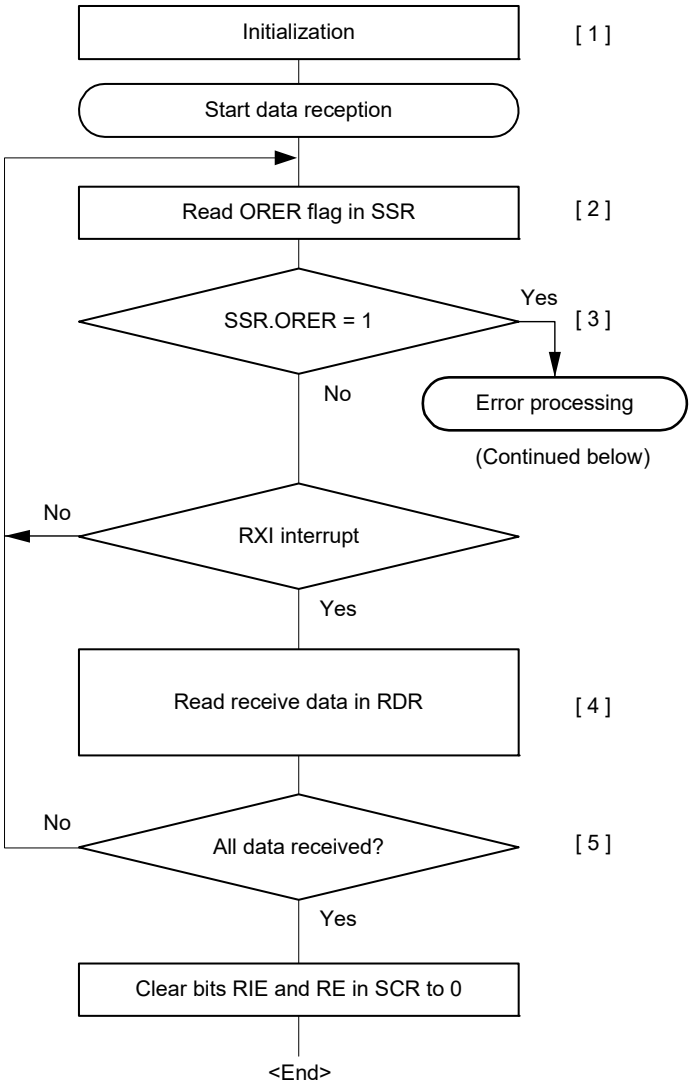
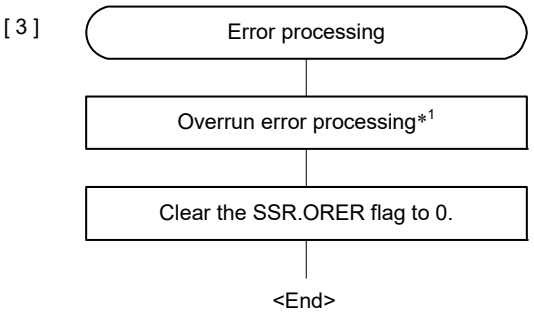
Data transfer cannot be resumed while a receive error flag is 1. Accordingly, clear the ORER, FER, and PER bits in SSR to 0 before resuming reception. Moreover, be sure to read the RDR during overrun error processing.

Figure 15.23 shows a sample flowchart for serial data reception.





[1] Initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, and then clear the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Read the receive data in RDR once in the receive data full interrupt (RXI) request processing routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in RDR. The RDR data can also be read by activating the DMAC by an RXI interrupt request.

[6] Clearing the error flag:
Clear the error flag to 0.
After writing 0, confirm that the flag is actually cleared.

Note1. Read RDR.

Figure 15.23 Example of Serial Reception Flowchart (Clock Synchronous Mode)

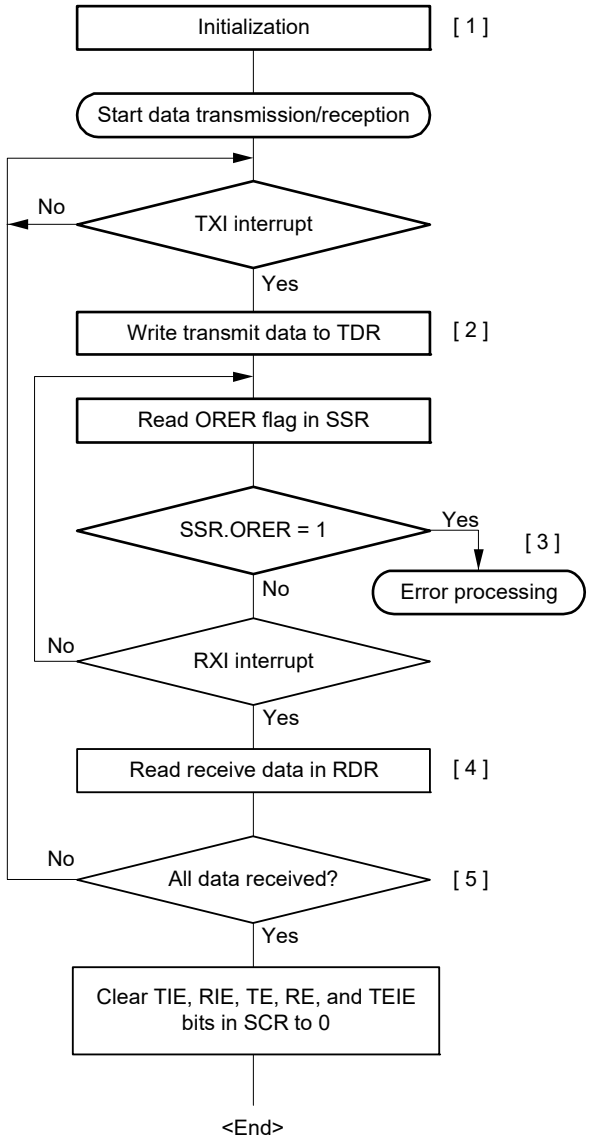
15.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 15.24 shows a sample flowchart for simultaneous serial transmit and receive operations in clock synchronous mode.

After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission by reading that the TEND flag in SSR is 1, and then initialize the SCR register. Then set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and then clear the RIE and RE bits to 0. Then check that the receive error flags (ORER, FER, and PER in SSR) are 0, and then set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.



[1] Initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to TDR once in the TXI interrupt request processing routine.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, and then clear the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in RDR once in the RXI interrupt request processing routine.

[5] Serial transmission/reception continuation procedure:
To continue serial transmission and reception, before the MSB (bit 7) of the current frame is received, finish reading the receive data in RDR by the RXI interrupt. Also, before the MSB (bit 7) of the current frame is transmitted, write data to TDR by the TXI interrupt.
Transmit data can also be written to TDR by activating the DMAC by a transmit data empty interrupt (TXI) request. Similarly, the RDR data can also be read by activating the DMAC by a receive data full interrupt (RXI) request.

Note: • When switching from transmit or receive operation to simultaneous transmit and receive operations, first clear the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, and then set TIE, RIE, TE, and RE bits to 1 simultaneously.

Figure 15.24 Example of Simultaneous Serial Transmission and Reception Flowchart (Clock Synchronous Mode)

15.6 Operation in Smart Card Interface Mode

The SCI supports the smart card (IC card) interface conforming to the ISO/IEC 7816-3 (Identification Card) standard. Smart card interface mode can be selected using the appropriate register.

15.6.1 Sample Connection

Figure 15.25 shows a sample connection between a smart card (IC card) and this LSI.
As in the figure, since this LSI communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to Vcc using a resistor.
Setting the TE and RE bits in SCR to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.
To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card. The output port of this LSI can be used to output a reset signal.

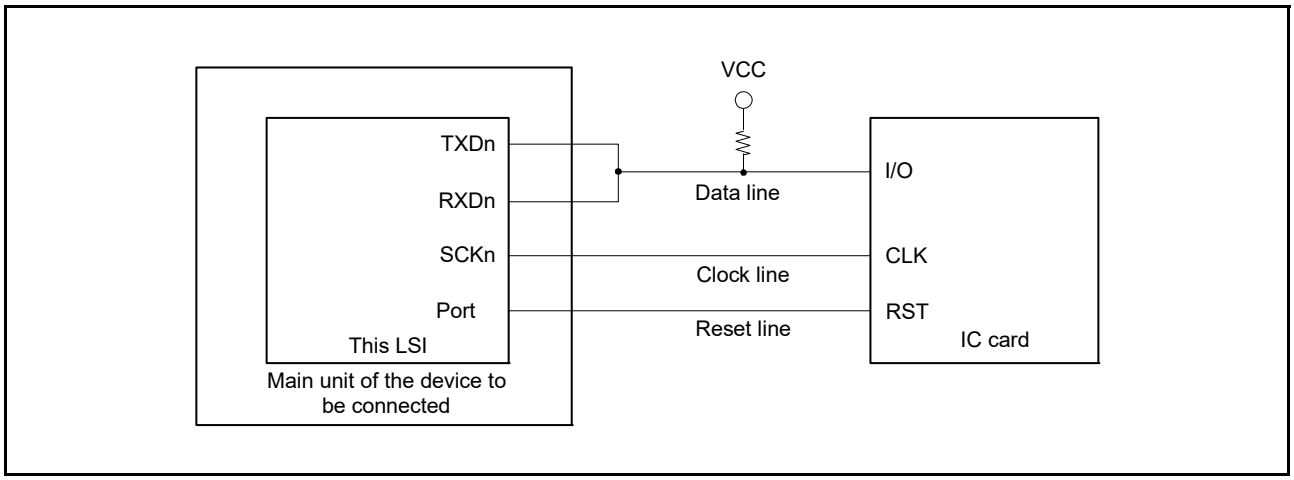


Figure 15.25 Sample Connection with a Smart Card (IC Card)

15.6.2 Data Format (Except in Block Transfer Mode)

Figure 15.26 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring one bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically re-transmitted after at least 2 etu.

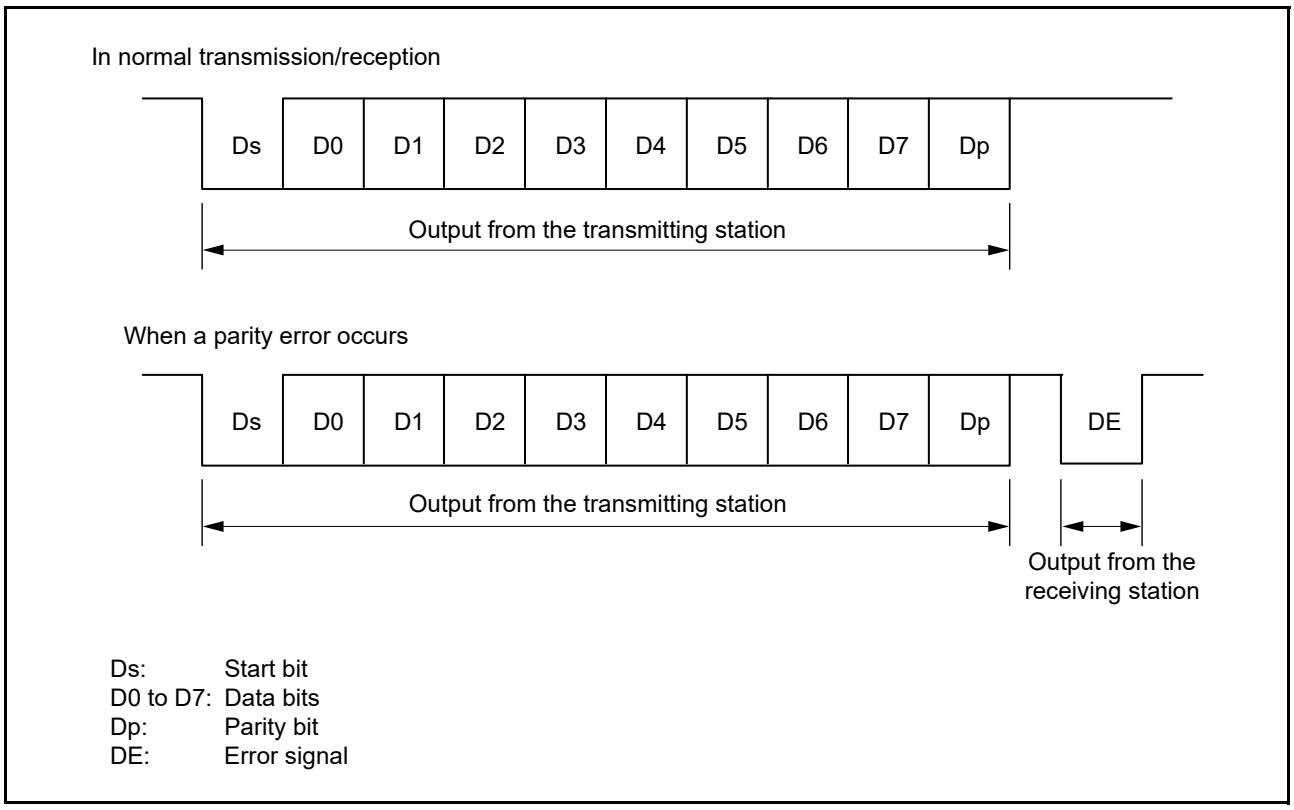

Figure 15.26 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB-first as the start character, as shown in Figure 15.27. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 0 to both the SDIR and SINV bits in SCMR. Write 0 to the PM bit in SMR in order to use even parity, which is prescribed by the smart card standard.

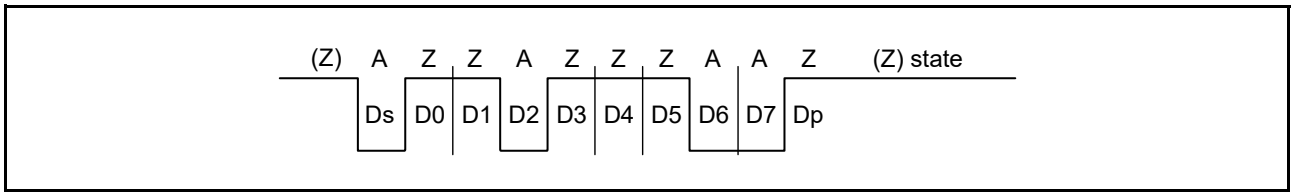

Figure 15.27 Direct Convention (SDIR in SCMR = 0, SINV in SCMR = 0, PM in SMR = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB-first as the start character, as shown in Figure 15.28. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 1 to both the SDIR and SINV bits in SCMR. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SCMR.SINV bit of this LSI only inverts data bits D7 to D0, write 1 to the PM bit in SMR to invert the parity bit for both transmission and reception.

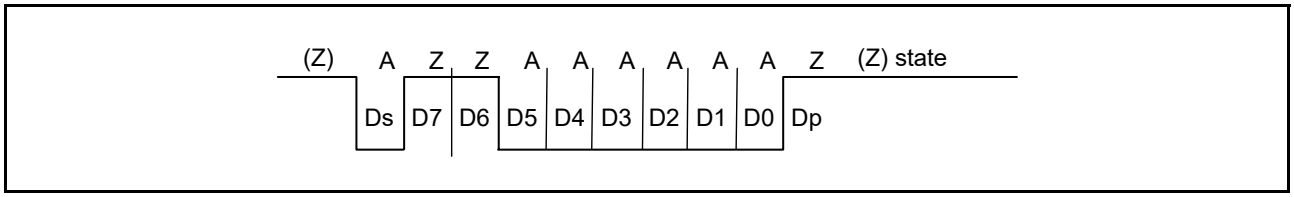

Figure 15.28 Inverse Convention (SDIR in SCMR = 1, SINV in SCMR = 1, PM in SMR = 1)

15.6.3 Block Transfer Mode

Block transfer mode is different from normal smart card interface mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the PER bit in SSR is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not re-transmitted during transmission, the TEND flag in SSR is set 11.5 etu after transmission start.
- In block transfer mode, the ERS flag in SSR indicates the error signal status as in normal smart card interface mode, but the flag is always read as 0 because no error signal is transferred.

15.6.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.
In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the BCP2 bit in SCMR and the BCP[1:0] bits in SMR (the frequency is always 16 times the bit rate in normal asynchronous mode).
For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 15.29. The reception margin here is determined by the following formula.

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\ F - \frac{\left| D - 0.5 \right|}{N}\ (1+F) \right| \times 100\ [\%]$$

M: Reception margin (%)
N: Ratio of bit rate to clock (N = 32, 64, 372, 256)
D: Duty cycle of clock (D = 0 to 1.0)
L: Frame length (L = 10)
F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\%$$

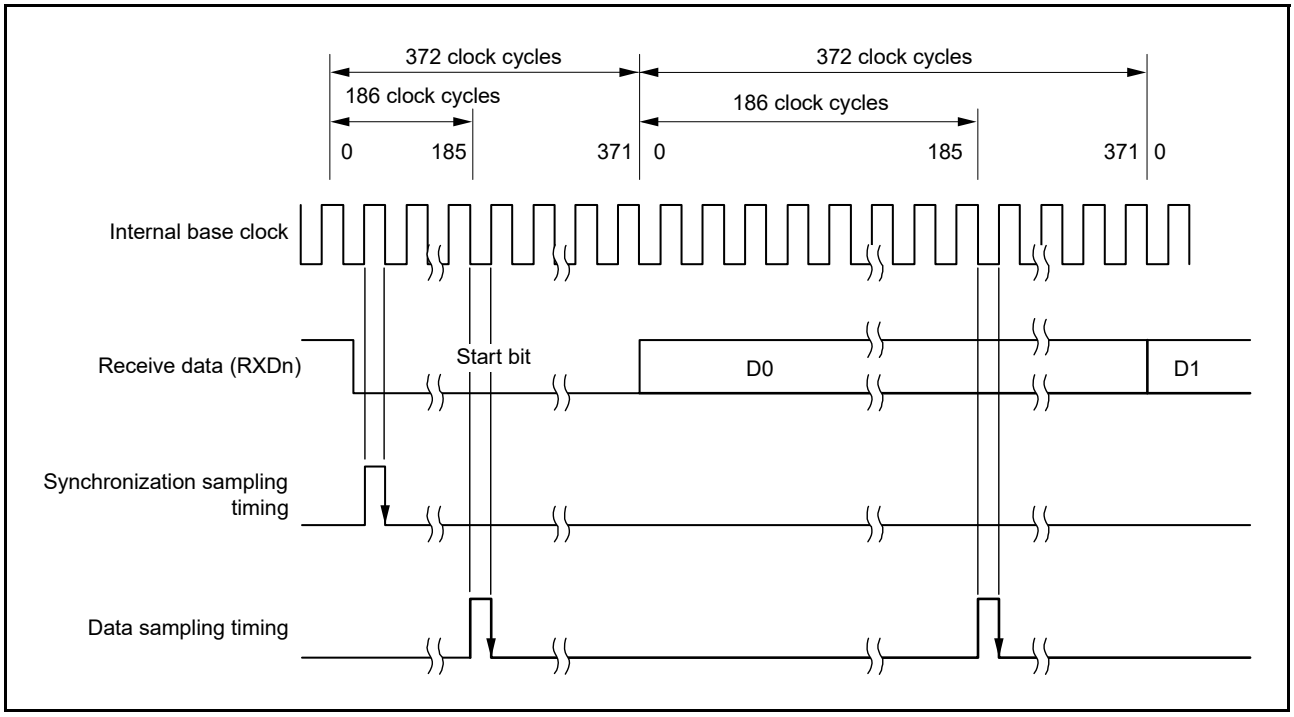

Figure 15.29 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)

15.6.5 Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, initialize the SCI using the following procedure. Initialization is also necessary before switching from transmission to reception and vice versa.

1. Write the initial value “00h” to the SCR.
2. Make general-purpose I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
3. Set the error flags ORER, ERS, and PER in SSR to 0.
4. Set bits GM, BLK, PM, BCP[1:0], and CKS[1:0] in SMR and the BCP2 bit in SCMR appropriately. Also set the PE bit in SMR to 1.
5. Set bits SDIR, SINV, and SMIF in SCMR appropriately. Then, the TXDn and RXDn pins are placed in the high impedance state.
6. Set the value corresponding to the bit rate in BRR.
7. Set the CKE[1:0] bits in SCR appropriately, and set bits TIE, RIE, TE, RE, and TEIE in SCR to 0 at the same time. When the CKE[1:0] bit in SCR is set to 1, the SCKn pin is allowed to output clock pulses.
8. Set the TIE, RIE, TE, and RE bits in SCR to 1. Setting the TE and RE bits to 1 simultaneously is prohibited except for self-diagnosis.

To change reception mode to transmission mode, first check that reception has completed, and then initialize the SCI. At the end of initialization, set SCR.TE = 1 and SCR.RE = 0. Reception completion can be verified by reading the RXI request, ORER, or PER flag in SSR.

To change transmission mode to reception mode, first check that transmission has completed, and then initialize the SCI. At the end of initialization, set SCR.TE = 0 and SCR.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR.

15.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be re-transmitted, is different from that in normal serial communications interface mode. Figure 15.30 shows the data retransfer operation during transmission.

1. When an error signal from the receiver end is sampled after one-frame data has been transmitted, the ERS flag in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag in SSR to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the TEND flag in SSR is not set. Data is retransferred from TDR to TSR allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag in SSR is not set to 1.
4. In this case, the SCI judges that transmission of one-frame data (including retransfer) has been completed, and the TEND flag is set. If the TIE bit in SCR is 1 at this time, a TXI interrupt request is generated. Writing transmit data to TDR starts transmission of the next data.

Figure 15.32 shows a sample flowchart of serial transmission. All the processing steps are automatically performed using a TXI interrupt request to activate the DMAC.
When the TEND flag in SSR is set to 1 in transmission, if the TIE bit in SCR is 1, a TXI interrupt request is generated. The DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of transmit data. The TEND flag in SSR is automatically cleared to 0 when the DMAC transfers the data.
If an error occurs, the SCI automatically re-transmits the same data. During this retransmission, the TEND flag in SSR is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag in SSR is not automatically cleared, set the RIE bit in SCR to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag in SSR to 0.
When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings.
For DMAC settings, see section 9, Direct Memory Access Controller.

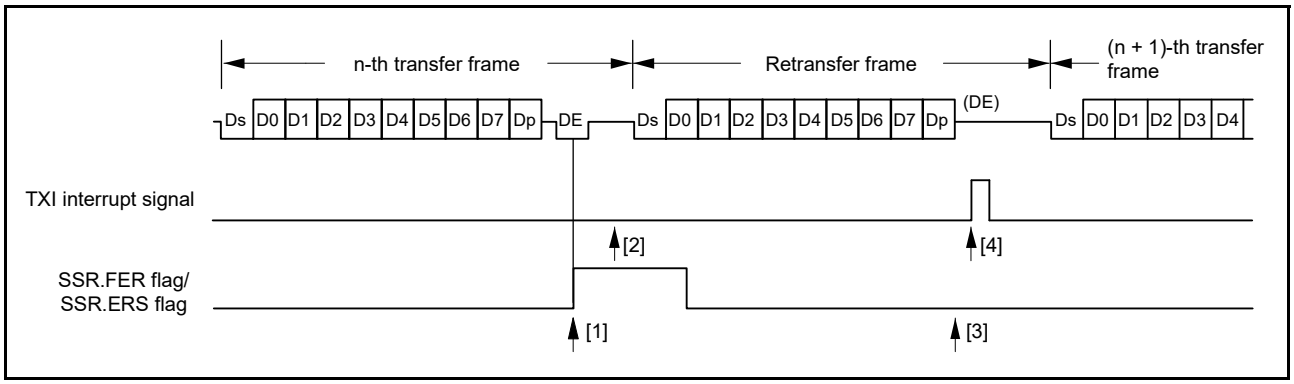

Figure 15.30 Data Retransfer Operation in Transmission Mode

Note that the SSR.TEND flag is set in different timings depending on the GM bit setting in SMR. Figure 15.31 shows the SSR.TEND flag generation timing.

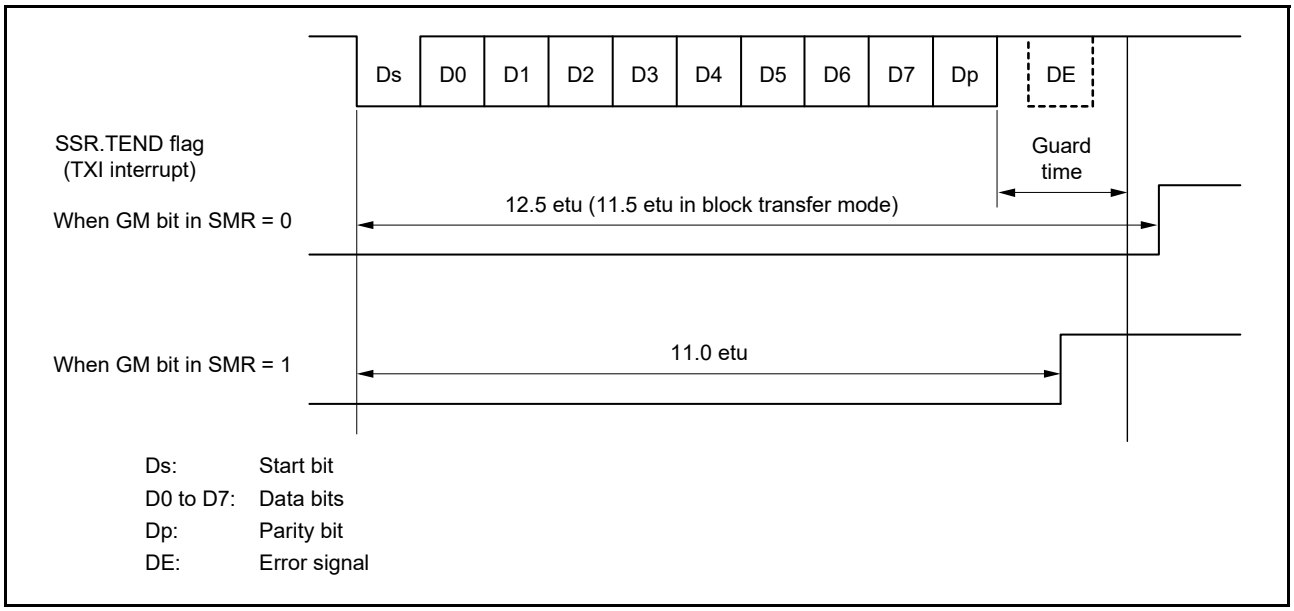

Figure 15.31 SSR.TEND Flag Generation Timing during Transmission

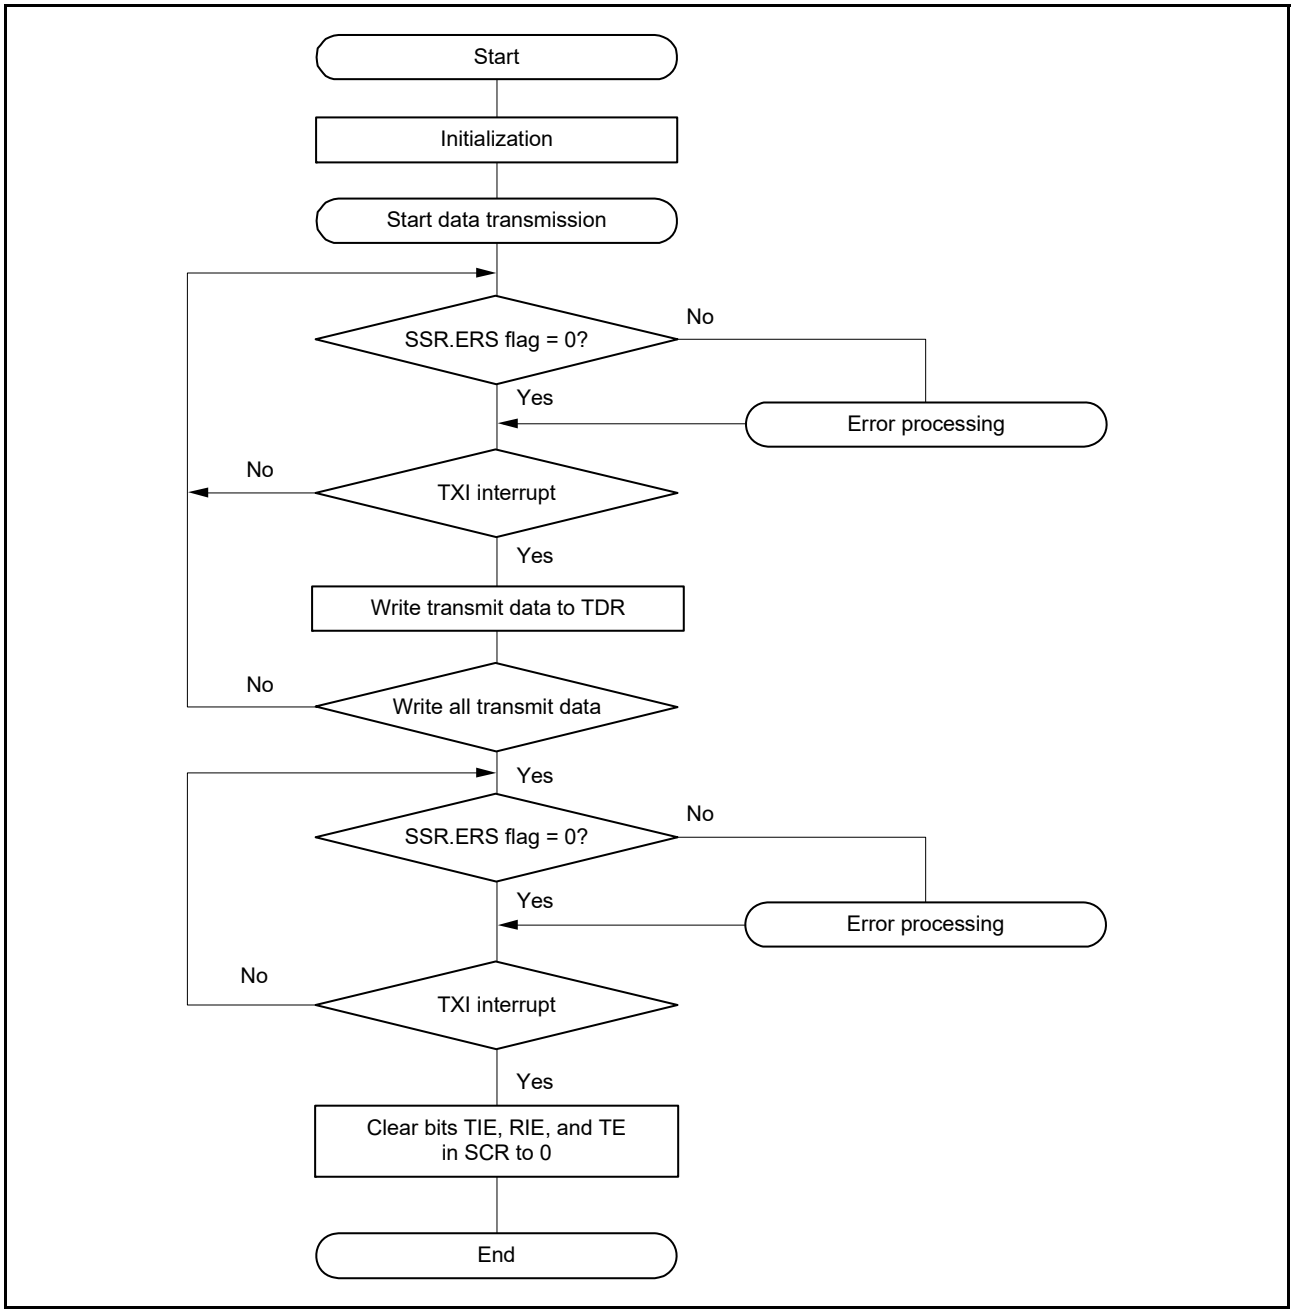

Figure 15.32 Sample Smart Card Interface Transmission Flowchart

15.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in serial communications interface mode. Figure 15.33 shows the data retransfer operation in reception mode.

1. If a parity error is detected in receive data, the PER flag in SSR is set to 1. When the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Clear the PER flag in SSR to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no RXI interrupt is generated.
3. When no parity error is detected, the PER flag in SSR is not set to 1.
4. In this case, data is determined to have been received successfully. When the RIE bit in SCR is 1, an RXI interrupt request is generated.

Figure 15.34 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DMAC.
In reception, setting the RIE bit in SCR to 1 allows an RXI interrupt request to be generated. The DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of receive data.
If an error occurs during reception and either the ORER or PER flag in SSR is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DMAC is transferred.
Even if a parity error occurs and the PER flag in SSR is set to 1 during reception, receive data is transferred to RDR, thus allowing the data to be read.
Note 1. For operations in block transfer mode, see section 15.3, Operation in Asynchronous Mode.

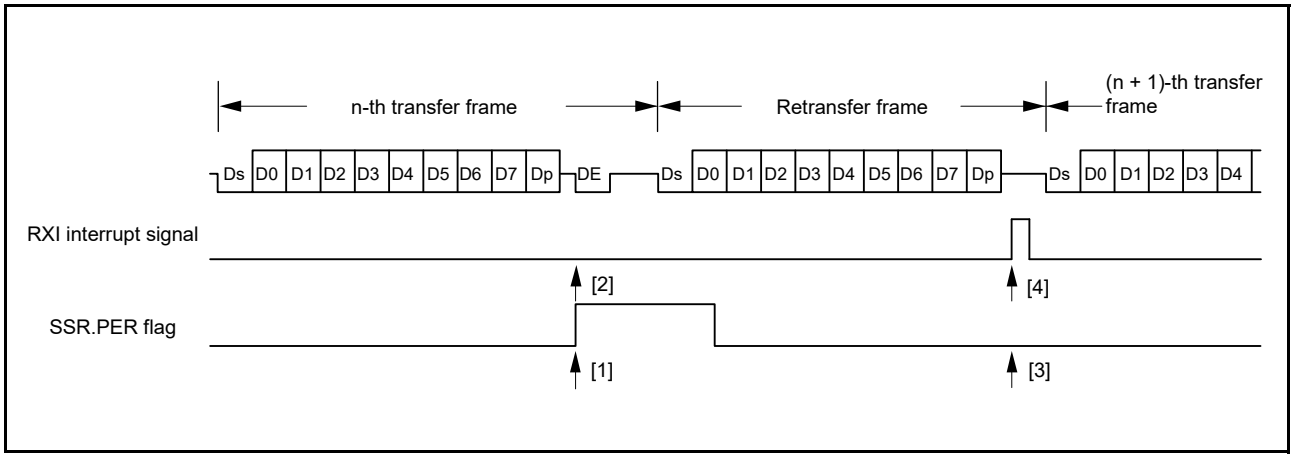

Figure 15.33 Data Retransfer Operation in Reception Mode

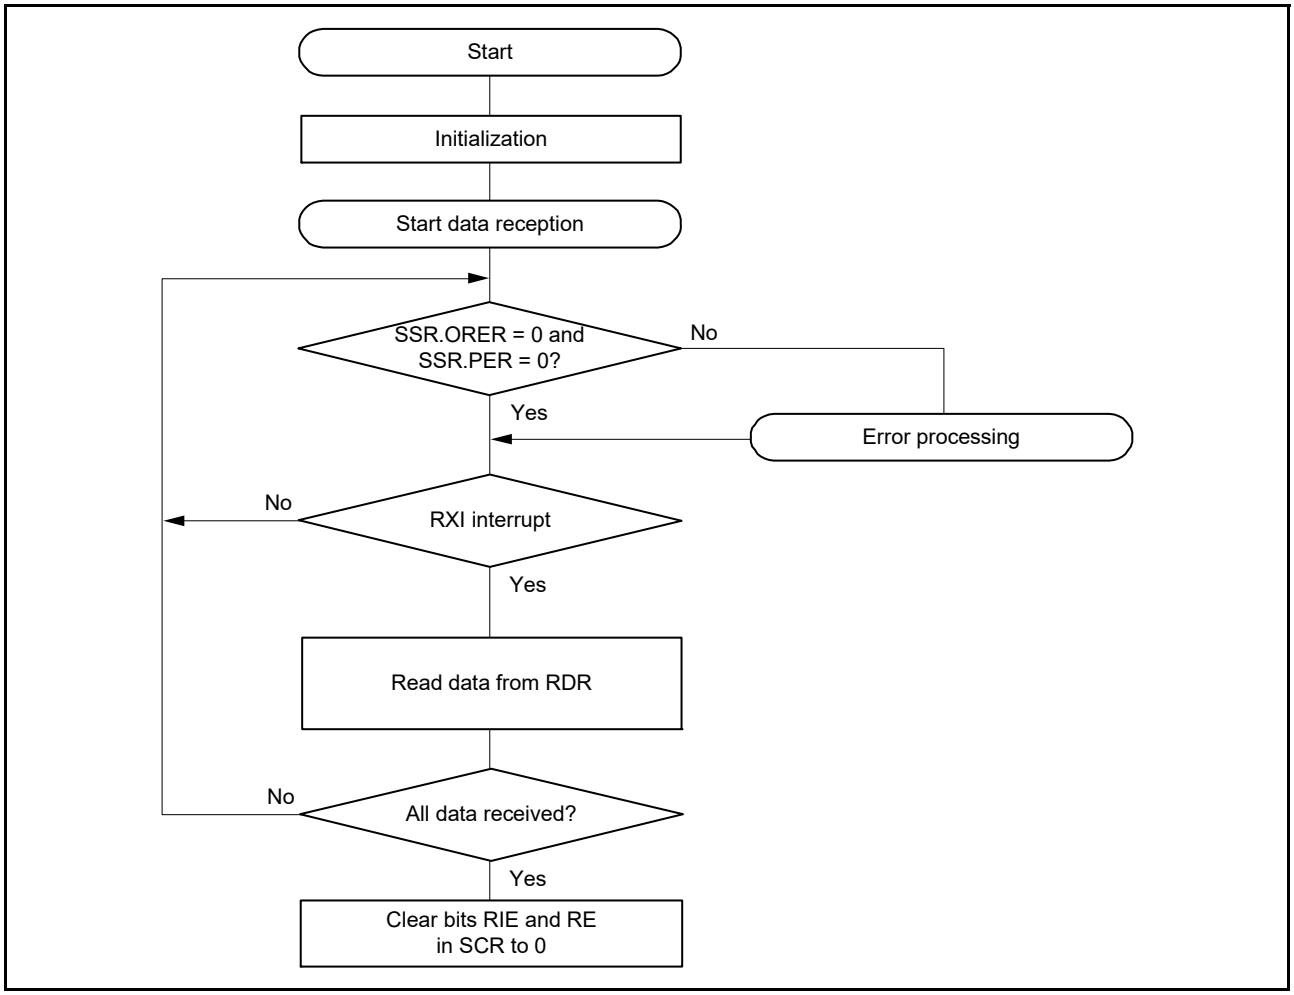

Figure 15.34 Sample Smart Card Interface Reception Flowchart

15.6.8 Clock Output Control

Clock output can be fixed using the CKE[1:0] bits in SCR when the GM bit in SMR is 1. Specifically, the minimum width of a clock pulse can be specified.

Figure 15.35 shows an example of clock output fixing timing when the CKE0 bit is controlled with SMR.GM = 1 and SCR.CKE1 = 0.

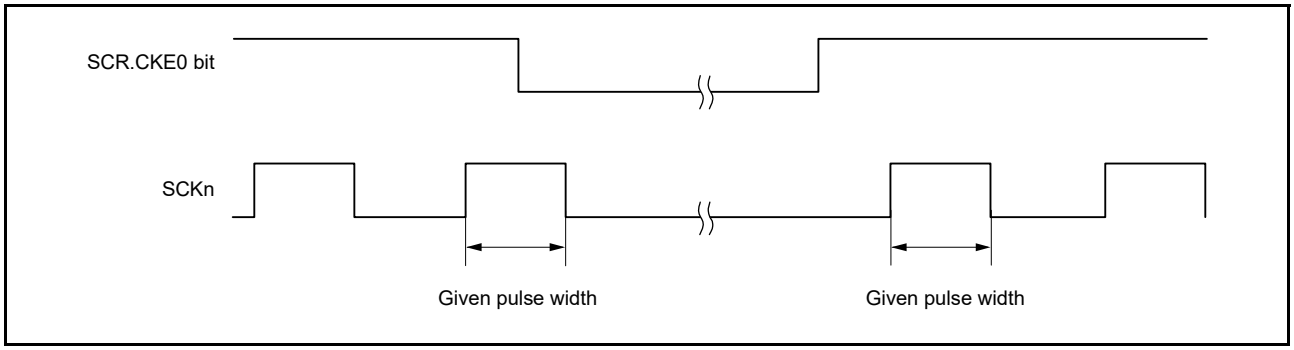

Figure 15.35 Clock Output Fixing Timing

At power-on and transitions to/from software standby mode, use the following procedure to secure the appropriate clock duty cycle.

(1) At Power-On

To secure the appropriate clock duty cycle simultaneously with power-on, use the following procedure.

1. Initially, port input is enabled in the high-impedance state. To fix the potential level, use a pull-up or pull-down resistor.
2. Fix the SCKn pin to the specified output by setting the SCR.CKE[1] bit and general-purpose I/O port.
3. Set SMR and SCMR to enable smart card interface mode.
4. Set the SCR.CKE[0] bit to 1 to start clock output.

(2) At Mode Switching

(a) At transition from smart card interface mode to software standby mode

1. Set low power consumption mode to make the SCKn pin fixed with a desired output value in software standby mode.
2. Write 0 to the TE and RE bits in SCR to stop transmission/reception.
   Simultaneously, set the SCR.CKE[1] bit to the value for the output fixed state in software standby mode.
3. Write 0 to the SCR.CKE[0] bit to stop the clock.
4. Wait for one cycle of the serial clock. In the mean time, the clock output is fixed to the specified level with the duty cycle retained.
5. After switching the SCKn pin to the general-purpose I/O port function, make a transition to software standby mode.

(b) Return from software standby mode to smart card interface mode

6. Cancel software standby mode.
7. Set the SCR.CKE[0] bit to 1 to start clock output. A clock signal with the appropriate duty cycle is then generated.

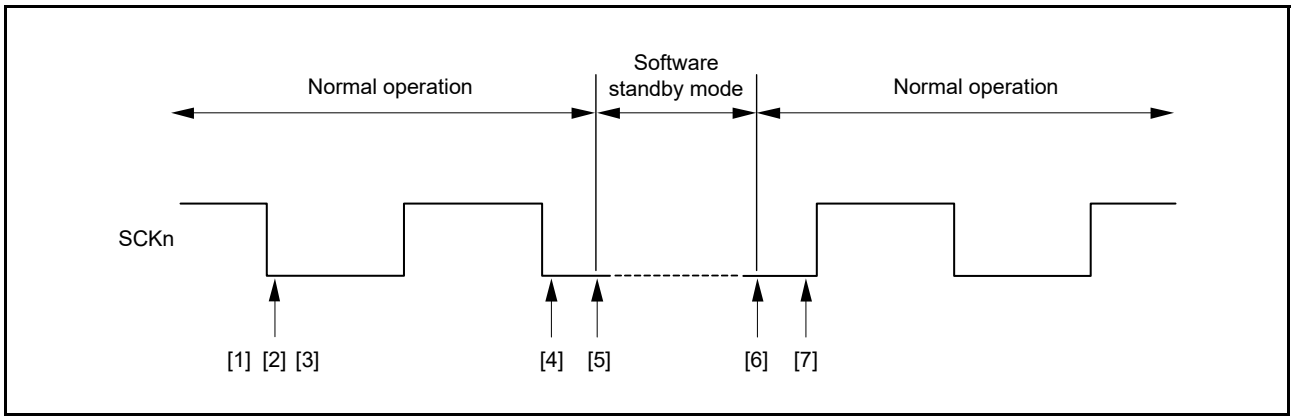

Figure 15.36 Clock Stop and Restart Procedure

15.7 Noise Cancellation Function

Figure 15.37 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of two stages of flip-flop circuits and a match-detection circuit. When the level on the pin matches in three consecutive samples taken at the set sampling interval, the matching level continues to be conveyed internally until the level on the pin again matches in three consecutive samples.

In asynchronous mode, the noise cancellation function can be applied on the RXDn input signal. The period of the base clock (1/16th of a bit-period when SEMR.ABCS = 0 and 1/8th of a bit-period when SEMR.ABCS = 1) is the sampling interval.

If the base clock is stopped with the noise filter enabled and then the clock input is started again, the noise filter operation resumes from where the clock was stopped. If SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed to the internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive samples.

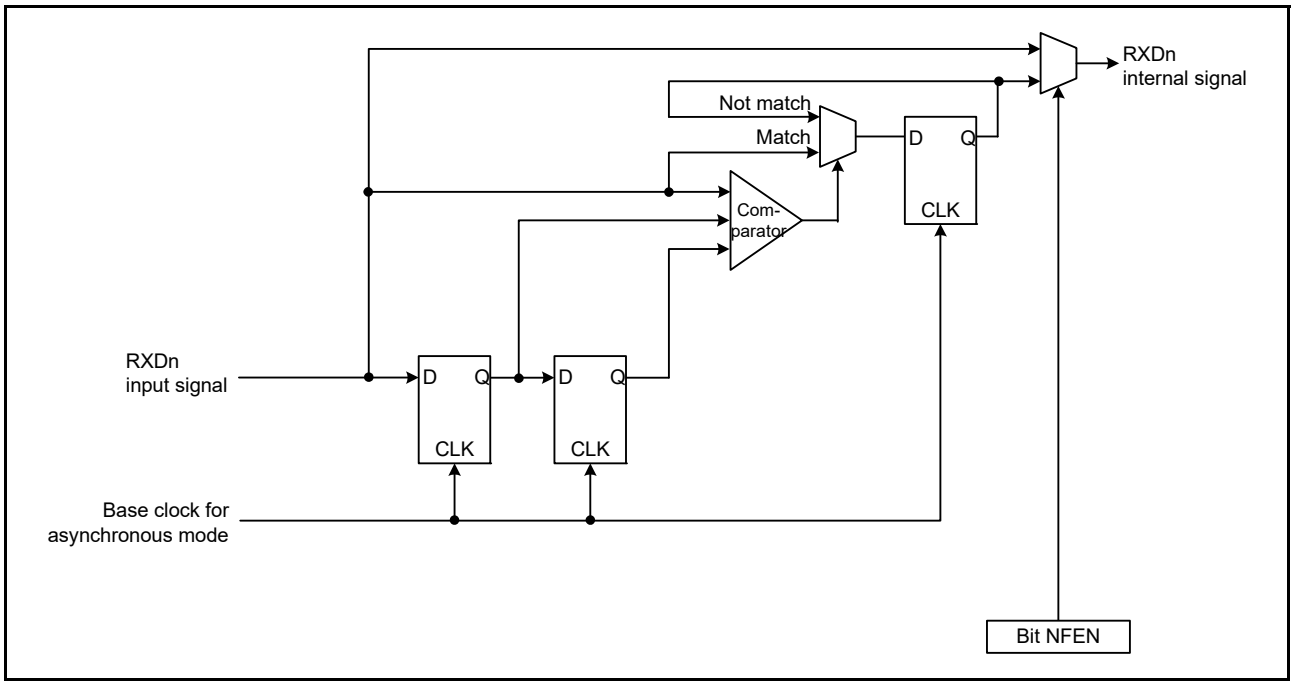

Figure 15.37 Block Diagram of Digital Noise Filter Circuit

15.8 Interrupt Sources

15.8.1 Interrupts in Serial Communications Interface Mode

Table 15.16 lists interrupt sources in serial communication interface mode. Individual interrupt sources can be enabled or disabled with the enable bits in SCR.

If the SCR.TIE bit is 1, a TXI interrupt request is generated when data for transmission are transferred from the TDR to the TSR. A TXI interrupt request can also be generated by setting the SCR.TE bit to 1 after setting the SCR.TIE bit to 1 or by using a single instruction to set the SCR.TE and SCR.TIE bit to 1 at the same time. A TXI interrupt request can activate the DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR.TE bit to 1 while the setting of the SCR.TIE bit is 0 or by setting the SCR.TIE bit to 1 while the setting of the SCR.TE bit is 1.*1

When new data are not written by the time of transmission of the last bit of the current data for transmission and the setting of the SCR.TEIE bit is 1, the SSR.TEND flag becomes 1 and a TEI interrupt request is generated. Furthermore, when the setting of the SCR.TE bit is 1, the SSR.TEND flag retains the value 1 until further data for transmission are written to the TDR, and setting the SCR.TEIE bit to 1 leads to the generation of a TEI interrupt request.

Writing data to the TDR leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the TEI interrupt request.

If the SCR.RIE bit is 1, an RXI interrupt request is generated when received data are stored in the RDR. An RXI interrupt request can activate the DMAC to handle data transfer.

Setting of any from among the ORER, FER, and PER flags in the SSR to 1 while the SCR.RIE bit is 1 leads to the generation of an ERI interrupt request. An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the ERI interrupt request.

Note 1. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmission-completed interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the SCR.TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 15.16 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DMAC Activation
ERI	Receive error	ORER, FER, or PER	Not possible
RXI	Receive data full	—	Possible
TXI	Transmit data empty	—	Possible
TEI	Transmit end	TEND	Not possible

15.8.2 Interrupts in Smart Card Interface Mode

Table 15.17 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 15.17 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DMAC Activation
ERI	Receive error or error signal detection	ORER, PER, or ERS	Not possible
RXI	Receive data full	—	Possible
TXI	Transmit data empty	TEND	Possible

Data transmission/reception using the DMAC is also possible in smart card interface mode. In transmission, when the TEND flag in SSR is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DMAC activation. The TEND flag in SSR is automatically cleared to 0 when the DMAC transfers the data.
If an error occurs, the SCI automatically re-transmits the same data. During the retransmission, the TEND flag in SSR is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the ERS flag in SSR is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag in SSR must be cleared by previously setting the RIE bit in SCR to 1 to enable an ERI interrupt request to be generated at error occurrence.
When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings. For DMAC settings, see section 9, Direct Memory Access Controller.

In reception, an RXI interrupt request is generated when receive data is set to RDR. This RXI interrupt request activates the DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DMAC activation. If an error occurs, the error flag is set. Therefore, the DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

15.9 Usage Notes

15.9.1 Setting the Module Standby Function

SCI operation can be started and stopped by setting the module standby mode. With the value after a reset, SCI operations are stopped. The registers of the modules only become accessible after release from the module standby state. For details, refer to section 42, Power-Down Modes.

15.9.2 Break Detection and Processing

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and so the FER flag in SSR is set to 1 (framing error), and the PER flag in SSR may also be set to 1 (parity error). The SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag in SSR is cleared to 0 (no framing error), it will be set to 1 again.

15.9.3 The Mark State and Production of Breaks

When the SCR.TE bit is 0 (prohibiting serial transmission), setting the general-purpose I/O port makes selection of the level and direction (input or output) of the TXDn pin possible. If this is done, the TXDn pin can be placed in the mark state to send a break at the time of data transmission. Until the SCR.TE bit is set to 1 (permitting serial transmission), the general-purpose I/O port is used to set the TXDn pin to output 1 and set the pin mode to a general-purpose I/O port pin, and thus place the transfer circuit in the mark state (state of having the value 1). On the other hand, to output a break at the time of data transmission, set the TXDn pin to output 0 and make the pin mode settings for a general-purpose I/O port pin. When the SCR.TE bit is set to 0, the transmission section is initialized regardless of the current state of transmission.

15.9.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode Only)

Transmission cannot be started when a receive error flag (ORER) in SSR is set to 1, even if data is written to TDR. Be sure to clear the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be cleared to 0 even if the RE bit in SCR is cleared to 0 (serial reception disabled).

15.9.5 Writing Data to TDR

Data can always be written to TDR. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. Be sure to write transmit data to TDR in the TXI interrupt request processing routine.

15.9.6 Restrictions on Clock Synchronous Transmission

When the external clock source is used as a synchronization clock, update TDR by the DMAC and wait for at least five P1ϕ clock cycles before allowing the transmit clock to be input. If the transmit clock is input within four clock cycles after TDR is updated, the SCI may malfunction.

15.9.7 Restrictions on Using DMAC

When using the DMAC to read RDR, be sure to set the receive end interrupt (RXI) as the activation source of the relevant channel.

15.9.8 Points to Note on Starting Transfer

On the generation of an interrupt request for the interrupt controller at the point where transfer starts, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR.TE or SCR.RE bit to 1).

- Confirm that transfer has stopped (the setting of the SCR.TE or SCR.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR.TIE or SCR.RIE) to 0.
- Read out the corresponding interrupt enable bit (SCR.TIE or SCR.RIE bit) to check that it has actually become 0.
- Clear the interrupt status flag in the interrupt controller to 0.

15.9.9 SCI Operations during Low Power Consumption State

(1) Transmission

When making settings for the module standby state or in transitions to software standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR to 0) after switching the TXDn pin to the general-purpose I/O port pin function. Clearing the TE bit in SCR to 0 resets the TSR and the TEND bit in the SSR. The states of the output pins in the software standby mode depend on the settings for the power-down modes. When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit in SCR to 1, read SSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

Figure 15.38 shows a sample flowchart for transition to software standby mode during transmission.

(2) Reception

Before specifying the module standby state or making a transition to software standby mode, stop the receive operations (RE = 0 in SCR). If transition is made during data reception, the data being received will be invalid.

To receive data in the same reception mode after cancellation of the low power consumption state, set the RE bit in SCR to 1, and then start reception. To receive data in a different reception mode, initialize the SCI first.

Figure 15.39 shows a sample flowchart for transition to software standby mode during reception.

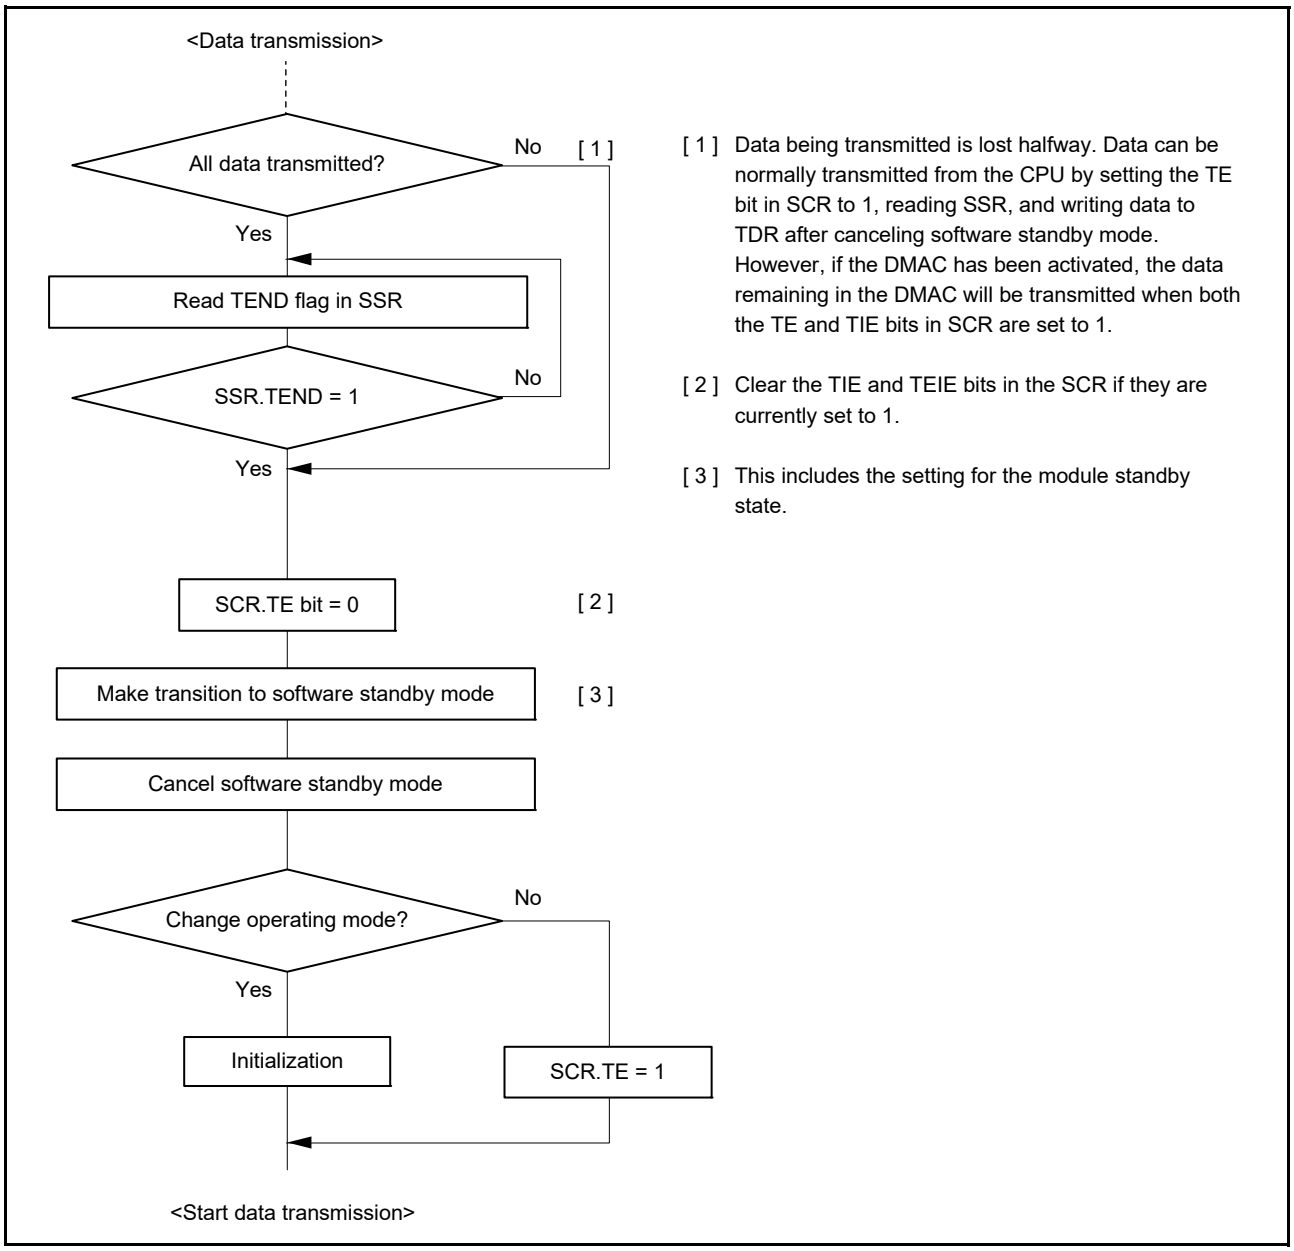

Figure 15.38 Example of Flowchart for Transition to Software Standby Mode during Transmission

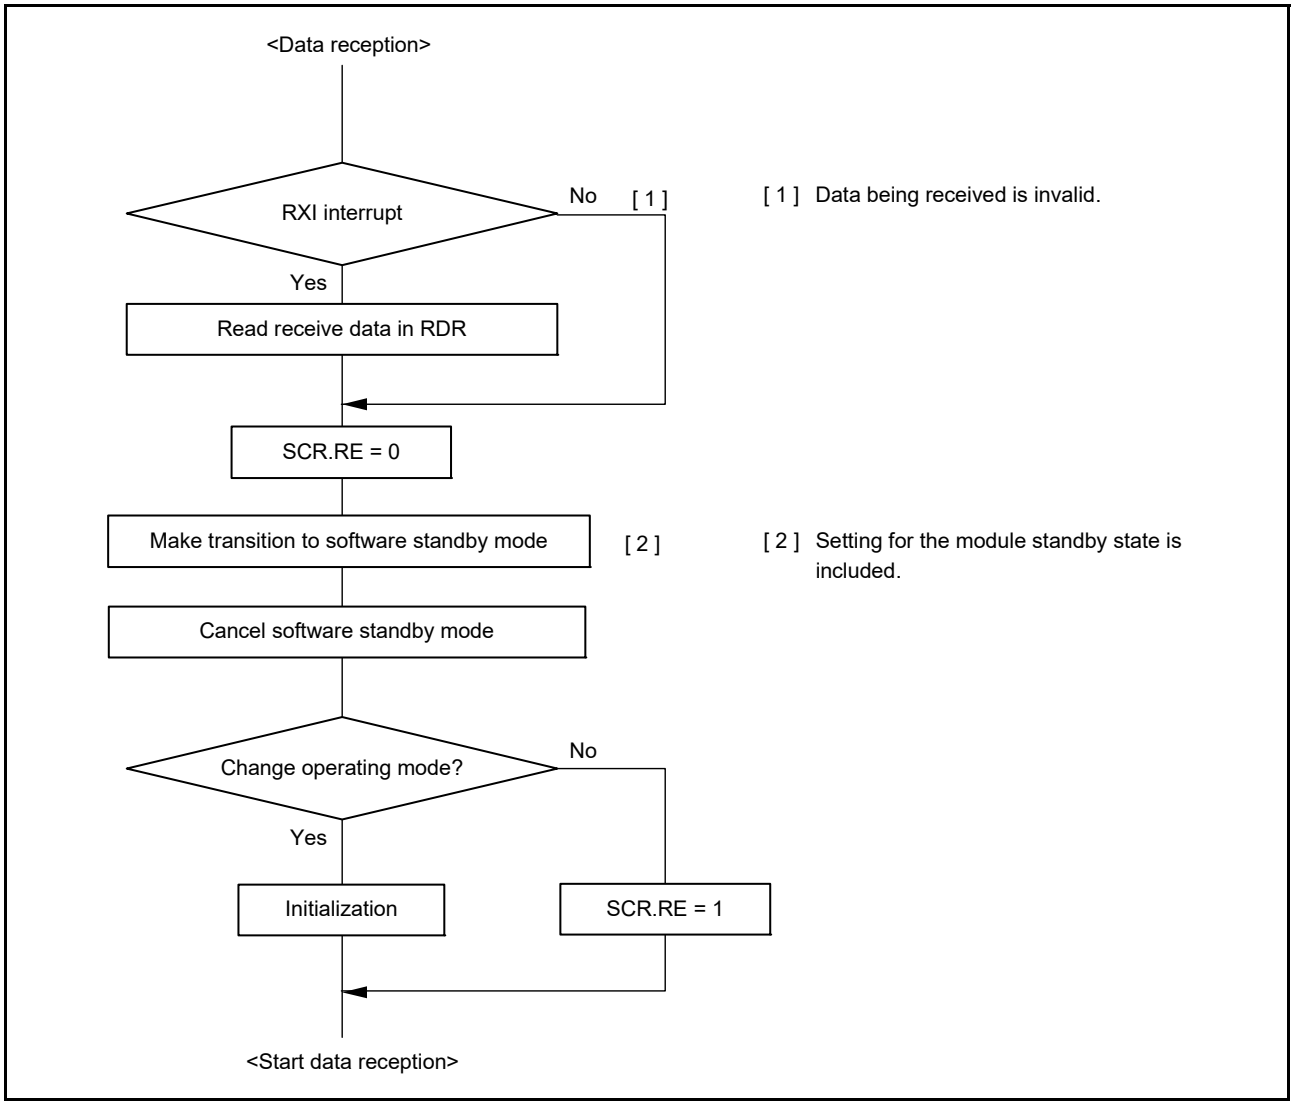

Figure 15.39 Example of Flowchart for Transition to Software Standby Mode during Reception

15.9.10 External Clock Input in Clock Synchronous Mode

In clock synchronous mode, the external clock SCKn must be input as follows:
High-pulse period, low-pulse period = 2 P1ϕ clock cycles or more, period = 6 P1ϕ clock cycles or more

15.10 IrDA Communications

In combination with the on-chip IrDA module, the channel 0 serial communications interface (SCI) transmits and receives waveforms conforming with version 1.0 of the Infrared Data Association (IrDA) standard.
When the IrDA function is enabled by the IRE bit in the IRCR register, the SCI_TXD0 and SCI_RXD0 signals transmitted and received on channel 0 are encoded to and decoded from waveforms conforming with the standard. Connecting these signals to an infrared transceiver enables infrared transmission and reception conforming with the standard.
The standard allows starting communications at a transfer rate of 9600 bps and changing the rate as required. The IrDA module does not have the function of automatically changing the transfer rate. To change the transfer rate of IrDA communications, change the transfer rate of the SCI.

Figure 15.40 shows the block diagram. Table 15.18 shows the pin configuration of the IrDA.

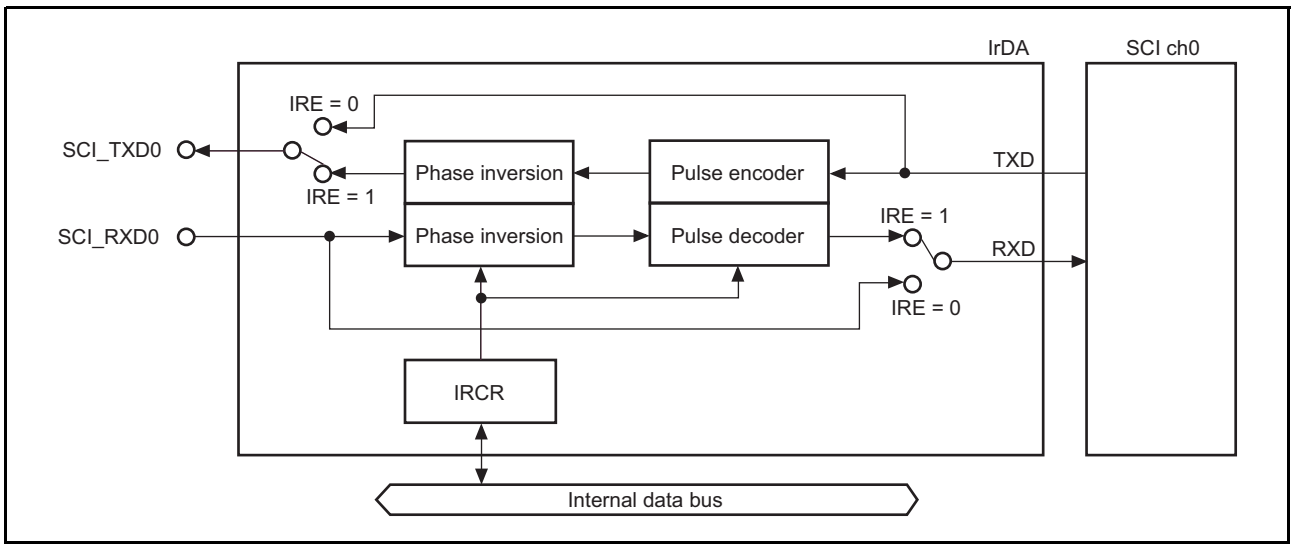

Figure 15.40 Block Diagram

Table 15.18 Pin Configuration

Name	Pin Name	I/O	Description
IrDA transmit data pin	SCI_TXD0	O	IrDA transmit data output
IrDA receive data pin	SCI_RXD0	I	IrDA receive data input

15.11 IrDA Register Description

Table 15.19 shows the register configuration.

Table 15.19 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
IrDA control register	IRCR	R/W	H'00	H'E8014000	8

15.11.1 IrDA Control Register (IRCR)

IRCR is the register which sets the operation of the IrDA module.

Bit:	7	6	5	4	3	2	1	0
	IRE	IRCKS[2:0]			IRTXINV	IRRXINV	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	IRE	0	R/W	IrDA Enable Sets whether the SCI_TXD0 and SCI_RXD0 pins have normal serial function or IrDA function. 0: IrDA function is disabled (The TXD signal transmitted on channel 0 is directly output to the SCI_TXD0 pin) The RXD signal received on channel 0 is directly input to the SCI_RXD0 pin) 1: IrDA function is enabled (The TXD signal transmitted on channel 0 is output to the SCI_TXD0 pin after encoded) The RXD signal received on channel 0 is input to the SCI_RXD0 pin after decoded)
6 to 4	IRCKS[2:0]	000	R/W	IrDA Clock Select Sets the pulse width when the SCI_TXD0 output pulse is encoded with the IRE bit set to 1. 000: B × 3/16 (B = bit rate) 001: P1ϕ/2 010: P1ϕ/4 011: P1ϕ/8 100: P1ϕ/16 101: P1ϕ/32 110: P1ϕ/64 111: P1ϕ/128
3	IRTXINV	0	R/W	SCI_TXD0 Data Sense Switch Sets whether or not to invert the logic levels for SCI_TXD0 output. 0: Data for transmission are directly output to SCI_TXD0. The pulse width set by the IRCKS bits is the width at the high level. 1: Data for transmission are output to SCI_TXD0 after inversion. The pulse width set by the IRCKS bits is the width at the low level.
2	IRRXINV	0	R/W	SCI_RXD0 Data Sense Switch Sets whether or not to invert the logic levels of SCI_RXD0 input. 0: SCI_RXD0 input is directly used as receive data. 1: SCI_RXD0 input is used as receive data after inversion.
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

15.12 IrDA Operation

15.12.1 Flow of IrDA Setting

To set the operation of the IrDA module, follow the procedure below.

1. Make the general-purpose I/O port settings.
2. Set the IRCR register.
3. Set the relevant registers of the SCI.

15.12.2 Transmission

In transmission with the IrDA function enabled, serial data from the TXD pin for the SCI (UART frame data) are converted to IR frames (see Figure 15.41). When the IRTXINV bit is 0 and the value of the serial data is 0, a high-level pulse is output to the SCI_TXD0 pin for three sixteenths of one-bit period (initial value). The width of the high-level pulse can be changed by the IRCKS[2:0] bits in the IRCR register. The IrDA standard stipulates that the high-level pulse width is at least 1.41 µs and no greater than ((3/16 + 2.5%) × bit rate) or ((3/16 × bit rate) + 1.08) µs. When P1ϕ is 66.67 MHz, the width of the high-level pulse can be set from 1.41 µs to 1.92 µs. When the value of a bit of the serial data is 1, no pulse is output.

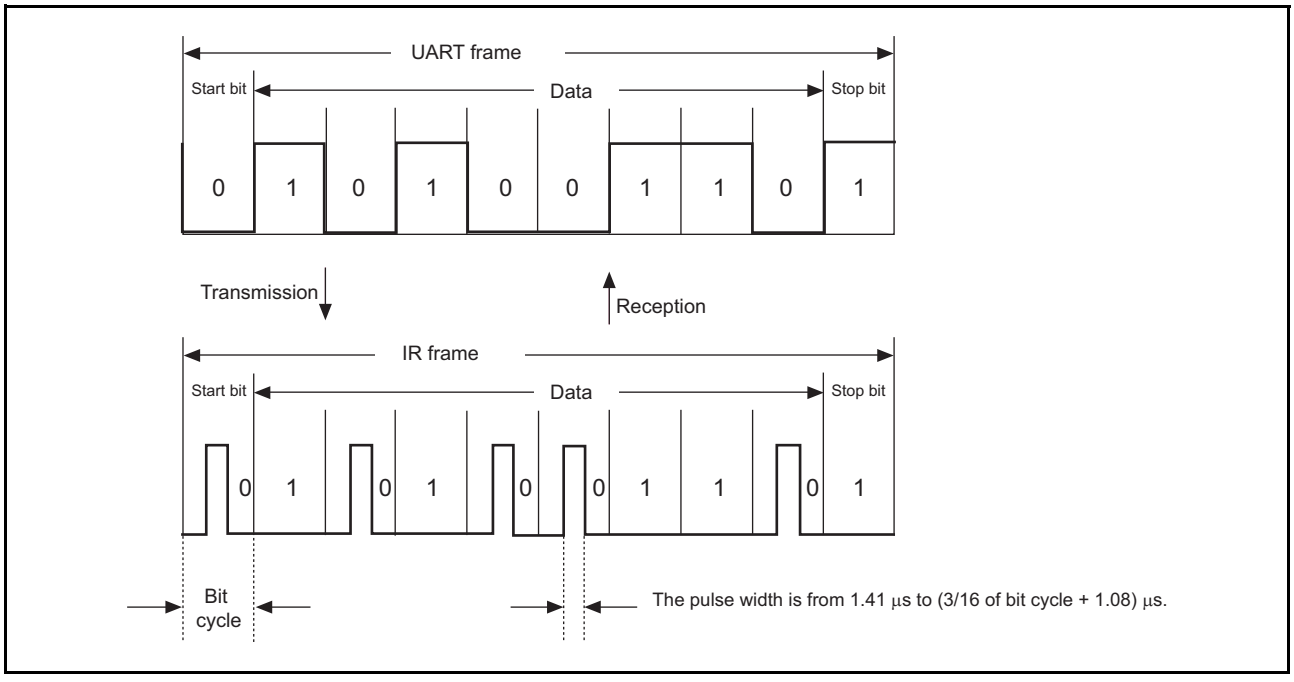

Figure 15.41 Example of IrDA Transmission and Reception

15.12.3 Reception

In reception with the IRDA function enabled, IR frame data from the SCI_RXD0 pin are converted to serial data and output to the RXD pin for the SCI. When the IRRXINV bit is 0, a bit with the value 0 is output on the detection of a high-level pulse. When no pulse is received during one-bit period, a bit with the value 1 is output. Pulses shorter than the lower limit (1.41 µs) are not recognized.

15.12.4 Selection of High-Level Pulse Width

Table 15.20 shows the correspondence between the applicable IRCKS[2:0] bit setting (shortest pulse width), operating frequency P1ϕ, and bit rate when the pulse width is shortened below (bit rate × 3/16) in transmission.

Table 15.20 IRCKS[2:0] Bit Setting

	Bit Rate (bps) (Upper Row) / Bit Cycle × 3/16 (µs) (Lower Row)					
	2400	**9600**	**19200**	**38400**	**57600**	**115200**
P1ϕ (MHz)	**78.13**	**19.53**	**9.77**	**4.88**	**3.26**	**1.63**
50	111	111	111	111	111	—*1
64	111	111	111	111	111	—*2
66.67	111	111	111	111	111	—*2

Note 1. The bit rate cannot be set at the SCI.
Note 2. A pulse width shorter than (bit rate × 3/16) cannot be set.

15.13 Notes on Using the IrDA Module

15.13.1 Shortest Pulse Width in Reception

Pulses shorter than the lower limit (1.41 µs) are not recognized.

15.13.2 Asynchronous Basic Clock for Serial Communication Interface

The IrDA module receives the basic clock with a frequency which is 16 times as high as the communication bit rate from the SCI and operates in combination with the clock. Although one-bit period of the SCI can be set to 16 or 8 clock cycles, the IrDA module supports the SCI that one-bit period is set to 16 clock cycles.

16. Renesas Serial Peripheral Interface

This LSI circuit includes three independent Renesas serial peripheral interfaces.
This module is capable of full-duplex synchronous serial communication.

16.1 Features

This module has the following features.

- SPI transfer functions
  Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows for serial communications through SPI operation (four-wire method).
  Capable of serial communications in master/slave mode
  Supports mode fault error detection (only in SPI slave mode)
  Supports overrun error detection (only in SPI slave mode)
  Switching of the polarity of the serial transfer clock
  Switching of the clock phase of serial transfer
- Data format
  MSB-first/LSB-first selectable
  Transfer bit-length is selectable as 8, 16, or 32 bits.
- Bit rate
  RSPCK can be divided by a maximum of 4096 in master mode
  RSPCK can be generated by dividing P1ϕ by the on-chip baud rate generator.
  An externally input clock can be used as a serial clock.
- Buffer configuration
  8 bytes for transmission and 32 bytes for reception
- SSL control function
  One SSL signal for each channel
  In master mode, outputs SSL signal.
  In slave mode, inputs SSL signal.
  Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay)
  Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
  Controllable delay from RSPCK stoppage to SSL output negation (SSL negation delay)
  Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
  Controllable wait for next-access SSL output assertion (next-access delay)
  Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
  Function for changing SSL polarity
- Control in master transfer
  A transfer of up to four commands can be executed sequentially in looped execution.
  For each command, the following can be set:
  SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, LSB/MSB first, burst, RSPCK delay, SSL negation delay, and next-access delay.
  A transfer can be initiated by writing to the transmit buffer.
  A transfer can be initiated by clearing the SPTEF bit.
  MOSI signal value specifiable in SSL negation
- Interrupt sources
  Maskable interrupt sources:
  Receive interrupt (receive buffer full)
  Transmit interrupt (transmit buffer empty)
  Error interrupt (mode fault, overrun)

- Others
  Provides loop back mode
  Provides a function for disabling (initializing) this module

16.2 Input/Output Pins

Table 16.1 shows the pin configuration. This module automatically switches the input/output direction of the SSL pin. SSL is set as an output in master mode and as an input in slave mode. Pins RSPCK, MOSI, and MISO are automatically set as inputs or outputs according to the setting of master or slave and the level input on SSL (see section 16.4.2, Pin Control).

Table 16.1 Pin Configuration

Channel	Pin Name	Pin Name	I/O	Function
0	Clock pin	RSPCK0	I/O	Clock input/output
	Master transmit data pin	MOSI0	I/O	Master transmit data
	Slave transmit data pin	MISO0	I/O	Slave transmit data
	Slave select 0 pin	SSL00	I/O	Slave selection
1	Clock pin	RSPCK1	I/O	Clock input/output
	Master transmit data pin	MOSI1	I/O	Master transmit data
	Slave transmit data pin	MISO1	I/O	Slave transmit data
	Slave select 0 pin	SSL10	I/O	Slave selection
2	Clock pin	RSPCK2	I/O	Clock input/output
	Master transmit data pin	MOSI2	I/O	Master transmit data
	Slave transmit data pin	MISO2	I/O	Slave transmit data
	Slave select 0 pin	SSL20	I/O	Slave selection

Note: • In the description of the pins, the channel is omitted and pin names are described as RSPCK, MOSI, MISO, and SSL.

16.3 Register Descriptions

Table 16.2 shows the register configuration. These registers enable this module to perform the following controls: specifying master/slave modes, specifying a transfer format, and controlling the transmitter and receiver.

Table 16.2 Register Configuration

Channel	Register Name	Abbreviation*1	R/W	Initial Value	Address	Access Size

Table 16.2 Register Configuration

Channel	Register Name	Abbreviation*1	R/W	Initial Value	Address	Access Size
2	Control register_2	SPCR_2	R/W	H'00	H'E800D800	8
	Slave select polarity register_2	SSLP_2	R/W	H'00	H'E800D801	8
	Pin control register_2	SPPCR_2	R/W	H'00	H'E800D802	8
	Status register_2	SPSR_2	R/(W) *2	H'60	H'E800D803	8
	Data register_2	SPDR_2	R/W	Undefined	H'E800D804	8, 16, 32
	Sequence control register_2	SPSCR_2	R/W	H'00	H'E800D808	8
	Sequence status register_2	SPSSR_2	R	H'00	H'E800D809	8
	Bit rate register_2	SPBR_2	R/W	H'FF	H'E800D80A	8
	Data control register_2	SPDCR_2	R/W	H'20	H'E800D80B	8
	Clock delay register_2	SPCKD_2	R/W	H'00	H'E800D80C	8
	Slave select negation delay register_2	SSLND_2	R/W	H'00	H'E800D80D	8
	Next-access delay register_2	SPND_2	R/W	H'00	H'E800D80E	8
	Command register0_2	SPCMD0_2	R/W	H'070D	H'E800D810	16
	Command register1_2	SPCMD1_2	R/W	H'070D	H'E800D812	16
	Command register2_2	SPCMD2_2	R/W	H'070D	H'E800D814	16
	Command register3_2	SPCMD3_2	R/W	H'070D	H'E800D816	16
	Buffer control register_2	SPBFCR_2	R/W	H'00	H'E800D820	8
	Buffer data count setting register_2	SPBFDR_2	R	H'0000	H'E800D822	16

Note 1. In the description of the register names, the channel is omitted.
Note 2. Only 0 can be written to clear the flag.

16.3.1 Control Register (SPCR)

SPCR sets the operating mode. If the MSTR and MODFEN bits are changed while the function of this module is enabled by setting the SPE bit to 1, subsequent operations cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODFEN	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Function
7	SPRIE	0	R/W	Receive Interrupt Enable Enables or disables generation of receive interrupt requests (SPRI) when the number of receive data units in the receive buffer (SPRX) is equal to or greater than the specified receive buffer data triggering number and the SPRF flag in SPSR is set to 1. 0: Disables the generation of receive interrupt requests. 1: Enables the generation of receive interrupt requests.
6	SPE	0	R/W	Function Enable Setting this bit to 1 enables the module function. When the MODF bit in the status register (SPSR) is 1, the SPE bit cannot be set to 1 (see section 16.4.6, Error Detection). Setting the SPE bit to 0 disables the module function, and initializes a part of the module function (see section 16.4.7, Initialization). 0: Disables the module function. 1: Enables the module function.
5	SPTIE	0	R/W	Transmit Interrupt Enable Enables or disables generation of transmit interrupt requests (SPTI) when the number of transmit data units in the transmit buffer (SPTX) is equal to or less than the specified transmit buffer data triggering number and the SPTEF flag in SPSR is set to 1. 0: Disables the generation of transmit interrupt requests. 1: Enables the generation of transmit interrupt requests.
4	SPEIE	0	R/W	Error Interrupt Enable Enables or disables the generation of error interrupt requests when this module detects a mode fault error and sets the MODF bit in the status register (SPSR) to 1, or when this module detects an overrun error and sets the OVRF bit in SPSR to 1 (see section 16.4.6, Error Detection). 0: Disables the generation of error interrupt requests. 1: Enables the generation of error interrupt requests. Note: This bit is valid only in SPI slave mode.
3	MSTR	0	R/W	Master/Slave Mode Select Selects master/slave mode. According to MSTR bit settings, this module determines the direction of the RSPCK, MOSI, MISO, and SSL pins. 0: Slave mode 1: Master mode
2	MODFEN	0	R/W	Mode Fault Error Detection Enable Enables or disables the detection of a mode fault error (see section 16.4.6, Error Detection). 0: Disables the detection of a mode fault error. 1: Enables the detection of a mode fault error. Note: This bit is valid only in SPI slave mode. When master mode is specified with the MSTR bit, this bit should always be cleared to 0.
1, 0	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

16.3.2 Slave Select Polarity Register (SSLP)

SSLP sets the polarity of the SSL signal. If the contents of SSL0P are changed while the function of this module is enabled by setting the SPE bit in the control register (SPCR) to 1, subsequent operations cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SSL0P
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Function
7 to 1	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
0	SSL0P	0	R/W	SSL Signal Polarity Setting Sets the polarity of the SSL signal. The value of SSL0P indicates the active polarity of the SSL signal. 0: SSL signal 0-active 1: SSL signal 1-active

16.3.3 Pin Control Register (SPPCR)

SPPCR sets the modes of the pins. If the contents of this register are changed while the function of this module is enabled by setting the SPE bit in the control register (SPCR) to 1, subsequent operations cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	MOIFE	MOIFV	—	—	—	SPLP
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Function
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5	MOIFE	0	R/W	MOSI Idle Value Fixing Enable Fixes the MOSI output value when this module in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When MOIFE is 0, this module outputs the last output value from the previous serial transfer during the SSL negation period to the MOSI pin. (The value is undefined when CPHA is 0). When MOIFE is 1, this module outputs the fixed value set in the MOIFV bit to the MOSI pin. 0: MOSI output value equals the last output value from previous transfer. (The value is undefined when CPHA is 0). 1: MOSI output value equals the value set in the MOIFV bit.
4	MOIFV	0	R/W	MOSI Idle Fixed Value If the MOIFE bit is 1 in master mode, this module, according to MOIFV bit settings, determines the MOSI signal value during the SSL negation period (including the SSL retention period during a burst transfer). 0: MOSI Idle fixed value equals 0. 1: MOSI Idle fixed value equals 1.
3 to 1	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
0	SPLP	0	R/W	Loopback When the SPLP bit is set to 1, this module shuts off the path between the MISO pin and the shift register, and between the MOSI pin and the shift register, and connects (reverses) the input path and the output path for the shift register. 0: Normal mode 1: Loopback mode

16.3.4 Status Register (SPSR)

SPSR indicates the operating status.

Bit:	7	6	5	4	3	2	1	0
	SPRF	TEND	SPTEF	—	—	MODF	—	OVRF
Initial value:	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R/(W)*	R	R/(W)*

Note: * Only 0 can be written to clear the flag after reading 1.

Bit	Bit Name	Initial Value	R/W	Function
7	SPRF	0	R	Receive Buffer Full Flag Indicates that the number of receive data units in the receive buffer (SPRX) is equal to or greater than the receive buffer data triggering number specified in the buffer control register (SPBFCR). 0: The number of receive data units in the receive buffer is less than the receive buffer data triggering number. 1: The number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number. [Clearing conditions] • The receive buffer data is read until the number of data units in the receive buffer becomes less than the specified receive buffer data triggering number. • Receive buffer data reset is enabled. • Power-on reset [Setting condition] • The number of data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number.
6	TEND	1	R	Transmit End This bit is set to 1 when transmission is completed, and this bit is 0 when transmission is not completed. [Clearing condition] • When transmit data are transferred from the transmit register to the shift register. [Setting condition] • When the number of data units in the transmit buffer (SPTX) is zero when a serial transfer is completed. Note: This bit is valid only in SPI master mode.
5	SPTEF	1	R	Transmit Buffer Empty Flag Indicates that the number of transmit data units in the transmit buffer (SPTX) is equal to or less than the transmit buffer data triggering number specified in the buffer control register (SPBFCR). 0: The number of transmit data units in the transmit buffer is equal to or greater than the specified transmit buffer data triggering number. 1: The number of transmit data units in the transmit buffer is less than the specified transmit buffer data triggering number. [Clearing condition] • When data is written to the transmit buffer until the number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number. [Setting conditions] • When the number of transmit data units in the transmit buffer is less than the specified transmit buffer data triggering number. • When transmit buffer data reset is enabled. • Power-on reset
4, 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Function
2	MODF	0	R/(W)*1	Mode Fault Error Flag Indicates the occurrence of a mode fault error. If the MODFEN bit is set to 1 when this module is in slave mode and the SSL pin is negated before the RSPCK cycle necessary for data transfer ends, this module detects a mode fault error. The active level of the SSL signal is determined by the SSL0P bit in the slave select polarity register (SSLP). [Clearing conditions] • SPSR is read when the MODF bit is 1, and then 0 is written to the MODF bit. • Power-on reset 0: No mode fault error occurred 1: A mode fault error occurred Note: This bit is valid only in SPI slave mode.
1	—	0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
0	OVRF	0	R/(W)*1	Overrun Error Flag Indicates the occurrence of an overrun error. If a serial transfer ends when there is not enough space for receiving the specified length of data in the receive buffer (SPRX), this module detects an overrun error, and sets the OVRF bit to 1. [Clearing conditions] • SPSR is read when the OVRF bit is 1, and then 0 is written to the OVRF bit. • Power-on reset 0: No overrun error occurred 1: An overrun error occurred Note: This bit is valid only in SPI slave mode.

Note 1. Only 0 can be written to clear the flag after reading 1.

16.3.5 Data Register (SPDR)

SPDR is a buffer that holds data for transmission and reception.
The transmit buffer (SPTX) and receive buffer (SPRX) are independent and are mapped to SPDR.
SPDR should be read or written to in byte, word, or longword units according to the access width specification bit (SPLW) in the data control register (SPDCR).
The bit length to be used is determined by the data length specification bits (SPB3 to SPB0) in the command register (SPCMD).
The access width set by SPDCR must agree with the data length set by SPCMD.
When data is written to SPDR, the data will be written to the transmit buffer from SPDR if the transmit buffer has a space equal to or more than the SPDR access width. If there is not enough space, data will not be written to the transmit buffer. Even if an attempt is made to write data to the buffer, the data is ignored.
When data is read from SPDR, receive data in the receive buffer will be read. If SPDR is read when there is no receive data in the receive buffer, the read value is undefined.
When SPDR is written to with the longword-, word-, or byte-access width, the transmit data should be written to address 0 irrespective of the access width. If data is written to the other addresses, the data is not guaranteed.
When SPDR is read with the longword-, word-, or byte-access width, the receive data should be read from address 0. If data is read from the other addresses, the data is not guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPD31	SPD30	SPD29	SPD28	SPD27	SPD26	SPD25	SPD24	SPD23	SPD22	SPD21	SPD20	SPD19	SPD18	SPD17	SPD16
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPD15	SPD14	SPD13	SPD12	SPD11	SPD10	SPD9	SPD8	SPD7	SPD6	SPD5	SPD4	SPD3	SPD2	SPD1	SPD0
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

16.3.6 Sequence Control Register (SPSCR)

SPSCR sets the sequence control method when this module operates in master mode. If the contents of SPSCR are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SPSLN1	SPSLN0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
7 to 2	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1 0	SPSLN1 SPSLN0	0 0	R/W R/W	Sequence Length Specification These bits specify a sequence length when this module in master mode performs sequential operations. This module in master mode changes command registers 0 to 3 (SPCMD0 to SPCMD3) to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN1 and SPSLN0 bits. The relationship among the setting of bits SPSLN1 and SPSLN0, sequence length, and SPCMD0 to SPCMD3 referenced by this module is shown below. In slave mode, SPCMD0 is always referenced. Sequence Length / Referenced SPCMD # 00: 1 — 0 → 0 → … 01: 2 — 0 → 1 → 0 → … 10: 3 — 0 → 1 → 2 → 0 → … 11: 4 — 0 → 1 → 2 → 3 → 0 → …

16.3.7 Sequence Status Register (SPSSR)

SPSSR indicates the sequence control status when this module operates in master mode.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SPCP1	SPCP0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Function
7 to 2	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1	SPCP1	0	R	Command Pointer During sequence control, these bits indicate one of the command registers 0 to 3 (SPCMD0 to SPCMD3) that is currently pointed to by the pointer. The relationship between the setting of SPCP1 and SPCP0 and SPCMD0 to SPCMD3 is shown below. For the sequence control, see section 16.4.8 (1) (c), Sequence Control. 00: SPCMD0 01: SPCMD1 10: SPCMD2 11: SPCMD3
0	SPCP0	0	R	

16.3.8 Bit Rate Register (SPBR)

SPBR sets the bit rate in master mode. If the contents of SPBR are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	SPR7	SPR6	SPR5	SPR4	SPR3	SPR2	SPR1	SPR0
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When this module is used in slave mode, the bit rate depends on the bit rate of the input clock regardless of the settings of SPBR and BRDV.

The bit rate is determined by combinations of SPBR settings and the bit settings in the BRDV1 and BRDV0 bits in the command registers (SPCMD0 to SPCMD3). The equation for calculating the bit rate is given below. In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV1 and BRDV0 bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(P1\phi)}{2 \times (n + 1) \times 2^{N}}$$

Table 16.3 shows examples of the relationship between the SPBR register and BRDV1 and BRDV0 bit settings.

Table 16.3 Relationship between SPBR and BRDV1 and BRDV0 Settings

			Bit Rate		
SPBR (n)	**BRDV[1:0] (N)**	**Division Ratio**	**P1φ = 50 MHz**	**P1φ = 64 MHz**	**P1φ = 66.67 MHz**
0	0	2*1	25.00 Mbps	32.00 Mbps	33.33 Mbps
1	0	4	12.50 Mbps	16.00 Mbps	16.67 Mbps
2	0	6	8.33 Mbps	10.67 Mbps	11.11 Mbps
3	0	8	6.25 Mbps	8.00 Mbps	8.33 Mbps
4	0	10	5.00 Mbps	6.40 Mbps	6.67 Mbps
5	0	12	4.17 Mbps	5.33 Mbps	5.56 Mbps
5	1	24	2.08 Mbps	2.67 Mbps	2.78 Mbps
5	2	48	1.04 Mbps	1.33 Mbps	1.39 Mbps
5	3	96	520.83 Kbps	666.67 Kbps	694.44 Kbps
255	3	4096	12.21 Kbps	15.63 Kbps	16.28 Kbps

Note 1. Examine the timing specifications to determine the bit rate in the actual system.

16.3.9 Data Control Register (SPDCR)

SPDCR selects the width to access SPDR from longword-, word-, and byte-width, and enables or disables dummy data transmission for the master mode operation.

If the contents of SPDCR are changed while bit TEND in the status register (SPSR) indicates that transmission is not completed, the subsequent operation cannot be guaranteed.

Bit:	7	6	5	4	3	2	1	0
	TXDMY	SPLW1	SPLW0	—	—	—	—	—
Initial value:	0	0	1	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R

Bit	**Bit Name**	**Initial Value**	**R/W**	**Function**
7	TXDMY	0	R/W	Dummy Data Transmission Enable Enables or disables dummy data transmission. When communication is performed with this bit set to 1, dummy data is transmitted from the MOSI pin and a serial communication can be performed even if there is no transmit data in the transmit buffer. Specifically, if there is no transmit data in the transmit buffer and this bit is set to 1, dummy data is transferred to the shift register. Data previously transmitted from the pin is used as dummy data. If this bit is set to 1 after the initialization and a transfer is performed, the transmitted dummy data is undefined. 0: Disables dummy data transmission. 1: Enables dummy data transmission. Note: This bit is valid only in the master mode.
6 5	SPLW1 SPLW0	0 1	R/W R/W	Access Width Specification Specifies the width for accessing the data register (SPDR). If the length of data transferred to SPDR does not agree with these bit settings, operation is not guaranteed.* 00: Setting prohibited 01: SPDR is accessed in bytes (8 bits). 10: SPDR is accessed in words (16 bits). 11: SPDR is accessed in longwords (32 bits).
4 to 0	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

Note: * The data length is specified by the SPB3 to SPB0 bits in the command register (SPCMD).

See section 16.3.5, Data Register (SPDR).

16.3.10 Clock Delay Register (SPCKD)

SPCKD sets a period from the beginning of SSL signal assertion to RSPCK oscillation (RSPCK delay) when the SCKDEN bit in the command register (SPCMD) is 1. If the contents of SPCKD are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.
When using this module in slave mode, set B'000 to SCKDL2 to SCKDL0.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCKDL2	SCKDL1	SCKDL0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 1 0	SCKDL2 SCKDL1 SCKDL0	0 0 0	R/W R/W R/W	RSPCK Delay Setting These bits set an RSPCK delay value when the SCKDEN bit in SPCMD is 1. The relationship between the setting of SCKDL2 to SCKDL0 and the RSPCK delay value is shown below. 000: 1 RSPCK 001: 2 RSPCK 010: 3 RSPCK 011: 4 RSPCK 100: 5 RSPCK 101: 6 RSPCK 110: 7 RSPCK 111: 8 RSPCK

16.3.11 Slave Select Negation Delay Register (SSLND)

SSLND sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSL signal during a serial transfer by this module in master mode. If the contents of SSLND are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

When using this module in slave mode, set B'000 to SLNDL2 to SLNDL0.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SLNDL2	SLNDL1	SLNDL0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 1 0	SLNDL2 SLNDL1 SLNDL0	0 0 0	R/W R/W R/W	SSL Negation Delay Setting These bits set an SSL negation delay when the SLNDEN bit in SPCMD is 1. The relationship between the setting of SLNDL2 to SLNDL0 and the SSL negation delay value is shown below. 000: 1 RSPCK 001: 2 RSPCK 010: 3 RSPCK 011: 4 RSPCK 100: 5 RSPCK 101: 6 RSPCK 110: 7 RSPCK 111: 8 RSPCK

16.3.12 Next-Access Delay Register (SPND)

SPND sets a non-active period (next-access delay) after termination of a serial transfer when the SPNDEN bit in the command register (SPCMD) is 1. If the contents of SPND are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

When using this module in slave mode, set B'000 to SPNDL2 to SPNDL0.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	SPNDL2	SPNDL1	SPNDL0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2	SPNDL2	0	R/W	Next-Access Delay Setting These bits set a next-access delay when the SPNDEN bit in SPCMD is 1. The relationship between the setting of SPNDL2 to SPNDL0 and the next-access delay value is shown below. 000: 1 RSPCK + 2 P1ϕ 001: 2 RSPCK + 2 P1ϕ 010: 3 RSPCK + 2 P1ϕ 011: 4 RSPCK + 2 P1ϕ 100: 5 RSPCK + 2 P1ϕ 101: 6 RSPCK + 2 P1ϕ 110: 7 RSPCK + 2 P1ϕ 111: 8 RSPCK + 2 P1ϕ
1	SPNDL1	0	R/W	
0	SPNDL0	0	R/W	

16.3.13 Command Register (SPCMD)

Each channel has four command registers (SPCMD0 to SPCMD3). SPCMD0 to SPCMD3 are used to set a transfer format for master mode operation. Some of the bits in SPCMD0 are used to set a transfer mode for slave mode operation. In master mode, this module sequentially references SPCMD0 to SPCMD3 according to the settings in bits SPSLN1 and SPSLN0 in the sequence control register (SPSCR), and executes the serial transfer that is set in the referenced SPCMD. While bit TEND in the status register (SPSR) indicates that transmission is not completed, correct operation of this module cannot be guaranteed if SPCMD is changed that is referred by this module. SPCMD referenced by this module in master mode can be checked by means of bits SPCP1 and SPCP0 in the sequence status register (SPSSR). When the function of this module in slave mode is enabled, operation cannot be guaranteed if the value set in SPCMD0 is changed.

Bit:	15	14	13	12	11	10	9	8
	SCKDEN	SLNDEN	SPNDEN	LSBF	SPB3	SPB2	SPB1	SPB0
Initial value:	0	0	0	0	0	1	1	1

Initial value:	0	0	0	0	1	1	0	1
R/W:	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
15	SCKDEN	0	R/W	RSPCK Delay Setting Enable Sets the period from the point this module in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay). If the SCKDEN bit is 0, this module sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, this module starts the oscillation of RSPCK at an RSPCK delay in compliance with the clock delay register (SPCKD) settings. To use this module in slave mode, the SCKDEN bit should be set to 0. 0: An RSPCK delay of 1 RSPCK 1: An RSPCK delay equal to SPCKD settings.
14	SLNDEN	0	R/W	SSL Negation Delay Setting Enable Sets the period from the point this module in master mode stops RSPCK oscillation until this module sets the SSL signal inactive (SSL negation delay). If the SLNDEN bit is 0, this module sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, this module negates the SSL signal at an SSL negation delay in compliance with the slave select negation delay register (SSLND) settings. To use this module in slave mode, the SLNDEN bit should be set to 0. 0: An SSL negation delay of 1 RSPCK 1: An SSL negation delay equal to SSLND settings.
13	SPNDEN	0	R/W	Next-Access Delay Enable Sets the period from the point this module in master mode terminates a serial transfer and sets the SSL signal inactive until this module enables the SSL signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, this module sets the next-access delay to 1 RSPCK + 2P1ϕ. If the SPNDEN bit is 1, this module inserts a next-access delay in compliance with the next-access delay register (SPND) settings. To use this module in slave mode, the SPNDEN bit should be set to 0. 0: A next-access delay of 1 RSPCK + 2 P1ϕ 1: A next-access delay equal to SPND settings.
12	LSBF	0	R/W	LSB First Sets the data format in master mode or slave mode to MSB first or LSB first. 0: MSB first 1: LSB first

Bit	Bit Name	Initial Value	R/W	Function
11 10 9 8	SPB3 SPB2 SPB1 SPB0	0 1 1 1	R/W R/W R/W R/W	Data Length Setting These bits set a transfer data length in master mode or slave mode. 0100 to 0111: 8 bits 1111: 16 bits 0010, 0011: 32 bits Others: Setting prohibited
7	SSLKP	0	R/W	SSL Signal Level Keeping When this module in master mode performs a serial transfer, this bit specifies whether the SSL signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command. To use this module in slave mode, the SSLKP bit should be set to 0. 0: Negates the SSL signal upon completion of transfer. 1: Keeps the SSL signal level from the end of the transfer until the beginning of the next access.
6 to 4	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
3 2	BRDV1 BRDV0	1 1	R/W R/W	Bit Rate Division Setting These bits are used to determine the bit rate. A bit rate is determined by combinations of bits BRDV1 and BRDV 0 and the settings in the bit rate register (SPBR) (see section 16.3.8, Bit Rate Register (SPBR)). The settings in SPBR determine the base bit rate. The settings in bits BRDV1 and BRDV0 are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the bits SPCMD0 to SPCMD3, different BRDV1 and BRDV0 settings can be specified. This permits the execution of serial transfers at a different bit rate for each command. 00: Select the base bit rate. 01: Select the base bit rate divided by 2. 10: Select the base bit rate divided by 4. 11: Select the base bit rate divided by 8.
1	CPOL	0	R/W	RSPCK Polarity Setting Sets an RSPCK polarity in master or slave mode. When data communication is performed between the Renesas serial peripheral interface module and the other modules, the same RSPCK polarity should be set for both modules. 0: RSPCK = 0 when idle 1: RSPCK = 1 when idle
0	CPHA	1	R/W	RSPCK Phase Setting Sets an RSPCK phase in master or slave mode. When data communication is performed between the Renesas serial peripheral interface module and the other modules, the same RSPCK phase should be set for both modules. 0: Data sampling on odd edge, data variation on even edge 1: Data variation on odd edge, data sampling on even edge

16.3.14 Buffer Control Register (SPBFCR)

SPBFCR resets the number of data units in the transmit buffer (SPTX) or receive buffer (SPRX) and sets the number of triggering data units.

Bit:	7	6	5	4	3	2	1	0
	TXRST	RXRST	TXTRG[1:0]		—	RXTRG[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Function
7	TXRST	0	R/W	Transmit Buffer Data Reset Resets the transmit buffer to an empty state. Transmit data in the transmit buffer becomes invalid when this bit is set to 1. 0: Disables the reset operation*. 1: Enables the reset operation Note: The reset operation is performed after a power-on reset.
6	RXRST	0	R/W	Receive Buffer Data Reset Resets the receive buffer to an empty state. Receive data in the receive buffer becomes invalid when this bit is set to 1. 0: Disables the reset operation*. 1: Enables the reset operation Note: The reset operation is performed after a power-on reset.
5, 4	TXTRG[1:0]	00	R/W	Transmit Buffer Data Triggering Number Specifies the timing at which the transmit buffer empty state is determined, that is when the SPTEF flag in the status register is set. When the number of bytes of data in the transmit buffer (SPTX) is equal to or less than the specified triggering number, the SPTEF flag is set to 1. 00: 7 bytes (1)* 01: 6 bytes (2)* 10: 4 bytes (4)* 11: 0 bytes (8)* Note: The value in the parenthesis shows the number of available bytes in the transmit buffer (SPTX).
3	—	0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	RXTRG[2:0]	000	R/W	Receive Buffer Data Triggering Number Specifies the timing at which the receive buffer full state is determined, that is when the SPRF flag in the status register is set. When the number of bytes of data in the receive buffer (SPRX) is equal to or greater than the specified triggering number, the SPRF flag is set to 1. 000: 1 byte (31)* 001: 2 bytes (30)* 010: 4 bytes (28)* 011: 8 bytes (24)* 100: 16 bytes (16)* 101: 24 bytes (8)* 110: 32 bytes (0)* 111: 5 bytes (27)* Note: * The value in the parenthesis shows the number of available bytes in the receive buffer (SPRX).

16.3.15 Buffer Data Count Setting Register (SPBFDR)

SPBFDR indicates the number of data units stored in the transmit buffer (SPTX) and receive buffer (SPRX). The upper eight bits indicate the number of transmit data units in SPTX and the lower eight bits indicate the number of receive data units in SPRX.

Bit:	15	14	13	12	11	10	9	8
	—	—	—	—	T[3:0]			
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	7	6	5	4	3	2	1	0
	—	—	R[5:0]					
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Function
15 to 12	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
11 to 8	T[3:0]	0000	R	Indicates the number of bytes of data to be transmitted in SPTX. B'0000 indicates that SPTX is empty. B'1000 indicates that SPTX is full.
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5 to 0	R[5:0]	000000	R	Shows the number of bytes of received data in SPTX. B'000000 indicates that SPRX is empty. B'100000 indicates that SPRX is full.

16.4 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

16.4.1 Overview of Operations

This module is capable of serial transfers in slave mode and master mode. A particular mode of this module can be selected by using the MSTR bit in the control register (SPCR). Table 16.4 gives the relationship between the modes and SPCR settings, and a description of each mode.

Table 16.4 Relationship between Modes and SPCR and Description of Each Mode

Mode	Slave (SPI Operation)	Master (SPI Operation)
MSTR bit setting	0	1
MODFEN bit setting	0 or 1	0
RSPCK signal	Input	Output
MOSI signal	Input	Output
MISO signal	Output/Hi-Z	Input
SSL signal	Input	Output
SSL polarity modification function	Supported	Supported
Transfer rate	Up to P1ϕ/8	Up to P1ϕ/2
Clock source	RSPCK input	On-chip baud rate generator
Clock polarity	Two	Two
Clock phase	Two	Two
First transfer bit	MSB/LSB	MSB/LSB
Transfer data length	8, 16, or 32 bits	8, 16, or 32 bits
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)
RSPCK delay control	Not supported	Supported
SSL negation delay control	Not supported	Supported
Next-access delay control	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written when SPE = 1
Sequence control	Not supported	Supported
Transmit buffer empty detection	Supported	Supported
Receive buffer full detection	Supported	Supported
Overrun error detection	Supported	Not Supported
Mode fault error detection	Supported (MODFEN = 1)	Not supported

16.4.2 Pin Control

According to the MSTR bit in the control register (SPCR), this module can automatically switch pin directions and output modes. Table 16.5 shows the relationship between pin states and bit settings.

Table 16.5 Relationship between Pin States and Bit Settings

Mode	Pin	Pin State*1
Master mode (SPI operation) (MSTR = 1)	RSPCK	CMOS output
	SSL	CMOS output
	MOSI	CMOS output
	MISO	Input
Slave mode (SPI operation) (MSTR = 0)	RSPCK	Input
	SSL	Input
	MOSI	Input
	MISO*1	CMOS output/Hi-Z

Note 1. When SSL is at the non-active level or the SPE bit in SPCR is cleared to 0, the pin state is Hi-Z.

This module in master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as shown in Table 16.6.

Table 16.6 MOSI Signal Value Determination during SSL Negation Period

MOIFE	MOIFV	MOSI Signal Value during SSL Negation Period
0	0, 1	Last output value from previous transfer (The value is undefined when CPHA is 0)
1	0	Always 0
1	1	Always 1

16.4.3 System Configuration Example

(1) Master/Slave (with This LSI Acting as Master)

Figure 16.2 shows a master/slave system configuration example when this LSI is used as a master. In master/slave configuration, the SSL output of this LSI (master) is not used. The SSL input of the slave is fixed to the low level, and the slave is always maintained in a selected state. In the transfer format corresponding to the case where the CPHA bit in the control register (SPCR) is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSL output of this LSI should be connected to the SSL input of the slave device.
This LSI (master) always drives the RSPCK and MOSI. The slave always drives the MISO.

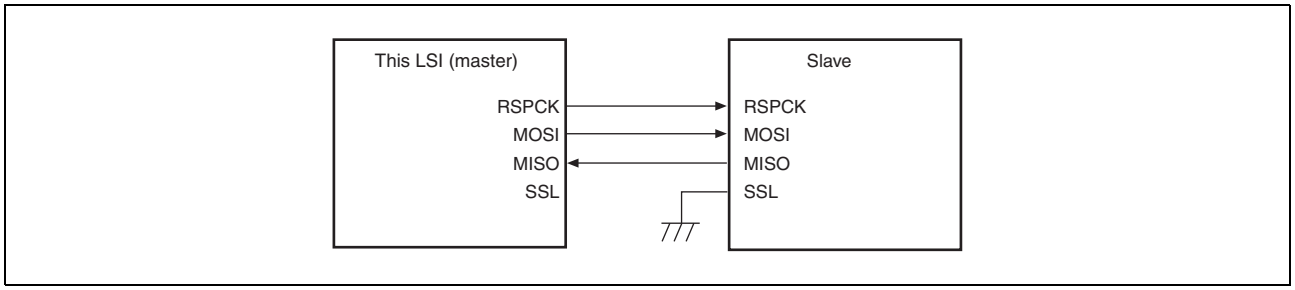

Figure 16.2 Master/Slave Configuration Example (This LSI = Master)

(2) Master/Slave (with This LSI Acting as Slave)

Figure 16.3 shows a master/slave system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave, the SSL pin is used as SSL input. The master always drives the RSPCK and MOSI. This LSI (slave) always drives the MISO. When SSL is at the non-active level, the pin state is Hi-Z.

In the slave configuration in which the CPHA bit in the command register (SPCMD) is set to 1, the SSL input of this LSI (slave) is fixed to the 0 level, this LSI (slave) is always maintained in a selected state, and in this manner it is possible to execute serial transfer (Figure 16.4).

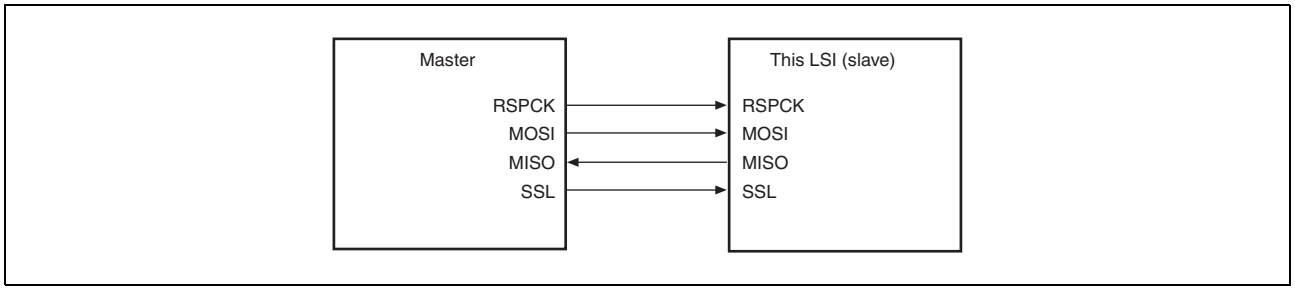

Figure 16.3 Master/Slave Configuration Example (This LSI = Slave)

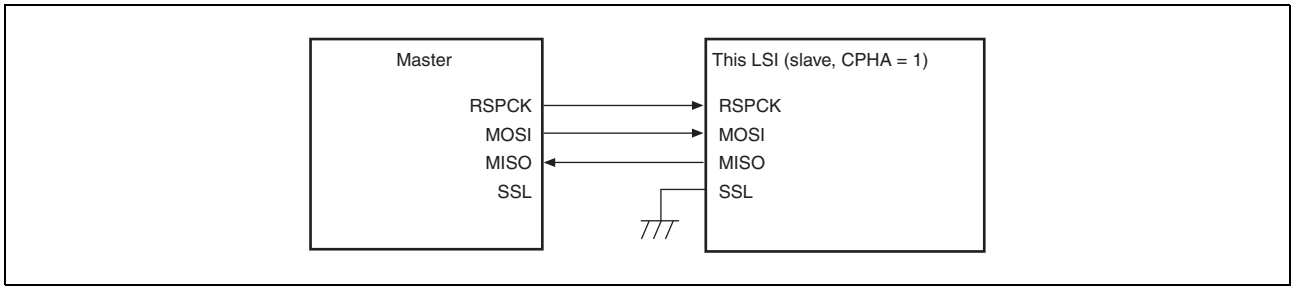

Figure 16.4 Master/Slave Configuration Example (This LSI = Slave, CPHA = 1)

(3) Master/Multi-Slave (with This LSI Acting as Slave)

Figure 16.5 shows a master/multi-slave system configuration example when this LSI is used as a slave. In the example of Figure 16.5, the system is comprised of a master and two LSIs (slave X and slave Y).
The RSPCK and MOSI outputs of the master are connected to the RSPCK and MOSI inputs of the LSIs (slave X and slave Y). The MISO outputs of the LSIs (slave X and slave Y) are all connected to the MISO input of the master. SSLX and SSLY outputs of the master are connected to the SSL inputs of the LSIs (slave X and slave Y), respectively.
The master always drives RSPCK, MOSI, SSLX, and SSLY. Of the LSIs (slave X and slave Y), the slave that receives low level input into the SSL0 input drives MISO.

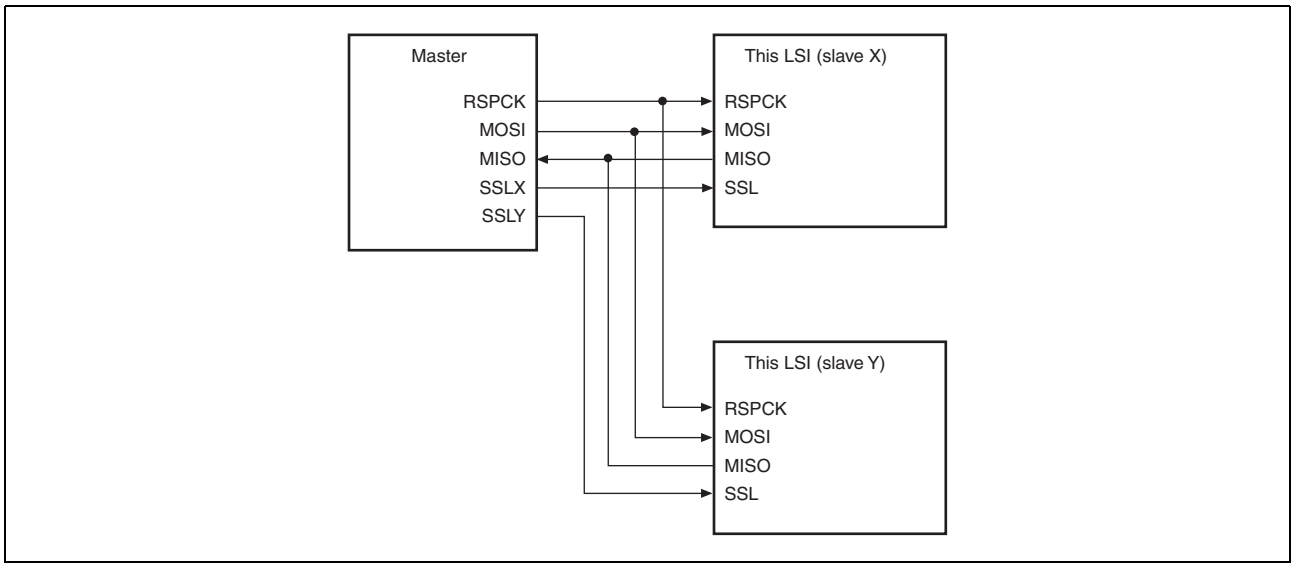

Figure 16.5 Master/Multi-Slave Configuration Example (This LSI = Slave)

16.4.4 Transfer Format

(1) CPHA = 0

Figure 16.6 shows a sample transfer format for the serial transfer of 8-bit data when the CPHA bit in the command register (SPCMD) is 0. In Figure 16.6, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which this module fetches serial transfer data into the shift register. The input/output directions of the signals depend on the settings of this module. For details, see section 16.4.2, Pin Control.

When the CPHA bit is 0, the driving of valid data to the MOSI and MISO signals commences at an SSL signal assertion timing. The first RSPCK signal change timing that occurs after the SSL signal assertion becomes the first transfer data fetching timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSI and MISO signals is always 1/2 RSPCK cycle after the transfer data fetch timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.

t1 denotes a period from an SSL signal assertion to RSPCK oscillation (RSPCK delay). t2 denotes a period from the cessation of RSPCK oscillation to an SSL signal negation (SSL negation delay). t3 denotes a period in which SSL signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the system. For a description of t1, t2, and t3 when this module is in master mode, see section 16.4.3 (1), Master/Slave (with This LSI Acting as Master).

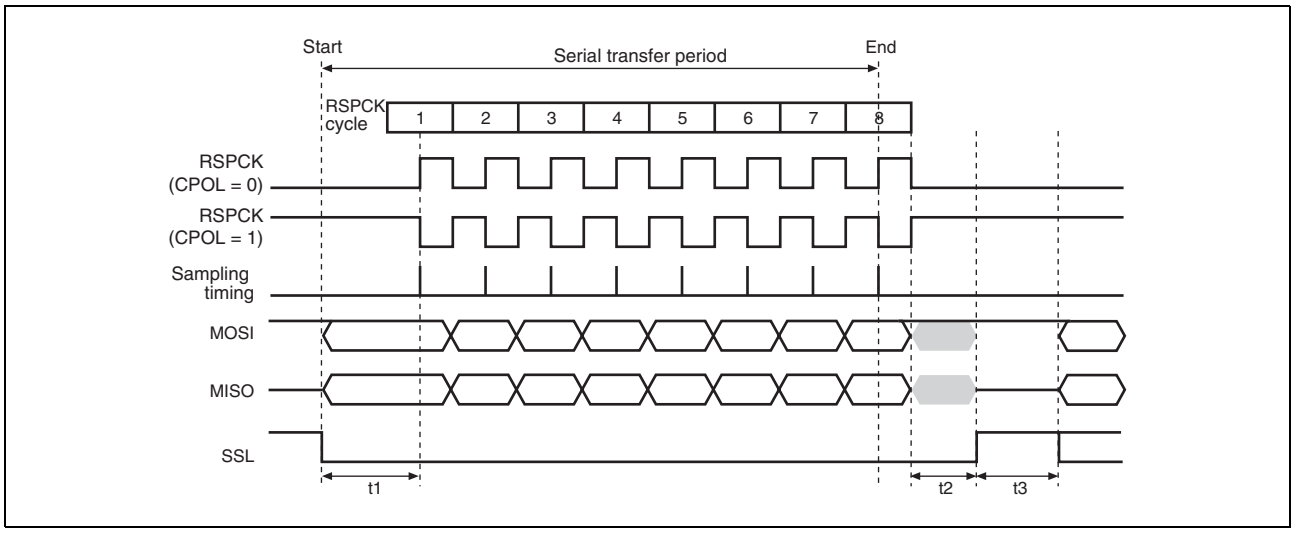

Figure 16.6 Transfer Format (CPHA = 0)

(2) CPHA = 1

Figure 16.7 shows a sample transfer format for the serial transfer of 8-bit data when the CPHA bit in the command register (SPCMD) is 1. In Figure 16.7, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which this module fetches serial transfer data into the shift register. The input/output directions of the signals depend on the modes (master or slave). For details, see section 16.4.2, Pin Control.
When the CPHA bit is 1, the driving of invalid data to the MOSI and MISO signals commences at an SSL signal assertion timing. The driving of valid data to the MOSI and MISO signals commences at the first RSPCK signal change timing that occurs after the SSL signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is always 1/2 RSPCK cycle after the data update timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.
t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when this module is in master mode, see section 16.4.3 (1), Master/Slave (with This LSI Acting as Master).

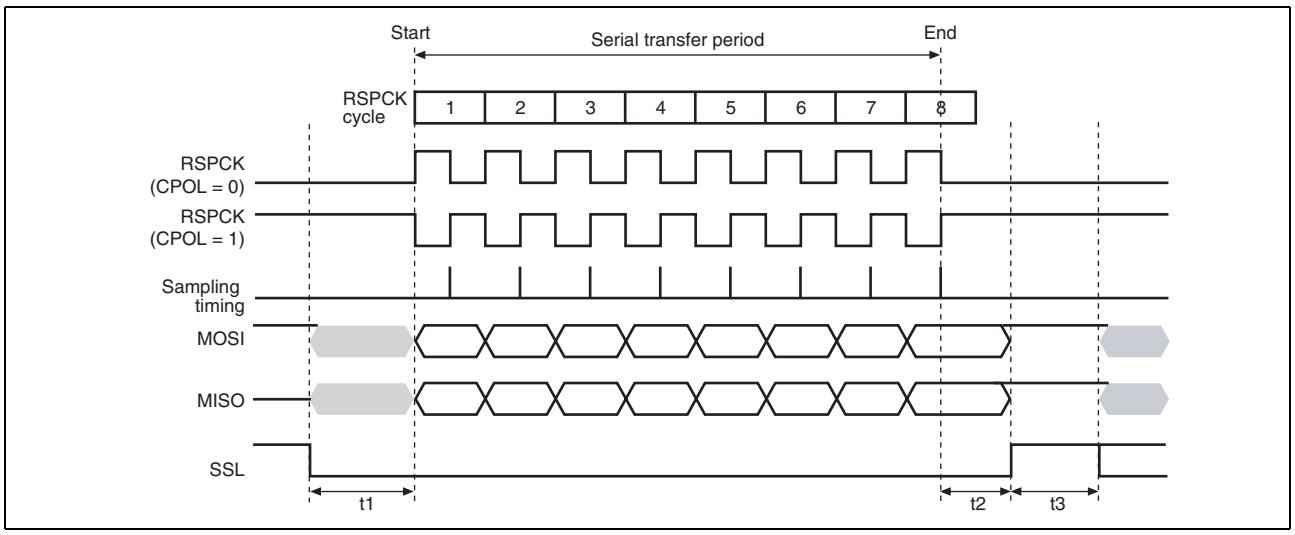

Figure 16.7 Transfer Format (CPHA = 1)

16.4.5 Data Format

The data format depends on the settings in the command register (SPCMD). Irrespective of MSB/LSB first, this module treats the range from the LSB of the data register (SPDR) to the assigned data length as transfer data.

(1) MSB First Transfer (32-Bit Data)

Figure 16.8 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 32-bit data length MSB-first data transfer.

The CPU or direct memory access controller writes T31 to T00 to the transmit buffer of SPDR. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R31 to R00 is stored in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after the receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R31 to R00 is shifted out from the shift register.

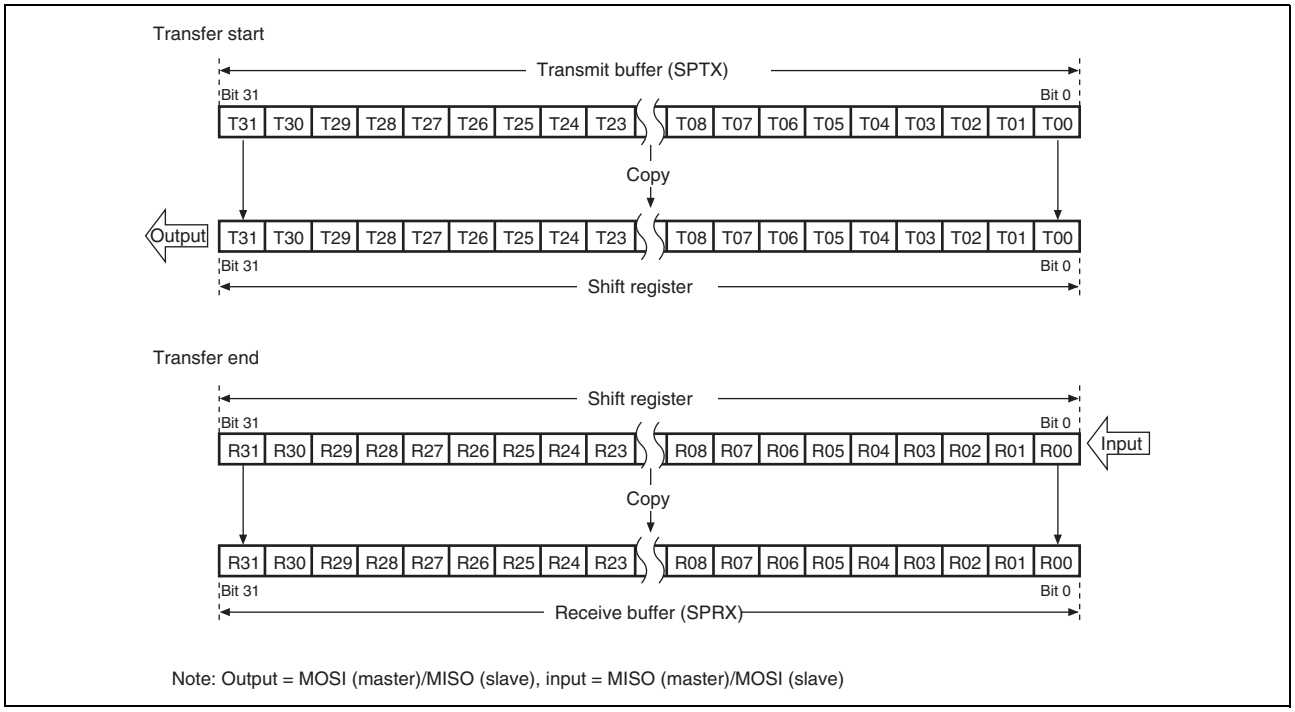

Figure 16.8 MSB First Transfer (32-Bit Data)

(2) MSB First Transfer (16-Bit Data)

Figure 16.9 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 16-bit data length MSB-first data transfer.

The CPU or direct memory access controller writes T15 to T00 to the transmit buffer. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from bit 15 in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 16 bits has passed, received data R15 to R00 is stored in bits 15 to 0 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 31 to 16 in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R15 to R00 is shifted out from the shift register.

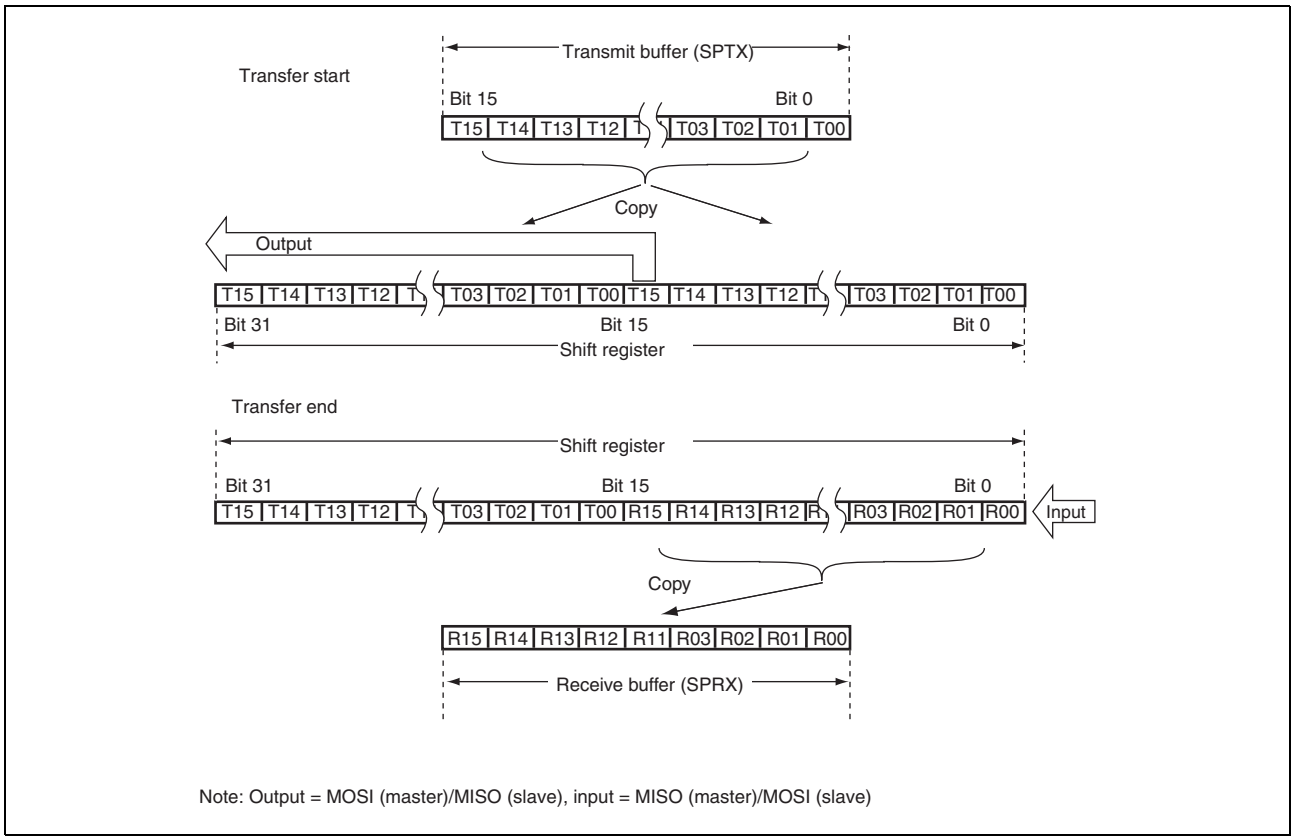

Figure 16.9 MSB First Transfer (16-Bit Data)

(3) MSB First Transfer (8-Bit Data)

Figure 16.10 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs an 8-bit data length MSB-first data transfer.

The CPU or direct memory access controller writes T07 to T00 to the transmit buffer. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from bit 7 in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 8 bits has passed, received data R07 to R00 is stored in bits 7 to 0 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 31 to 8 in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary area in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R07 to R00 is shifted out from the shift register.

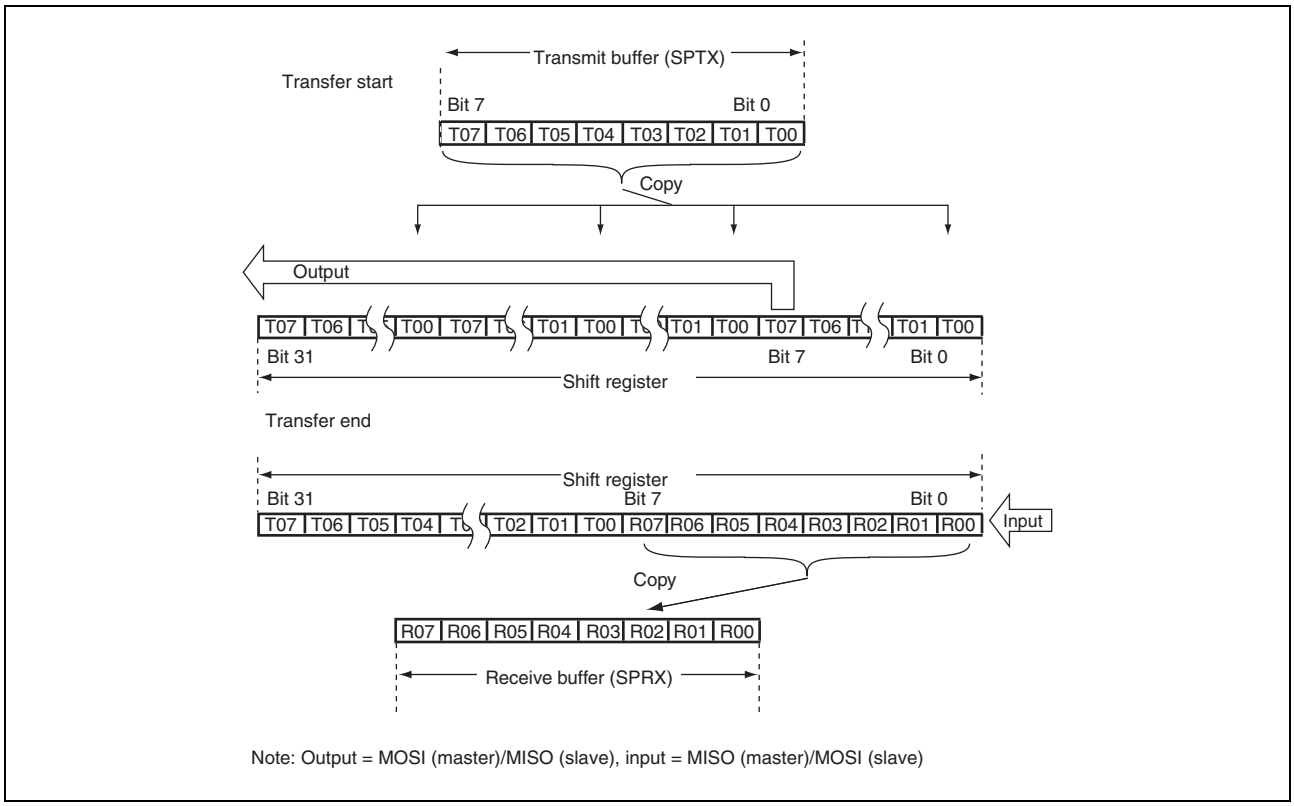

Figure 16.10 MSB First Transfer (8-Bit Data)

(4) LSB First Transfer (32-Bit Data)

Figure 16.11 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 32-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T31 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R00 to R31 is stored in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of the SPDR, received data R00 to R31 is shifted out from the shift register.

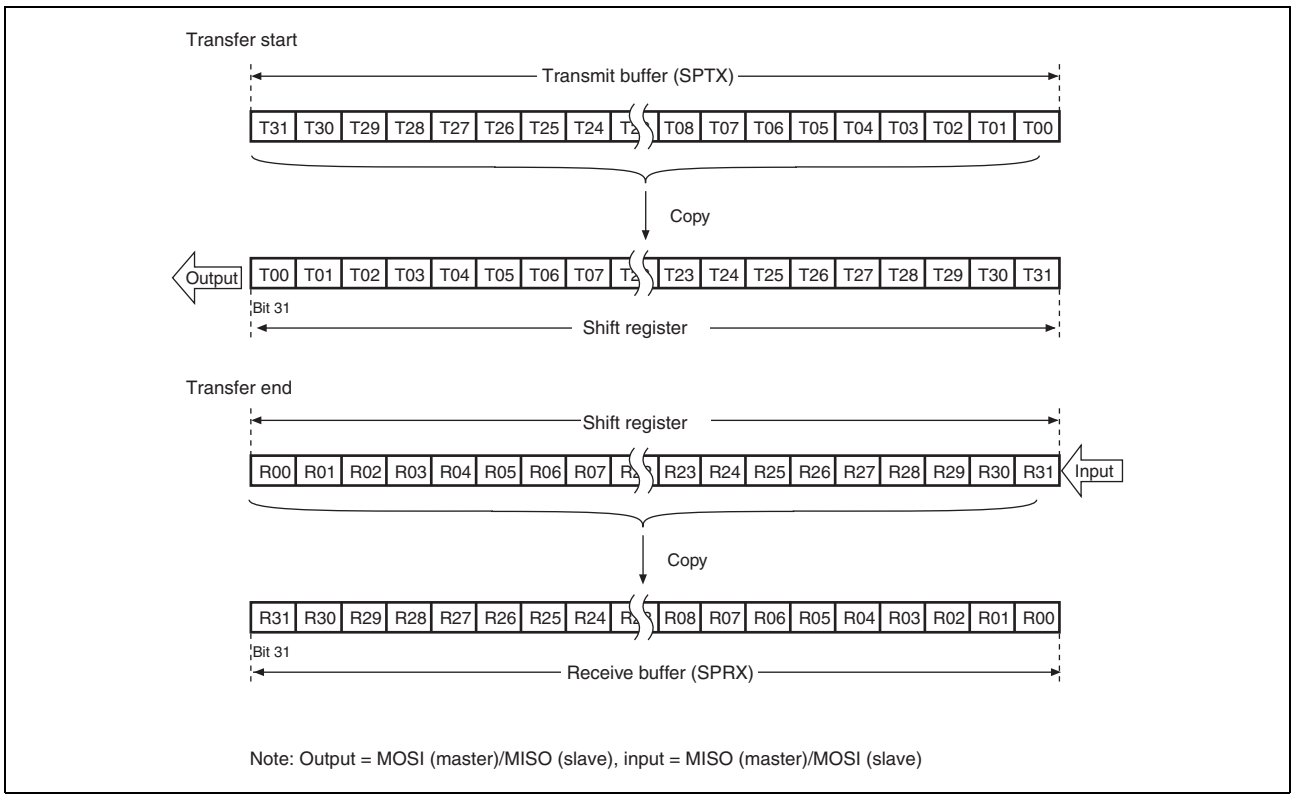

Figure 16.11 LSB First Transfer (32-Bit Data)

(5) LSB First Transfer (16-Bit Data)

Figure 16.12 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 16-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T15 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from bit 16 in the shift register. When the RSPCK cycle required for the serial transfer of 16 bits has passed, received data R00 to R15 is stored in bits 31 to 16 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 15 to 0 in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register.

If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of SPDR, received data R00 to R15 is shifted out from the shift register.

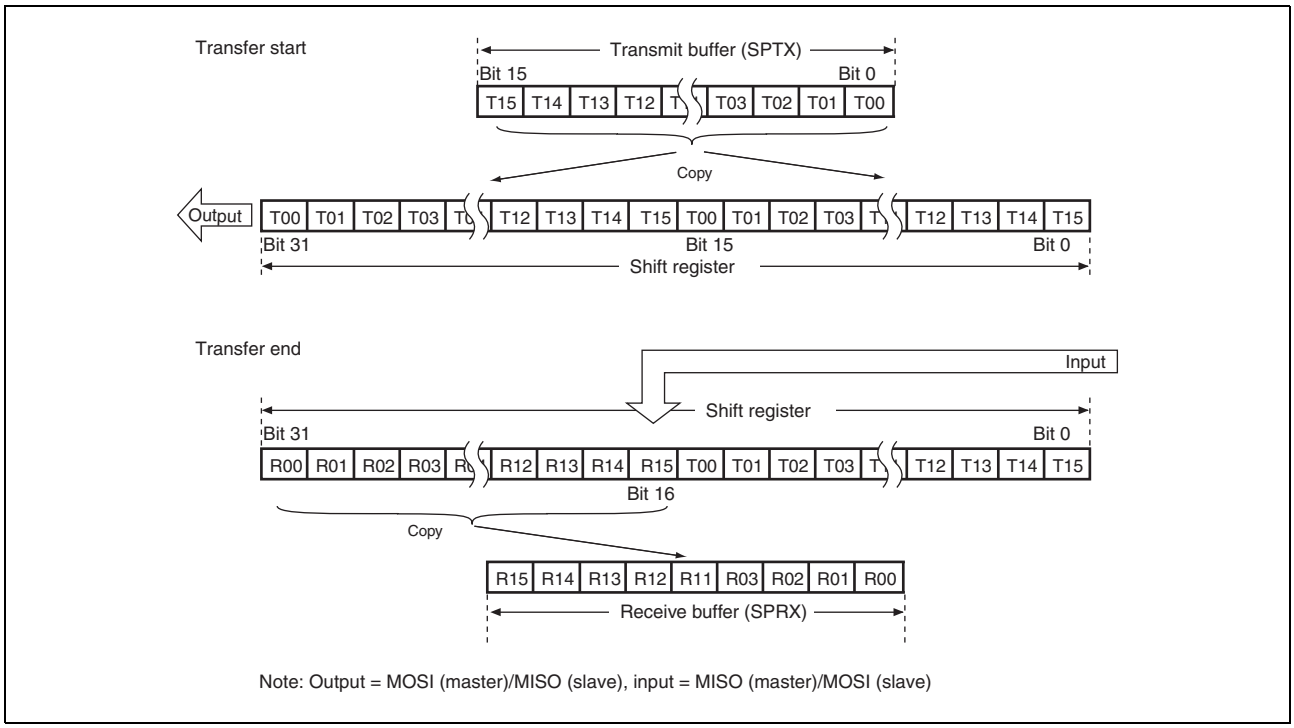

Figure 16.12 LSB First Transfer (16-Bit Data)

(6) LSB First Transfer (8-Bit Data)

Figure 16.13 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs an 8-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T07 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from bit 24 in the shift register. When the RSPCK cycle required for the serial transfer of 8 bits has passed, received data R00 to R07 is stored in bits 31 to 24 of the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 23 to 0 in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register. If the receive buffer does not have a space for the receive data length after the receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of SPDR, received data R00 to R07 is shifted out from the shift register.

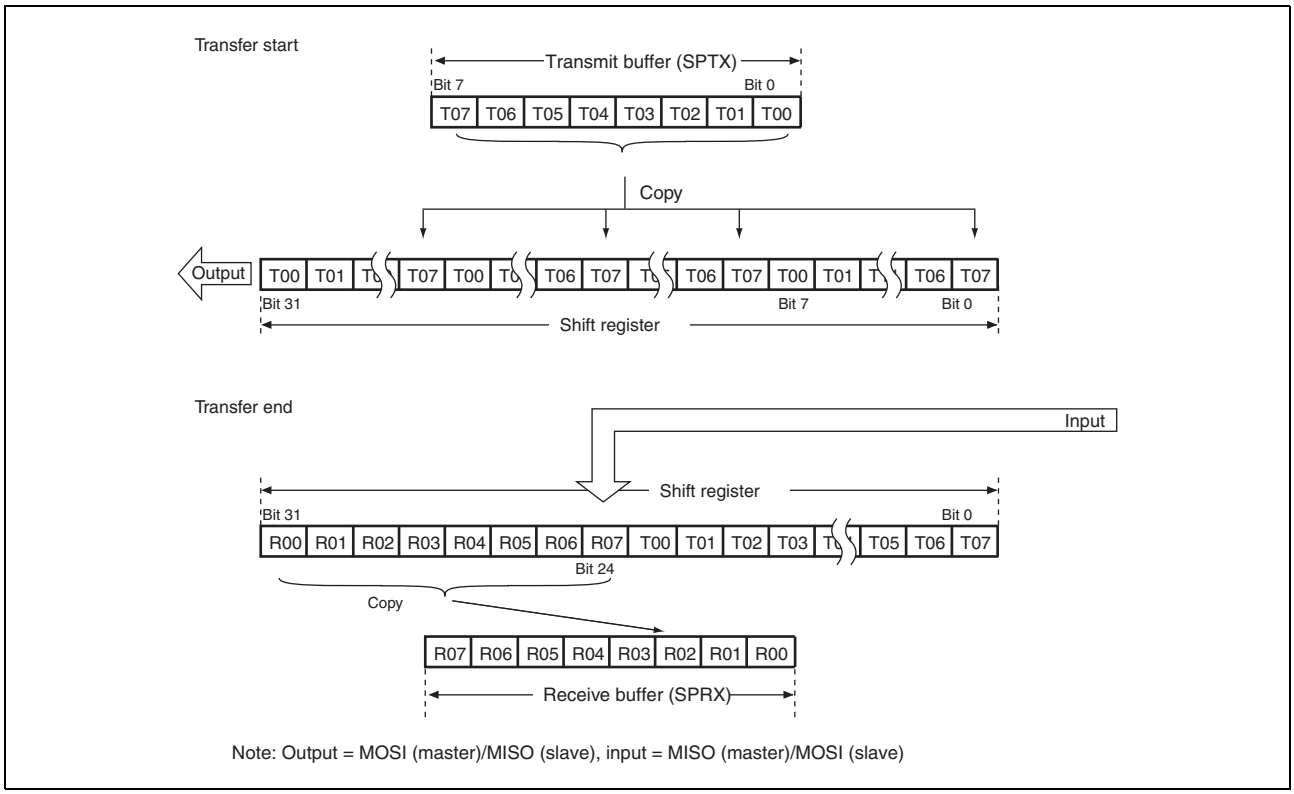

Figure 16.13 LSB First Transfer (8-Bit Data)

16.4.6 Error Detection

In the normal serial transfer, the data written to the transmit buffer of the data register (SPDR) is serially transmitted, and the serially received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit buffer/receive buffer or the status at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.
If a non-normal transfer operation occurs, this module detects the event as an overrun error or a mode fault error. Table 16.7 shows the relationship between non-normal transfer operations and the error detection function.

Table 16.7 Relationship between Non-Normal Transfer Operations and Error Detection Function

	Occurrence Condition	Operation	Error Detection
A	SPDR is written when the transmit buffer is full.	Missing write data.	None
B	Serial transfer is started in slave mode when transmit data is still not loaded on the shift register.	Data received in previous serial transfer is serially transmitted.	None
C	SPDR is read when the receive buffer is empty.	The output data is undefined.	None
D	Serial transfer terminates when the receive buffer is full.	Missing serial receive data.	Overrun error (only in slave mode)
E	The SSL input signal is negated during serial transfer in slave mode.	Serial transfer suspended. Missing send/receive data. Operation disabled.	Mode fault error

On operation A shown in Table 16.7, this module does not detect an error. Whether SPDR can be written to or not can be checked using the T[3:0] bits in the buffer data count setting register (SPBFDR).
Likewise, this module does not detect an error on operation B. In a serial transfer that was started before the shift register was updated, this module sends the data that was received in the previous serial transfer, and does not treat the operation indicated in B as an error. Note that the received data from the previous serial transfer is retained in the receive buffer of SPDR, thus it can be correctly read.
Similarly, this module does not detect an error on operation C. To prevent extraneous data from being read, the number of receive data units stored in the receive buffer should be read from the R[5:0] bits in the buffer data count setting register (SPBFDR).
An overrun error shown in D is described in section 16.4.6 (1), Overrun Error. A mode fault error shown in E is described in section 16.4.6 (2), Mode Fault Error.

(1) Overrun Error

If serial transfer ends when the receive buffer of the data register (SPDR) is full, this module detects an overrun error, and sets the OVRF bit in SPSR to 1. When the OVRF bit is 1, this module does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To reset the OVRF bit in SPSR to 0, either perform a power-on reset, or write a 0 to the OVRF bit after SPSR has been read with the OVRF bit set to 1.

Figure 16.14 shows an example of operation of the SPRF and OVRF bits in SPSR. The SPSR and SPDR accesses shown in Figure 16.14 indicate the condition of accesses to SPSR and SPDR, respectively, where I denotes an idle cycle, W a write cycle, and R a read cycle. In the example of Figure 16.14, this module performs an 8-bit serial transfer in which the CPHA bit in the command register (SPCMD) is 1, and CPOL is 0. The numbers given under the RSPCK waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

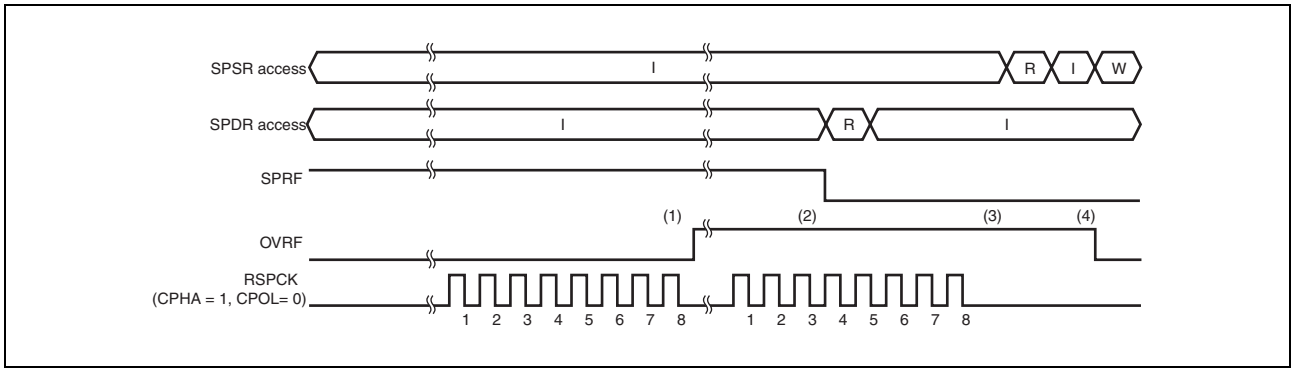

Figure 16.14 SPRF and OVRF Bit Operation Example

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

1. If a serial transfer terminates when the receive buffer does not have a space for the receive data length, this module detects an overrun error, and sets the OVRF bit to 1. This module does not copy the data in the shift register to the receive buffer.
2. The OVFR bit is not cleared even when SPDR is read and thus the number of data bytes in the receive buffer becomes less than the number of the receive buffer data triggering number specified by the RXTRG bits.
3. If the serial transfer terminates in an overrun error state, this module determines that the shift register is empty; in this manner, data transfer is enabled from the transmit buffer to the shift register.
4. If 0 is written to the OVRF bit after SPSR is read with OVRF = 1, this module clears the OVRF bit.

The occurrence of an overrun can be checked either by reading SPSR or by using an error interrupt and reading SPSR. When using an error interrupt, set the SPEIE bit in the control register (SPCR) to 1. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading SPSR immediately after SPDR is read.

The OVRF bit is cleared to 0 under the following conditions:

- After SPSR is read in a condition in which the OVRF bit is set to 1, 0 is written to the OVRF bit.
- Power-on reset

Note: • When the receive buffer has area enough to store receive data with an overrun error, this module receives receive data.

(2) Mode Fault Error

When the MSTR bit is 0, this module operates in slave mode. This module detects a mode fault error if the SSL input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched) when the MODFEN bit is 1 in slave mode.
Upon detecting a mode fault error, this module stops driving of the output signals and clears the SPE bit in SPCR to 0. When the SPE bit is cleared to 0, the function of this module is disabled and this module stops driving external signals. For details of disabling the function of this module by clearing the SPE bit to 0, see section 16.4.7, Initialization.
The occurrence of a mode fault error can be checked either by reading SPSR or by using an error interrupt and reading SPSR. When using an error interrupt, set the SPEIE bit in the control register (SPCR) to 1. To detect a mode fault error without using an error interrupt, it is necessary to poll SPSR.
When the MODF bit is 1, writing 1 to the SPE bit is ignored. To enable the function of this module after the detection of a mode fault error, the MODF bit must be set to 0. The MODF bit is cleared to 0 under the following conditions:

- After SPSR is read in a condition where the MODF bit has turned 1, 0 is written to the MODF bit.
- Power-on reset

16.4.7 Initialization

If 0 is written to the SPE bit in the control register (SPCR) or this module clears the SPE bit to 0 because of the detection of a mode fault error, this module disables the module function, and initializes a part of the module function. When a power-on reset is generated, this module initializes all of the module function. An explanation follows of initialization by the clearing of the SPE bit.

(1) Initialization by Clearing SPE Bit

When the SPE bit in SPCR is cleared, this module performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state
- Initializing the TEND bit in SPSR

Initialization by the clearing of the SPE bit does not initialize the control bits of this module. For this reason, this module can be started in the same transfer mode as prior to the initialization if the SPE bit is re-set to 1.

16.4.8 SPI Operation

(1) Multi-Master Mode Operation

This section explains the operation in multi-master mode.

(a) Starting Serial Transfer

A serial transfer is started when transmit data is copied from the transmit buffer to the shift register, the shift register becomes full, and the receive buffer has a space for the receive data length. If transmit data has already been written to the shift register, data is not copied from the transmit buffer to the shift register.
For details of the transfer format, see section 16.4.4, Transfer Format.

(b) Terminating Serial Transfer

Irrespective of the CPHA bit in the command register (SPCMD), this module terminates the serial transfer after transmitting an RSPCK edge corresponding to the final sampling timing. After the serial transfer is completed, receive data is copied from the shift register to the receive buffer. If the receive buffer does not have a space for the receive data length after receive data is copied from the shift register to the receive buffer, another serial transfer will not be performed. In order to perform another serial transfer, data for the receive data length should be read from the receive buffer to secure the space for the receive data.
It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the data length depends on the settings in bits SPB3 to SPB0 in SPCMD. For details on the transfer format, see section 16.4.4, Transfer Format.

(c) Sequence Control

The transfer format that is employed in master mode is determined by the sequence control register (SPSCR), command registers 0 to 3 (SPCMD0 to SPCMD3), the bit rate register (SPBR), the clock delay register (SPCKD), the slave select negation delay register (SSLND), and the next-access delay register (SPND).
SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by this module in master mode. The following items are set in command registers SPCMD0 to SPCMD3: SSL output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, a clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.
According to the sequence length that is assigned to SPSCR, this module makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3. This module contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading bits SPCP1 and SPCP0 in the sequence status register (SPSSR). When the SPE bit in the control register (SPCR) is set to 1 and the function of this module is enabled, this module loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. This module increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, this module sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

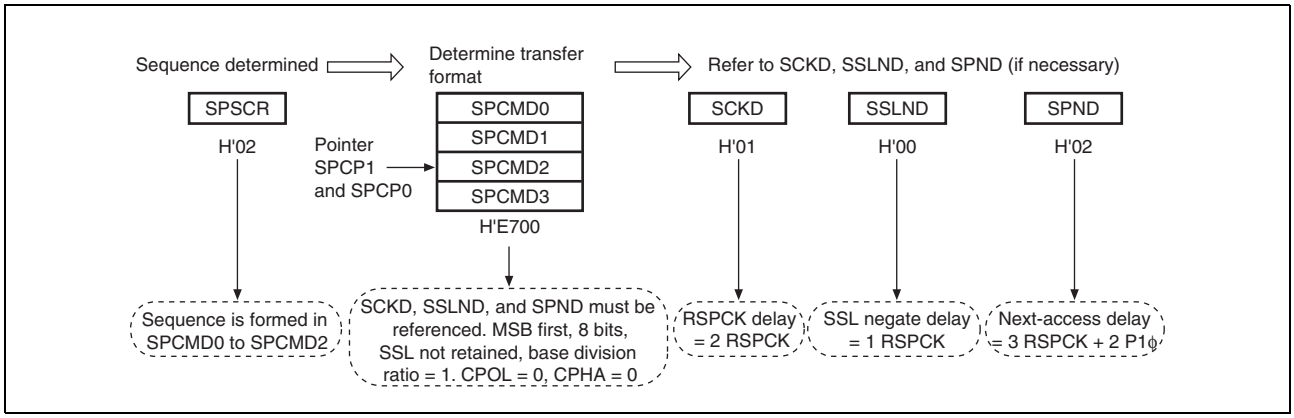

Figure 16.15 Determination Procedure of Serial Transfer Mode in Master Mode

(d) Burst Transfer

If the SSLKP bit in the command register (SPCMD) that this module references during the current serial transfer is 1, this module keeps the SSL signal level during the serial transfer until the beginning of the SSL signal assertion for the next serial transfer. If the SSL signal level for the next serial transfer is the same as the SSL signal level for the current serial transfer, this module can execute continuous serial transfers while keeping the SSL signal assertion status (burst transfer).

Figure 16.16 shows an example of an SSL signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 settings. The text below explains operations (1) to (7) as depicted in Figure 16.16. It should be noted that the polarity of the SSL output signal depends on the settings in the slave select polarity register (SSLP).

1. Based on SPCMD0, this module asserts the SSL signal and inserts RSPCK delays.
2. Serial transfers are executed according to SPCMD0.
3. SSL negation delays are inserted.
4. Because the SSLKP bit in SPCMD0 is 1, this module keeps the SSL signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0. If the shift register is empty after the passage of a minimum period, this period is sustained until such time as the transmit data is stored in the shift register for another transfer.
5. Based on SPCMD1, this module asserts the SSL signal and inserts RSPCK delays.
6. Serial transfers are executed according to SPCMD1.
7. Because the SSLKP bit in SPCMD1 is 0, this module negates the SSL signal. In addition, a next-access delay is inserted according to SPCMD1.

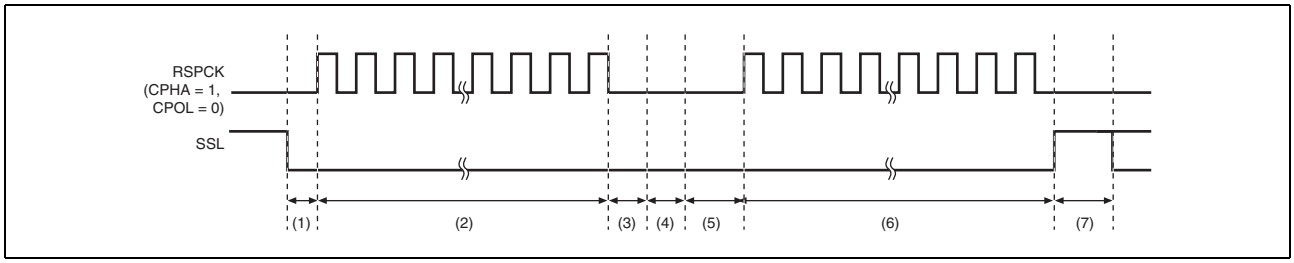

Figure 16.16 Example of Burst Transfer Operation using SSLKP Bit

If the SSL signal settings in the SPCMD in which 1 is assigned to the SSLKP bit are different from the SSL signal output settings in the SPCMD to be used in the next transfer, this module switches the SSL signal status to SSL signal assertion ((5) in Figure 16.16) corresponding to the command for the next transfer. Notice that if such an SSL signal switching occurs, the slaves that drive the MISO signal compete, and the possibility arises of the collision of signal levels.

This module in master mode references within the module the SSL signal operation for the case where the SSLKP bit is

not used. Even when the CPHA bit in SPCMD is 0, this module can accurately start serial transfers by asserting the SSL signal for the next transfer. For this reason, burst transfers in master mode can be executed irrespective of CPHA bit settings (see section 16.4.8 (2), Slave Mode Operation).

(e) RSPCK Delay (t1)

The RSPCK delay value in master mode depends on SCKDEN bit settings in the command register (SPCMD) and on clock delay register (SPCKD) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SCKDEN bit in the selected SPCMD and SPCKD, as shown in Table 16.8. For a definition of RSPCK delay, see section 16.4.4, Transfer Format.

Table 16.8 Relationship among SCKDEN and SPCKD Settings and RSPCK Delay Values

SCKDEN	SPCKD	RSPCK Delay Value
0	000 to 111	1 RSPCK
1	000	1 RSPCK
	001	2 RSPCK
	010	3 RSPCK
	011	4 RSPCK
	100	5 RSPCK
	101	6 RSPCK
	110	7 RSPCK
	111	8 RSPCK

(f) SSL Negation Delay (t2)

The SSL negation delay value in master mode depends on SLNDEN bit settings in the command register (SPCMD) and on SSL negation delay register (SSLND) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SLNDEN bit in the selected SPCMD and SSLND, as shown in Table 16.9. For a definition of SSL negation delay, see section 16.4.4, Transfer Format.

Table 16.9 Relationship among SLNDEN and SSLND Settings and SSL Negation Delay Values

SLNDEN	SSLND	SSL Negation Delay Value
0	000 to 111	1 RSPCK
1	000	1 RSPCK
	001	2 RSPCK
	010	3 RSPCK
	011	4 RSPCK
	100	5 RSPCK
	101	6 RSPCK
	110	7 RSPCK
	111	8 RSPCK

(g) Next-Access Delay (t3)

The next-access delay value in master mode depends on SPNDEN bit settings in the command register (SPCMD) and on next-access delay register (SPND) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPNDEN bit in the selected SPCMD and SPND, as shown in Table 16.10. For a definition of next-access delay, see section 16.4.4, Transfer Format.

Table 16.10 Relationship among SPNDEN and SPND Settings and Next-Access Delay Values

SPNDEN	SPND	Next-Access Delay Value
0	000 to 111	1 RSPCK + 2 P1ϕ
1	000	1 RSPCK + 2 P1ϕ
	001	2 RSPCK + 2 P1ϕ
	010	3 RSPCK + 2 P1ϕ
	011	4 RSPCK + 2 P1ϕ
	100	5 RSPCK + 2 P1ϕ
	101	6 RSPCK + 2 P1ϕ
	110	7 RSPCK + 2 P1ϕ
	111	8 RSPCK + 2 P1ϕ

(h) Initialization Flowchart

Figure 16.17 is a flowchart illustrating an example of initialization in SPI operation when this module is used in master mode. For a description of how to set up the interrupt controller, direct memory access controller, and input/output ports, see the descriptions given in the individual blocks.

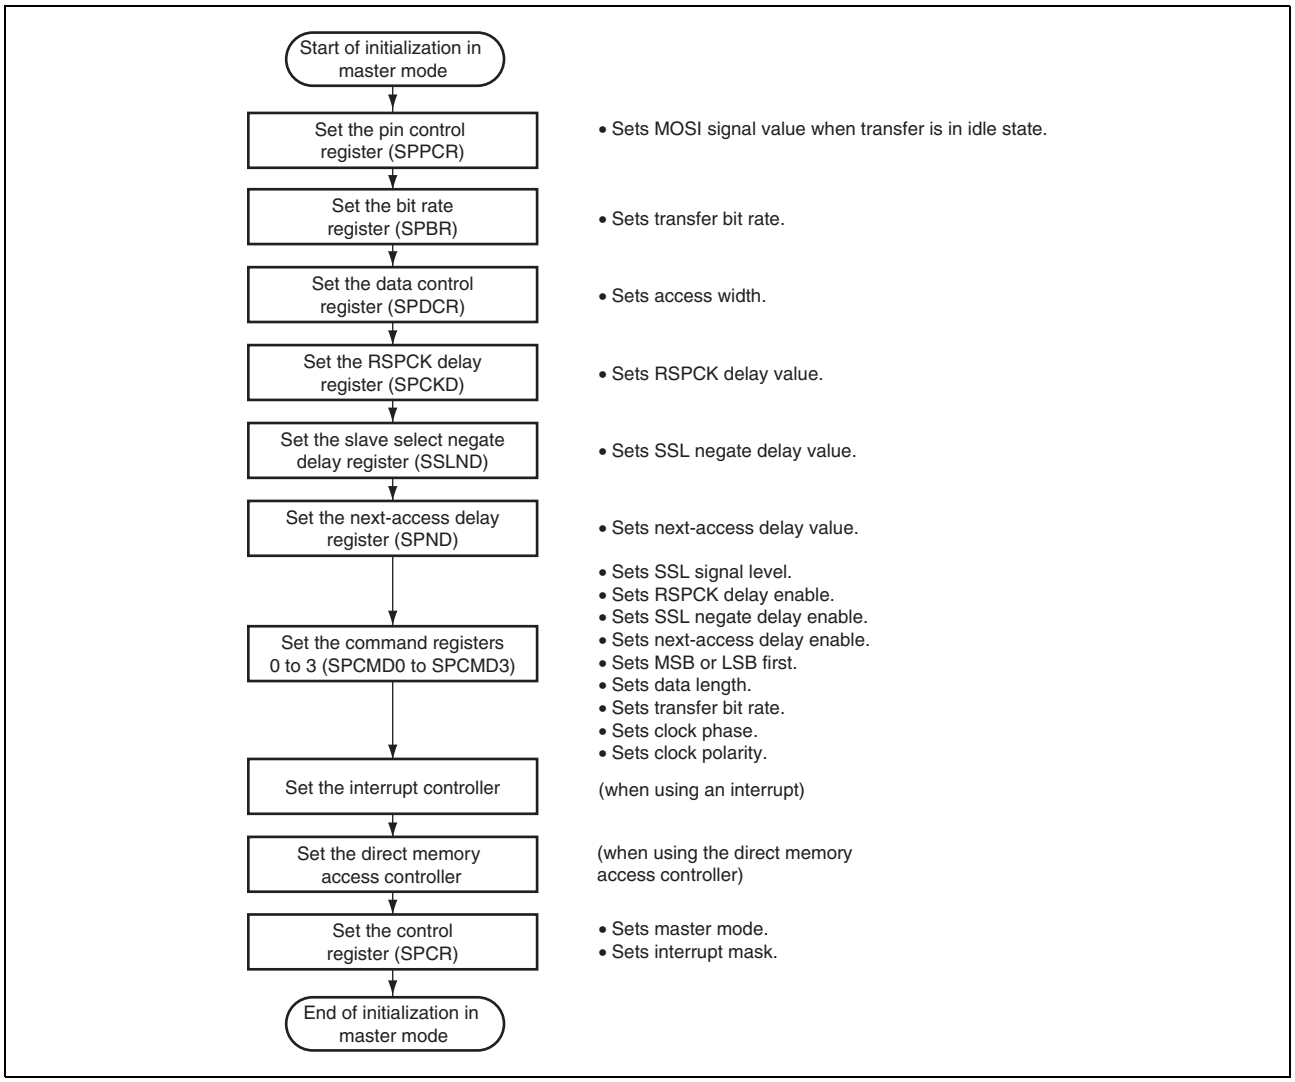

Figure 16.17 Example of Initialization Flowchart in Master Mode

(i) Transfer Operation Flowchart

Figure 16.18 is a flowchart illustrating a transfer in SPI operation when this module is used in master mode.

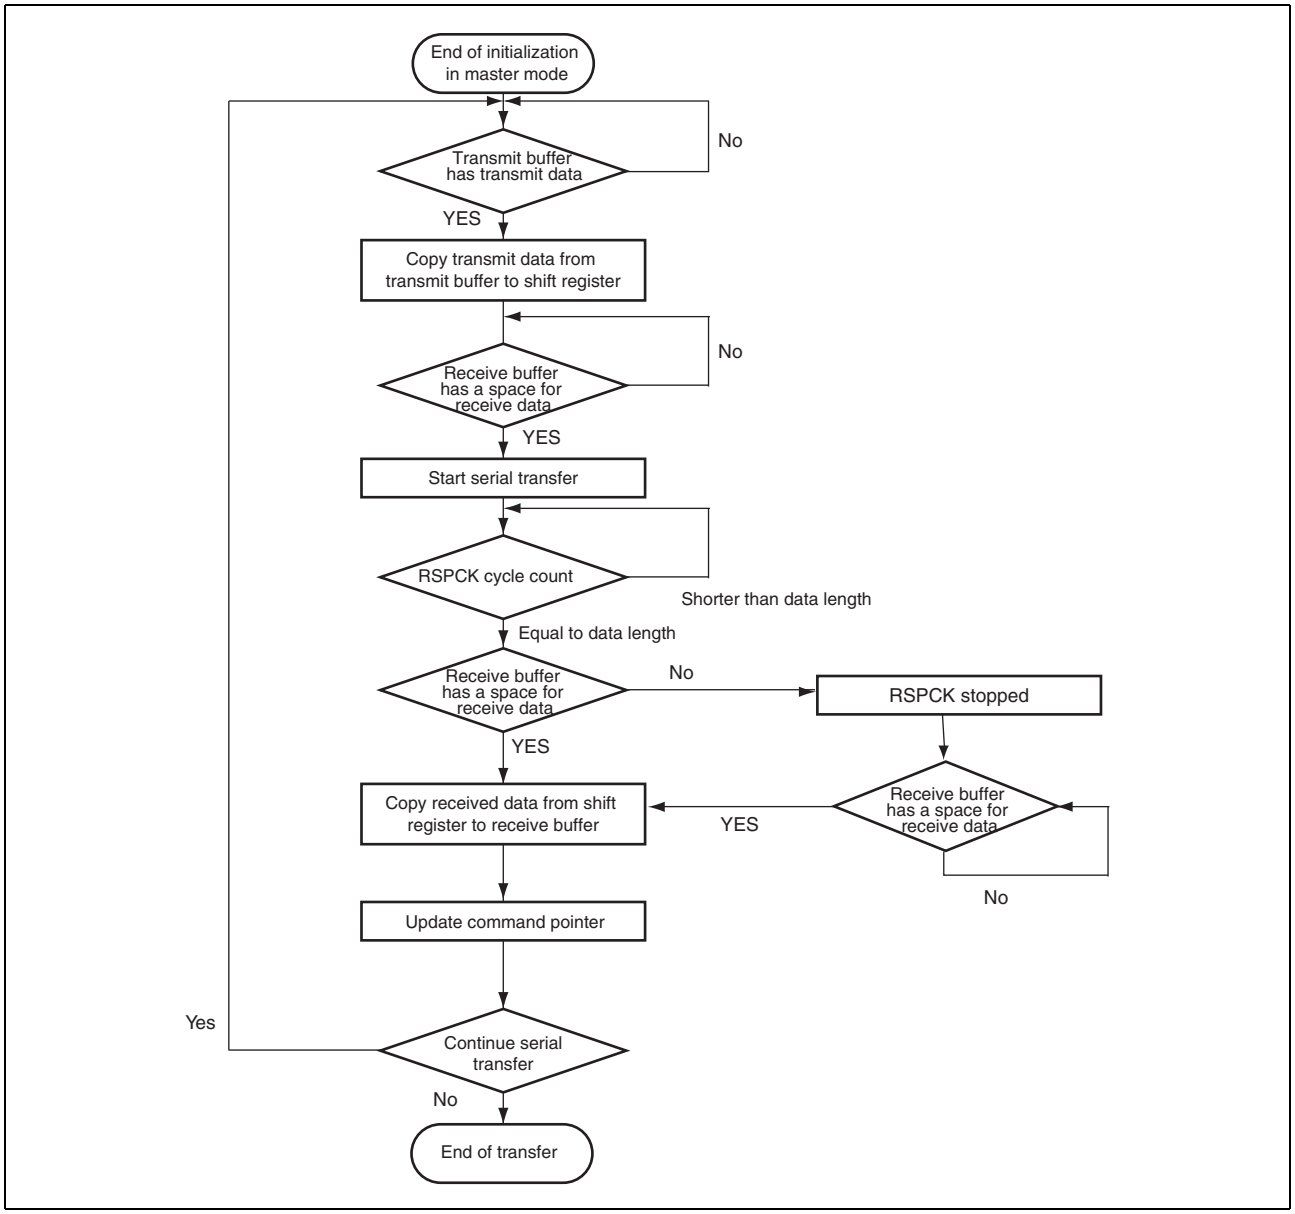

Figure 16.18 Transfer Operation Flowchart in Master Mode

(2) Slave Mode Operation

(a) Starting Serial Transfer

If this module detects an SSL input signal assertion when the CPHA bit in the command register 0 (SPCMD0) is 0, this module is required to start driving valid data to the MISO output signal. For this reason, when the CPHA bit is 0, the asserting of the SSL input signal triggers the start of a serial transfer.
If this module detects the first RSPCK edge in an SSL signal asserted condition when the CPHA bit is 1, this module is required to start driving valid data to the MISO output signal. For this reason, when the CPHA bit is 1, the first RSPCK edge in an SSL signal asserted condition triggers the start of a serial transfer.
When detecting the start of a serial transfer in a condition in which the shift register is empty, this module changes the status of the shift register to "full", so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, this module leaves the status of the shift register intact, in the full state.
Irrespective of CPHA bit settings, this module starts driving MISO output signals at the SSL signal assertion timing. Whether the data output from this module is valid or invalid differs depending on CPHA bit settings.
For details on the transfer format, see section 16.4.4, Transfer Format. The polarity of the SSL input signal depends on the setting of the SSL0P bit in the slave select polarity register (SSLP).

(b) Terminating Serial Transfer

Irrespective of the CPHA bit in the command register 0 (SPCMD0), this module terminates the serial transfer after detecting an RSPCK edge corresponding to the final sampling timing. When the receive buffer has an enough space for receive data, this module copies received data from the shift register to the receive buffer of the data register (SPDR) upon termination of the serial transfer. Irrespective of the value of the SPRF bit, this module changes the status of the shift register to "empty" upon termination of the serial transfer. If this module detects an SSL input signal negation from the beginning of serial transfer to the end of serial transfer, a mode fault error occurs (see section 16.4.6, Error Detection).
The final sampling timing changes depending on the bit length of the transfer data. In slave mode, the data length depends on the settings in bits SPB3 to SPB0 bits in SPCMD0. The polarity of the SSL input signal depends on the setting in the SSL0P bit in the slave select polarity register (SSLP). For details on the transfer format, see section 16.4.4, Transfer Format.

(c) Notes on Slave Operations

If the CPHA bit in the command register 0(SPCMD0) is 0, this module starts serial transfers when it detects the assertion edge for an SSL input signal. In the type of configuration shown in Figure 16.4 as an example, if this module is used in single-slave mode, the SSL signal is always fixed at active state. Therefore, when the CPHA bit is set to 0, this module cannot correctly start a serial transfer. To correctly execute send/receive operation in a configuration in which the SSL input signal is fixed at active state, the CPHA bit should be set to 1. When it is necessary to set the CPHA bit to 0, the SSL input signal should not be fixed.

(d) Burst Transfer

If the CPHA bit in the command register 0 (SPCMD0) is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSL input signal. If the CPHA bit is 1, the period from the first RSPCK edge to the sampling timing for the reception of the final bit in an SSL signal active state corresponds to a serial transfer period. Even when the SSL input signal remains at the active level, this module can accommodate burst transfers because it can detect the start of access.
If the CPHA bit is 0, for the reason given in section 16.4.8 (2) (c), Notes on Slave Operations, second and subsequent serial transfers during the burst transfer cannot be executed correctly.

(e) Initialization Flowchart

Figure 16.19 is a flowchart illustrating an example of initialization in SPI operation when this module is used in slave mode. For a description of how to set up the interrupt controller, direct memory access controller, and input/output ports, see the descriptions given in the individual blocks.

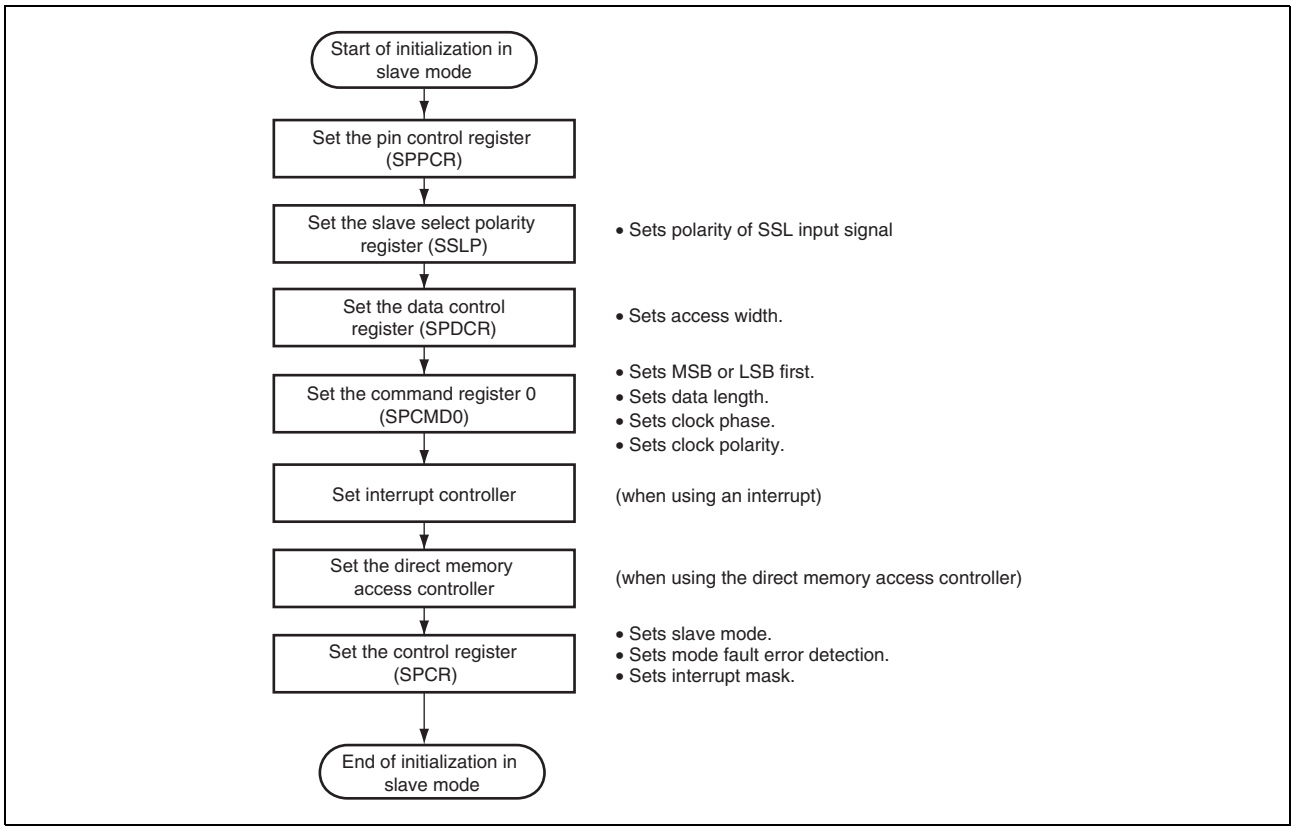

Figure 16.19 Example of Initialization Flowchart in Slave Mode

(f) Transfer Operation Flowchart (CPHA = 0)

Figure 16.20 is a flowchart illustrating a transfer in SPI operation when this module is used in slave mode with the CPHA bit in the command register 0 (SPCMD0) set to 0.

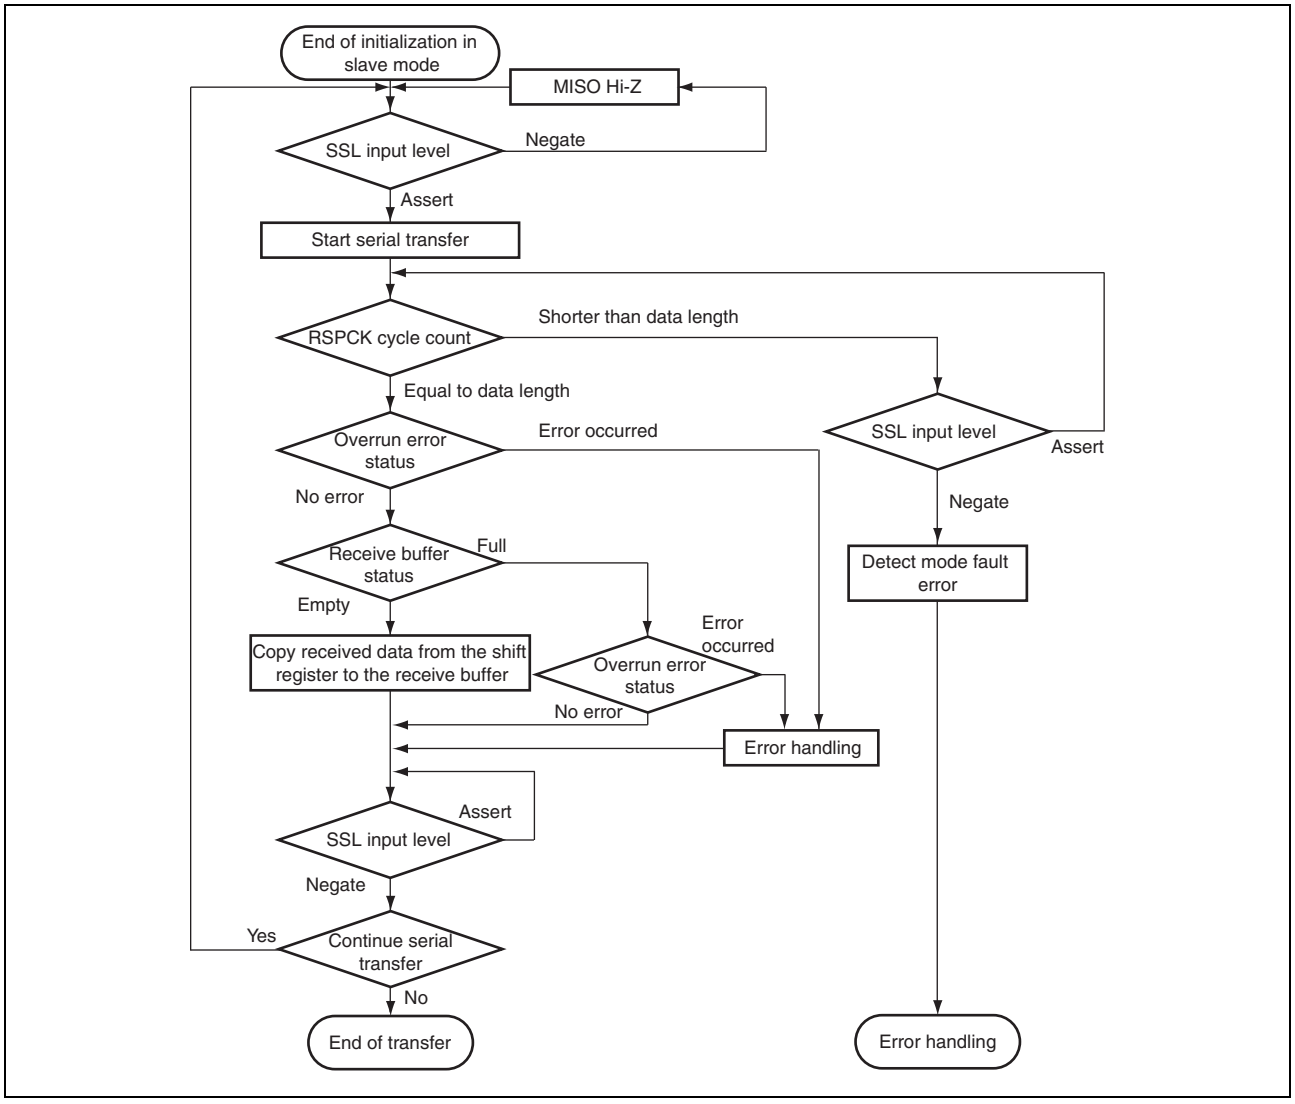

Figure 16.20 Transfer Operation Flowchart in Slave Mode (CPHA = 0)

(g) Transfer Operation Flowchart (CPHA = 1)

Figure 16.21 is a flowchart illustrating a transfer in SPI operation when this module is used in slave mode with the CPHA bit in the command register 0 (SPCMD0) and the MODFEN bit in the control register (SPCR) set to 1, respectively. The subsequent operation is not guaranteed when the serial transfer is started with the MODFEN bit set to 0 and the SSL input level is negated with the number of RSPCK cycles shorter than the data length.

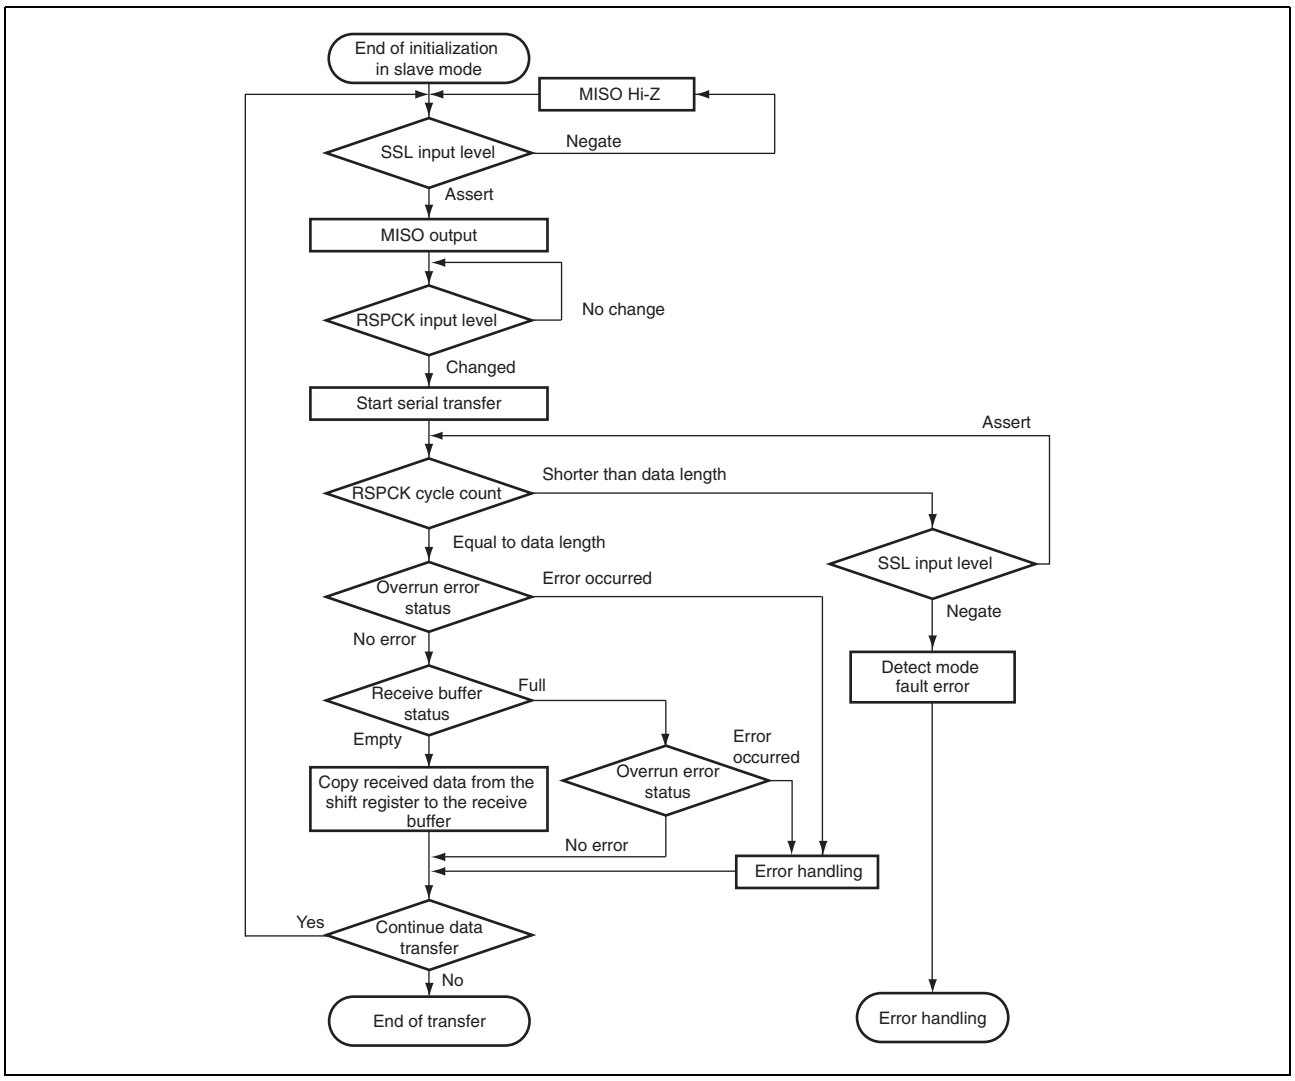

Figure 16.21 Transfer Operation Flowchart in Slave Mode (CPHA = 1)

16.4.9 Error Handling

Figure 16.22 and Figure 16.23 show the error handling. The following error handling is used to return from the error state after an error in master or slave mode.

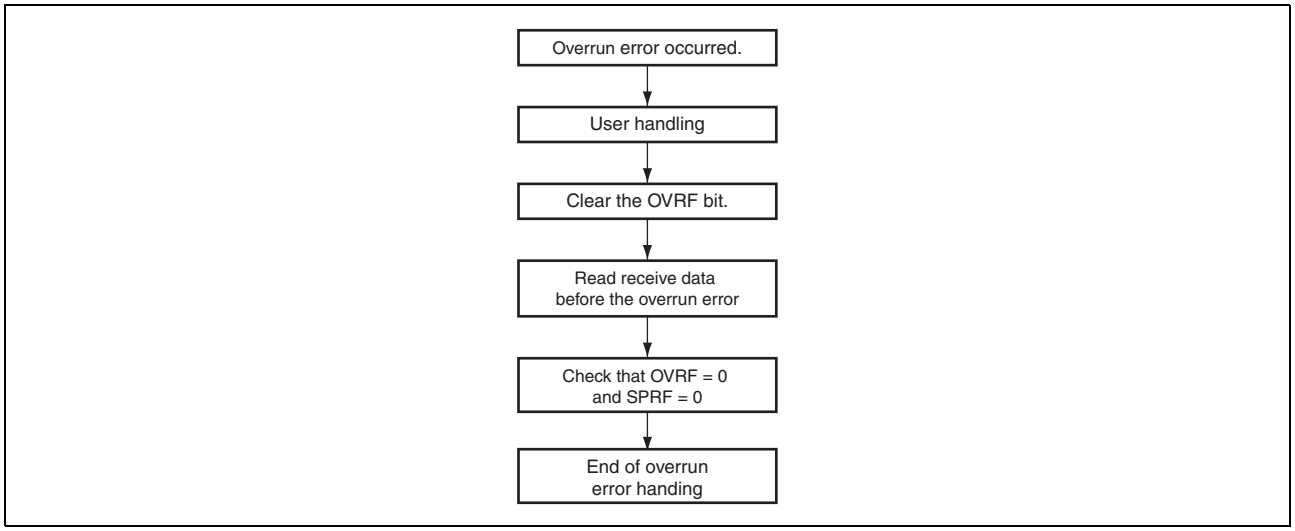

Figure 16.22 Error Handling (Overrun Error)

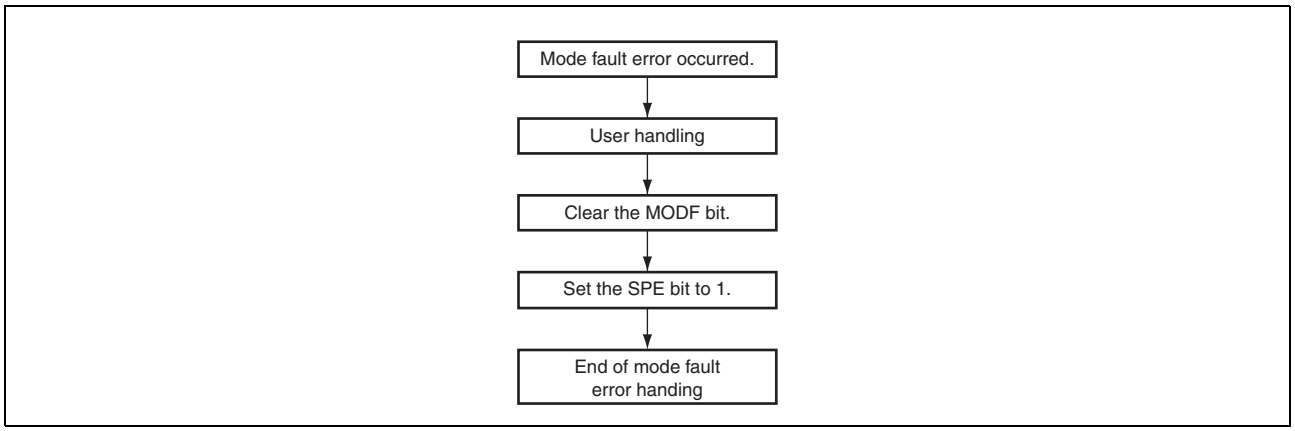

Figure 16.23 Error Handling (Mode Fault Error)

16.4.10 Loopback Mode

When 1 is written to the SPLP bit in the pin control register (SPPCR), this module shuts off the path between the MISO pin and the shift register, and between the MOSI pin and the shift register, and connects the input path and the output path (reversed) of the shift register. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data becomes the received data. Figure 16.24 shows the configuration of the shift register input/output paths for the case where this module in master mode is set in loopback mode.

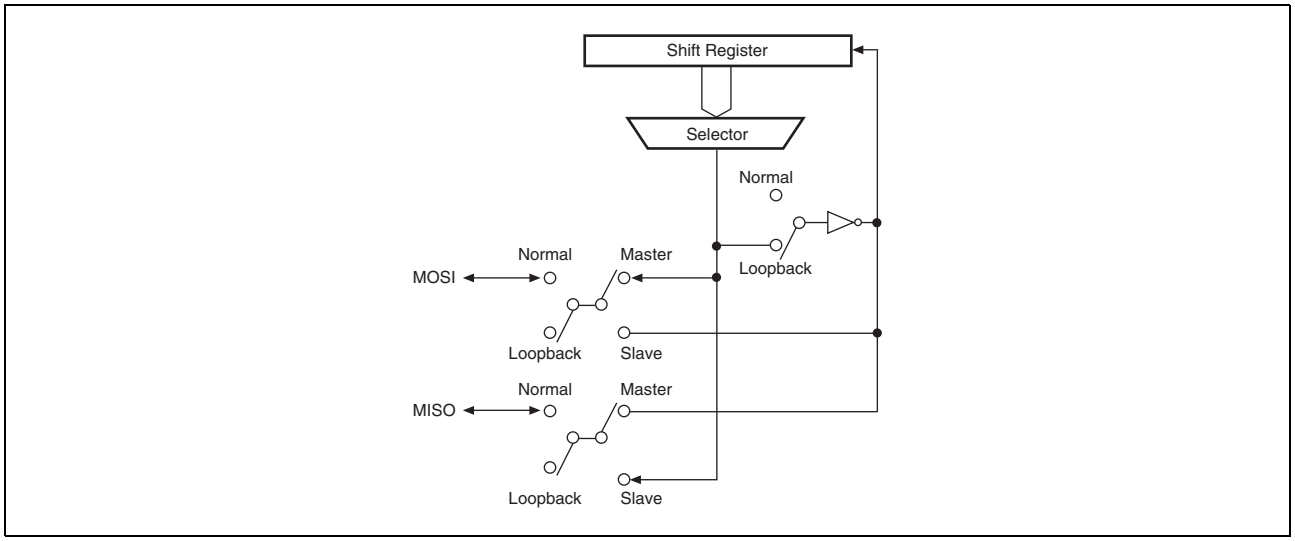

Figure 16.24 Configuration of Shift Register Input/Output Paths in Loopback Mode (Master Mode)

16.4.11 Interrupt Sources

This module has interrupt sources of receive buffer full, transmit buffer empty, mode fault, and overrun. In addition, the direct memory access controller can be activated by the receive buffer full or transmit buffer empty interrupt for data transfer.

Table 16.11 shows the interrupt sources.

When any of the interrupt conditions in Table 16.11 is met, an interrupt is generated. The interrupt sources should be cleared with data transfer by the CPU or direct memory access controller.

Table 16.11 Interrupt Sources

Name	Interrupt Source	Abbreviation	Interrupt Condition	Activation of Direct Memory Access Controller
SPRI	Receive buffer full	RXI	(SPRIE = 1) • (SPRF = 1)	Possible
SPTI	Transmit buffer empty	TXI	(SPTIE = 1) • (SPTEF = 1)	Possible
SPEI	Mode fault	MOI	(SPEIE = 1) • (MODF = 1)	—
	Overrun	OVI	(SPEIE = 1) • (OVRF = 1)	—

17. SPI Multi I/O Bus Controller

The SPI multi I/O bus controller outputs control signals to the serial flash memory connected to the SPI multi I/O bus space, thus enabling direct connection of the serial flash memory.
This LSI incorporates an independent SPI multi I/O bus controller channel.

17.1 Features

This module allows the connected serial flash memory to be accessed by directly reading the SPI multi I/O bus space, or using SPI operating mode to transmit and receive data.

- Serial Flash Memory Interface
  Up to two serial flash memories per channel can be connected.
  A data bus size of 1 bit, 2 bits, or 4 bits can be selected for one serial flash memory device.
  Serial flash memory for DDR transfer can be directly connected (RZ/A1LU only).
- External Address Space Read Mode
  A maximum of 8-Gbyte address space is supported (when two serial flash memories are connected)
  The SPBSSL pin can be automatically controlled through access address monitoring
  Efficient data reception due to built-in read cache (64-bit line × 16 entries)
- SPI Operating Mode
  Desired read/write access to serial flash memory possible
- Bit rate
  SPBCLK is generated by frequency division of Bϕ by internal baud rate generator
  SPBCLK frequency division ratio can be set from 2 to 4080
- SPBSSL Pin Control
  Delay from SPBSSL signal assertion to SPBCLK operation (clock delay) can be set
  Range: 1 to 8 SPBCLK cycles (set in SPBCLK-cycle units)
  Delay from SPBCLK stop to SPBSSL output negation (SPBSSL negation delay) can be set
  Range: 1.5 to 8.5 SPBCLK cycles (set in SPBCLK-cycle units)
  SPBSSL output assertion wait before next access (next access delay) can be set
  Range: 1 to 8 SPBCLK cycles (set in SPBCLK-cycle units)
  SPBSSL polarity can be changed

17.2 Block Diagram

Figure 17.1 shows a block diagram of this module for one channel.

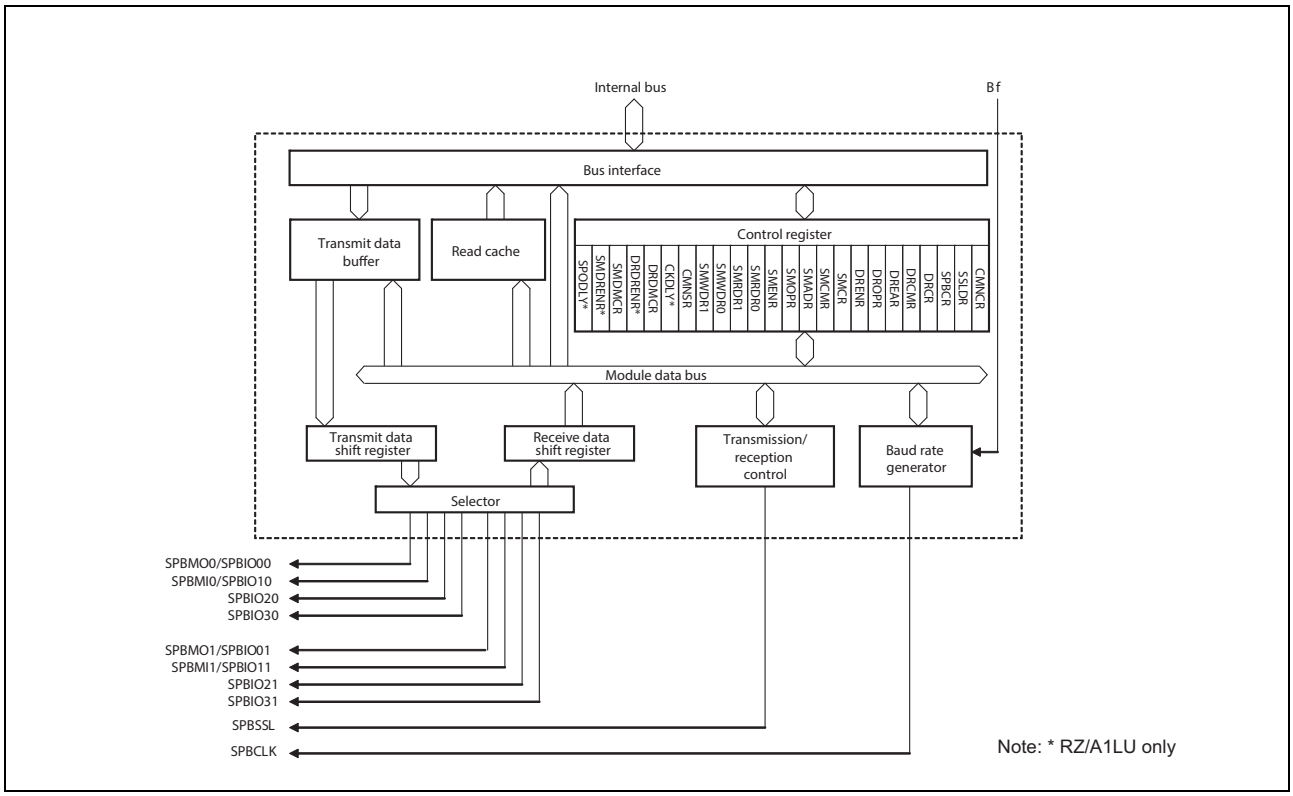

Figure 17.1 Block Diagram

17.3 Input/Output Pins

Table 17.1 shows the pin configuration for one channel.

Table 17.1 Pin Configuration

Port	Pin Name	Symbol	I/O	Function
Common	Clock pin	SPBCLK_n	Output	Clock output
	Slave select pin	SPBSSL_n	Output	Slave selection
0	Data 0 pin	SPBMO0_n/ SPBIO00_n	I/O	Port 0 master transmit data/data 0
	Port 0 data 1 pin	SPBMI0_n/ SPBIO10_n	I/O	Port 0 master input data/ data 1
	Port 0 data 2 pin	SPBIO20_n	I/O	Port 0 data 2
	Port 0 data 3 pin	SPBIO30_n	I/O	Port 0 data 3
1	Port 1 data 0 pin	SPBMO1_n/ SPBIO01_n	I/O	Port 1 master transmit data/data 0
	Port 1 data 1 pin	SPBMI1_n/ SPBIO11_n	I/O	Port 1 master input data/ data 1
	Port 1 data 2 pin	SPBIO21_n	I/O	Port 1 data 2
	Port 1 data 3 pin	SPBIO31_n	I/O	Port 1 data 3

Note: n represents a channel number (0). In the text, the channel number is omitted.

17.4 Register Descriptions

Table 17.2 shows the register configuration.

Table 17.2 Register Configuration

Channel	Register Name	Abbreviation	Initial Value	R/W	Address	Access Size
0	Common control register_0	CMNCR_0	H'01AA4000	R/W	H'3FEFA000	32

Note: In the text, the channel number is omitted.

17.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the SPI multi I/O bus controller. The settings of this register are reflected both in external address space read mode and SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

23, 22	MOIIO3[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO30, SPBIO31 Fixes output values of SPBIO30 and SPBIO31 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
21, 20	MOIIO2[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO20, SPBIO21 Fixes output values of SPBIO20 and SPBIO21 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
19, 18	MOIIO1[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO10, SPBIO11 Fixes output values of SPBIO10 and SPBIO11 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z

Bit	Bit Name	Initial Value	R/W	Description
17, 16	MOIIO0[1:0]	10	R/W	SPBSSL Output Idle Value Fix SPBIO00, SPBIO01 Fixes output values of SPBIO00 and SPBIO01 in SPBSSL negation period. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
15, 14	IO3FV[1:0]	01	R/W	SPBIO30, SPBIO31 Fixed Value for 1-bit/2-bit Size Fixes the output value of SPBIO30 and SPBIO31 pins for 1-bit/2-bit size. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
13, 12	IO2FV[1:0]	00	R/W	SPBIO20, SPBIO21 Fixed Value for 1-bit/2-bit Size Fixes the output value of SPBIO20 and SPBIO21 pins for 1-bit/2-bit size. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	IO0FV[1:0]	00	R/W	SPBIO00, SPBIO01 Fixed Value for 1-bit Size Input Fixes the output value of SPBIO00 and SPBIO01 pins for 1-bit size input. 00: Output value 0 01: Output value 1 10: Output value is the value of the immediately previous bit (or the pin is Hi-Z, if Hi-Z was the state in the immediately previous bit period). 11: Output value Hi-Z
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	CPHAT	0	R/W	Output Shift Sets the SPBCLK edge of the output data. CPHAT and CPHAR should be set according to the table in the description of CPHAR. 0: Data transmission at even edge during SDR transfer Data transmission starts at even edge during DDR transfer (RZ/A1LU only). 1: Data transmission at odd edge during SDR transfer Data transmission starts at odd edge during DDR transfer (RZ/A1LU only).
5	CPHAR	0	R/W	Input Latch Sets the SPBCLK edge of the reception data. CPHAT and CPHAR should be set according to the following table. 0: Data reception at odd edge during SDR transfer Data reception starts at odd edge during DDR transfer (RZ/A1LU only). 1: Data reception at even edge during SDR transfer Data reception starts at even edge during DDR transfer (RZ/A1LU only).

CPHAT	CPHAR	
0	0	Setting enabled
0	1	Setting enabled
1	0	Setting prohibited
1	1	Setting enabled

Note: To set DDR transfer, set both the CPHAT and CPHAR bits to 0 or 1 (RZ/A1LU only).

Bit	Bit Name	Initial Value	R/W	Description
4	SSLP	0	R/W	SPBSSL Signal Polarity Sets the polarity of SPBSSL signal. 0: Active low SPBSSL signal 1: Active high SPBSSL signal
3	CPOL	0	R/W	SPBSSL Negation Period SPBCLK Output Direction Sets the SPBCLK output direction during SPBSSL negation period. 0: SPBCLK output is 0 during SPBSSL negation period. 1: SPBCLK output is 1 during SPBSSL negation period.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	BSZ[1:0]	00	R/W	Data Bus Size Specifies the number of serial flash memories to be connected. 00: 1 memory 01: 2 memories 1X: Setting prohibited Note: After changing (the value of) this bit, all the entries in the read cache must be cleared by setting the RCF bit in DRCR to 1.

17.4.2 SSL Delay Register (SSLDR)

SSLDR is a 32-bit register that adjusts the timing between the SPBSSL signal and the SPBCLK signal.
The settings of this register are reflected both in external address space read mode and SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	SPNDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SLNDL[2:0]			-	-	-	-	-	SCKDL[2:0]		
Initial value:	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	SPNDL[2:0]	111	R/W	Next Access Delay Sets the period from transfer end to next transfer start (next access). 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	SLNDL[2:0]	111	R/W	SPBSSL Negation Delay Sets the period from the time the last SPBCLK edge is sent of a transfer to SPBSSL pin negation (SPBSSL negation delay). 000: 1.5 SPBCLK cycles 001: 2.5 SPBCLK cycles 010: 3.5 SPBCLK cycles 011: 4.5 SPBCLK cycles 100: 5.5 SPBCLK cycles 101: 6.5 SPBCLK cycles 110: 7.5 SPBCLK cycles 111: 8.5 SPBCLK cycles
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	SCKDL[2:0]	111	R/W	Clock Delay Sets the period from SPBSSL pin assertion to SPBCLK oscillation (clock delay). 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles

17.4.3 Bit Rate Register (SPBCR)

SPBCR is a 32-bit register that sets the bit rate.
The settings of this register are reflected both in external address space read mode and SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPBR[7:0]								-	-	-	-	-	-	BRDV[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	SPBR[7:0]	All 0	R/W	Bit Rate Sets the bit rate. The bit rate is determined by a combination of these bits with the BRDV[1:0] bits. For details, see Table 17.3, Relationship between SPBR[7:0] and BRDV[1:0] Settings.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	BRDV[1:0]	11	R/W	Bit Rate Frequency Division Sets the bit rate. The bit rate is determined by a combination of these bits with the SPBR[7:0] bits. The SPBR value is used to set the base bit rate. The BRDV value is used to select a division ratio of the base bit rate from among no division, 2, 4, and 8. 00: Base bit rate 01: Base bit rate divided by 2 10: Base bit rate divided by 4 11: Base bit rate divided by 8

(1) Bit Rate

SPBR[7:0] and BRDV[1:0] are used for setting the bit rate.

The following formula is used to calculate the bit rate when SPBR[7:0] ≠ 0.

Bit rate = Bϕ / (2 × n × 2^N)
n: SPBR[7:0] setting (1, …, 255)
N: BRDV[1:0] setting (0 to 3)

Also the following formula is used to calculate the bit rate when SPBR[7:0] = 0.

Bit rate = Bϕ /2^N
N: BRDV[1:0] setting (0 to 3)

Table 17.3 Relationship between SPBR[7:0] and BRDV[1:0] Settings

			Bit Rate		
SPBR[7:0] (n)	**BRDV[1:0] (N)**	**Division Ratio**	**Bϕ = 100 MHz**	**Bϕ = 128 MHz**	**Bϕ = 133.33 MHz**
0	0	1	Setting prohibited		
1	0	2	50 Mbps	64 Mbps	66.67 Mbps
2	0	4	25 Mbps	32 Mbps	33.33 Mbps
3	0	6	16.67 Mbps	21.33 Mbps	22.22 Mbps
4	0	8	12.5 Mbps	16 Mbps	16.67 Mbps
5	0	10	10 Mbps	12.8 Mbps	13.33 Mbps
6	0	12	8.33 Mbps	10.67 Mbps	11.11 Mbps
6	1	24	4.17 Mbps	5.33 Mbps	5.56 Mbps
6	2	48	2.08 Mbps	2.67 Mbps	2.78 Mbps
6	3	96	1.04 Mbps	1.33 Mbps	1.39 Mbps
255	3	4080	24.51 Kbps	31.37 Kbps	32.68 Kbps

Note: The bit rate should be set so that it will satisfy the AC characteristics of this module.

17.4.4 Data Read Control Register (DRCR)

DRCR is a 32-bit register that sets the operation in external address space read mode.
The bits except the SSLN bit should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	SSLN	-	-	-	-	RBURST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	W	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	RCF	RBE	-	-	-	-	-	-	-	SSLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	SSLN	0	W	SPBSSL Negation Asserted SPBSSL can be negated by writing 1 to this bit when both the RBE and SSLE bits are 1. This bit is always read as 0. Note: To start next access after SPBSSL negation using this bit, read SSLF in CMNSR = 0 to confirm that the SPBSSL has been negated.
23 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	RBURST [3:0]	0000	R/W	Read Data Burst Length Sets the burst length (data unit count) when reading. This bit is enabled when the RBE bit is set to 1. 0000: 1 data unit 0001: 2 continuous data units : 1110: 15 continuous data units 1111: 16 continuous data units One data unit is 64 bits long.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	RCF	0	W	Read Cache Flush When 1 is written to this bit, all the entries in the read cache are cleared. This bit is always read as 0. Note: After flushing the read cache by writing 1 to the RCF bit, read the DRCR before proceeding to read from the external address space.
8	RBE	0	R/W	Read Burst Turns burst ON or OFF when reading. 0: Data is read according to the access size. 1: Read cache is enabled, and as many data units as the burst count specified in RBURST[3:0] bits is read.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SSLE	0	R/W	SPBSSL Negation Sets the conditions for SPBSSL negation during read burst. SPBSSL is negated for each access during normal read. 0: SPBSSL is negated after transfer of data set in burst length. 1: SPBSSL is negated when the accessed address is not continuous with the previously transferred address.

17.4.5 Data Read Command Setting Register (DRCMR)

DRCMR is a 32-bit register that sets the commands issued in external address space read mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	CMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	OCMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	CMD[7:0]	H'03	R/W	Command Sets the command.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	OCMD[7:0]	H'00	R/W	Optional Command Sets the optional command.

17.4.6 Data Read Extended Address Setting Register (DREAR)

DREAR is a 32-bit register that sets the address when the serial flash address is output in 32-bit mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	EAV[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	EAC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	EAV[7:0]	H'00	R/W	32-Bit Extended Upper Address Fixed Value Sets the upper address bit values of the external address specified by the EAC[2:0] bits when the serial flash address is output in 32-bit mode. Bit 0 corresponds to the serial flash address bit [25], and bit 7 corresponds to the bit [32]. This setting is valid when the ADE[3] bit in DRENR is 1. When EAC[2:0] are 000, serial flash address [32:25] fixed values should be set to EAV[7:0]. When EAC[2:0] are 001, serial flash address [32:26] fixed values should set to EAV[7:1]. (1) When BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) Serial flash addresses [31:0] are used for accessing. (2) When BSZ[1:0] in CMNCR = 01 (two serial flash memories connected) Serial flash addresses [32:1] are used for accessing.
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	EAC[2:0]	000	R/W	32-Bit Extended External Address Valid Range Sets the range of the external address to be used as serial flash address when the serial flash address is output in 32-bit mode. This setting is valid when the ADE[3] bit in DRENR is 1. 000: External address bits [24:0] enabled 001: External address bits [25:0] enabled Other than above: Setting prohibited

17.4.7 Data Read Option Setting Register (DROPR)

DROPR is a 32-bit register that sets the option data in external address space read mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OPD3[7:0]								OPD2[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OPD1[7:0]								OPD0[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

17.4.8 Data Read Enable Setting Register (DRENR)

DRENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and read data in external address space read mode and enables outputting them other than read data.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDB[1:0]		OCDB[1:0]		-	-	ADB[1:0]		-	-	OPDB[1:0]		-	-	DRDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W

R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	00	R/W	Command Bit Size Sets the command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
29, 28	OCDB[1:0]	00	R/W	Optional Command Bit Size Sets the optional command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ADB[1:0]	00	R/W	Address Bit Size Sets the address size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	OPDB[1:0]	00	R/W	Option Data Bit Size Sets the option data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	DRDB[1:0]	00	R/W	Data Read Bit Size Sets the data read size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
15	DME	0	R/W	Dummy Cycle Enable Enables insertion of the dummy cycle before the read data. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled

Bit	Bit Name	Initial Value	R/W	Description
14	CDE	1	R/W	Command Enable Sets the command to be output. 0: Command output disabled 1: Command output enabled
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	OCDE	0	R/W	Optional Command Enable Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled
11 to 8	ADE[3:0]	0111	R/W	Address Enable Sets the address to be output. Be sure to use the following setting; otherwise, the operation is not guaranteed. (1) BSZ[1:0] in CMNCR = 00 (one serial flash memory connected) 0000: Output disabled 0111: Address[23:0] 1111: Address[31:0] Other than above: Setting prohibited (2) BSZ[1:0] in CMNCR = 01 (two serial flash memories connected) 0000: Output disabled 0111: Address[24:1] 1111: Address[32:1] Other than above: Setting prohibited
7 to 4	OPDE[3:0]	0000	R/W	Option Data Enable Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

17.4.9 SPI Mode Control Register (SMCR)

SMCR is a 32-bit register that sets the operation in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SSLKP	-	-	-	-	-	SPIRE	SPIWE	SPIE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SSLKP	0	R/W	SPBSSL Signal Level Determines the SPBSSL status after the end of transfer. 0: SPBSSL signal is negated at the end of transfer. 1: SPBSSL signal level is maintained from the end of transfer to the start of next access.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	SPIRE	0	R/W	Data Read Enable Enables reading in SPI operating mode. 0: Data reading disabled 1: Data reading enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.
1	SPIWE	0	R/W	Data Write Enable Enables writing in SPI operating mode. 0: Data writing disabled 1: Data writing enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.
0	SPIE	0	W	SPI Data Transfer Enable Data is transferred by setting this bit to 1. This bit is enabled only when the TEND bit in CMNSR is set to 1. The operation cannot be guaranteed when this bit is set to 1 with the TEND bit set to 0. This bit is always read as 0. Note: When the SPBSSL pin is de-asserted, the command, optional command, address, and option data that are output enabled are output even if the SPIRE and SPIWE bits are set to 0. When the SPBSSL pin is asserted, follow the notes described in section 17.6.2, Notes on Starting Transfer from the SPBSSL Retained State in SPI Operating Mode.

17.4.10 SPI Mode Command Setting Register (SMCMR)

SMCMR is a 32-bit register that sets the commands issued in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	CMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	OCMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	CMD[7:0]	H'00	R/W	Command Sets the command.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	OCMD[7:0]	H'00	R/W	Optional Command Sets the optional command.

17.4.11 SPI Mode Address Setting Register (SMADR)

SMADR is a 32-bit register that sets the addresses in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR[31:24]								ADR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADR[31:24]	H'00	R/W	Address Sets the value of bits 31 to 24 when the serial flash address is output in 32-bit units. This setting is valid when ADE[3] in SMENR is 1.
23 to 0	ADR[23:0]	H'000000	R/W	Address Sets the address.

17.4.12 SPI Mode Option Setting Register (SMOPR)

SMOPR is a 32-bit register that sets the option data in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OPD3[7:0]								OPD2[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OPD1[7:0]								OPD0[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	OPD3[7:0]	H'00	R/W	Option Data 3 Sets the option data 3.
23 to 16	OPD2[7:0]	H'00	R/W	Option Data 2 Sets the option data 2.
15 to 8	OPD1[7:0]	H'00	R/W	Option Data 1 Sets the option data 1.
7 to 0	OPD0[7:0]	H'00	R/W	Option Data 0 Sets the option data 0.

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

17.4.13 SPI Mode Enable Setting Register (SMENR)

SMENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and transfer data in SPI operating mode and enables their output. SMENR also enables dummy cycle insertion. Disabling all of the command, optional command, address, option data, dummy cycle, and transfer data is prohibited. At least one of them except dummy cycle must be enabled.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDB[1:0]		OCDB[1:0]		-	-	ADB[1:0]		-	-	OPDB[1:0]		-	-	SPIDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W

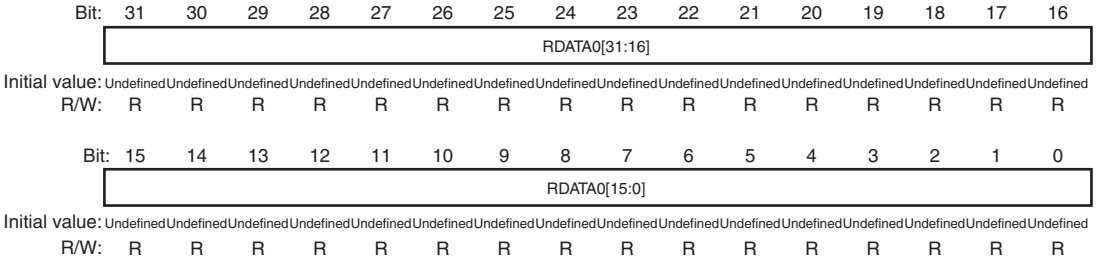
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	CDB[1:0]	00	R/W	Command Bit Size Sets the command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
29, 28	OCDB[1:0]	00	R/W	Optional Command Bit Size Sets the optional command size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ADB[1:0]	00	R/W	Address Bit Size Sets the address size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	OPDB[1:0]	00	R/W	Option Data Bit Size Sets the option data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	SPIDB[1:0]	00	R/W	Transfer Data Bit Size Sets the transfer data size in bit units. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
15	DME	0	R/W	Dummy Cycle Enable Enables insertion of the dummy cycle before the read data. Note: Dummy cycle insertion is prohibited for write in SPI operating mode including the case in which a transfer ends with a dummy cycle. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled
14	CDE	1	R/W	Command Enable Sets the command to be output. 0: Command output disabled 1: Command output enabled
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	OCDE	0	R/W	Optional Command Enable Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled
11 to 8	ADE[3:0]	0000	R/W	Address Enable Sets the address to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 0100: ADR[23:16] 0110: ADR[23:8] 0111: ADR[23:0] 1111: ADR[31:0] Other than above: Setting prohibited
7 to 4	OPDE[3:0]	0000	R/W	Option Data Enable Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited
3 to 0	SPIDE[3:0]	0000	R/W	Transfer Data Enable Sets valid transfer data. Valid data differs depending on the BSZ[1:0] bit setting in CMNCR. The following settings must be used. Otherwise, the operation is not guaranteed. (1) BSZ[1:0] bits in CMNCR = 00 (one serial flash memory connected) 0000: Not transferred 1000: 8 bits transferred (enables data at address 0 of the SPI mode read/write data registers 0) 1100: 16 bits transferred (enables data at addresses 0 and 1 of the SPI mode read/write data registers 0) 1111: 32 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0) Other than above: Setting prohibited (2) BSZ[1:0] bits in CMNCR = 01 (two serial flash memories connected) 0000: Not transferred 1000: 16 bits transferred (enables data at addresses 0 and 1 of the SPI mode read/write data registers 0) 1100: 32 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0) 1111: 64 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0 and data at addresses 0 to 3 of the SPI mode read/write data registers 1) Other than above: Setting prohibited

17.4.14 SPI Mode Read Data Register 0 (SMRDR0)

SMRDR0 is a 32-bit register that stores the read data in SPI operating mode.
Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.
The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

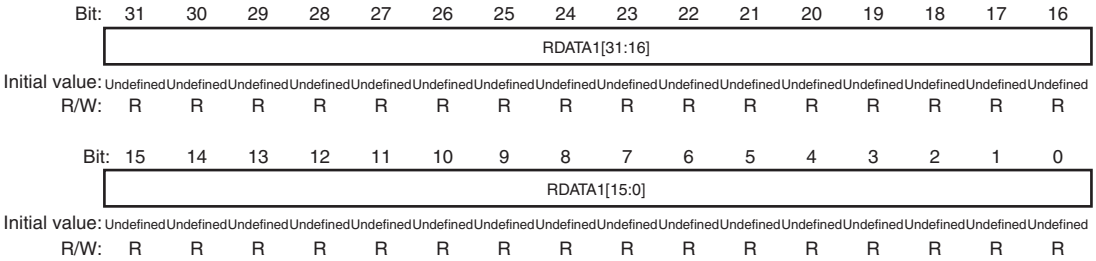


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA0 [31:0]	Undefined	R	Read Data Holds the data read in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Read data[63:32]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Read data[31:0]. Other than the above: Read data[31:0].

Note: The contents of this register and SMRDR1 are modified upon completion of reception in SPI operating mode. Be sure to read data when reception in SPI operating mode is completed.

17.4.15 SPI Mode Read Data Register 1 (SMRDR1)

SMRDR1 is a 32-bit register that stores the read data in SPI operating mode.
This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 (two serial flash memories connected) and disabled when the BSZ[1:0] bits in CMNCR are set to 00 (one serial flash memory connected).
Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.
The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDATA1 [31:0]	Undefined	R	Read Data Holds the data read in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Read data[31:0]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Read data[63:32]. Other than the above: Bits in this register are disabled.

17.4.16 SPI Mode Write Data Register 0 (SMWDR0)

SMWDR0 is a 32-bit register that sets the write data in SPI operating mode.
Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA0 [31:0]	All 0	R/W	Write Data Holds the data to be written in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Write data[63:32]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Write data[31:0]. Other than the above: Write data[31:0].

17.4.17 SPI Mode Write Data Register 1 (SMWDR1)

SMWDR1 is a 32-bit register that sets the write data in SPI operating mode.
This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 (two serial flash memories connected) and disabled when the BSZ[1:0] bits in CMNCR are set to 00 (one serial flash memory connected).
Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the SPI mode enable setting register (SMENR). Be sure to access from address 0.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	WDATA1 [31:0]	All 0	R/W	Write Data Holds the data to be written in SPI operating mode. Data bits differ depending on the settings of SFDE and BSZ[1:0] bits in CMNCR and SPIDE[3:0] bits in SMENR. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 1: Write data[31:0]. BSZ[1:0] = 01, SPIDE[3:0] = 1111, SFDE = 0: Write data[63:32]. Other than the above: Bits in this register are disabled.

17.4.18 Common Status Register (CMNSR)

CMNSR is a 32-bit register that holds flags indicating the operating state.

The settings of this register are reflected both in external address space read mode and SPI operating mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SSLF	TEND
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	SSLF	0	R	SPBSSL Pin Monitor 0: SPBSSL pin is negated 1: SPBSSL pin is asserted
0	TEND	1	R	Transfer End Flag Indicates whether the data transfer has ended. 0: Indicates that data transfer is in progress 1: Indicates that data transfer has ended

17.4.19 SPI AC Input Characteristics Adjustment Register (CKDLY) (RZ/A1LU only)

CKDLY is used to adjust the timing of the setup and hold times for data input. The timing should be adjusted to suit the AC characteristics of the serial flash memory to be connected. Settings of this register should be changed while the SSLF flag in CMNSR is 0; otherwise, the operation cannot be guaranteed. When writing, write to the register as a 32-bit unit with bits 15 to 8 set to H'A5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GB[7:0]								-	-	-	-	CKDLY[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W:	W	W	W	W	W	W	W	W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	GB[7:0]	All 0	W	Guard When writing, write to the register as a 32-bit unit with these bits set to H'A5. These bits are always read as 0.
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CKDLY[3:0]	0100	R/W	Input Characteristics Adjustment Switches the relative timing of the setup and hold times for data input. The two values below are specifiable. 0100: Initial value 1010: Makes the data input setup time shorter and the data input hold time longer. Other than the above: Settings prohibited

17.4.20 Data Read Dummy Cycle Setting Register (DRDMCR)

DRDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in external address space read mode.

The settings of this register are enabled when the DME bit in the data read enable setting register (DRENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DMDB[1:0]

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	DMDB [1:0]	00	R/W	Dummy Cycle Bit Size Sets the dummy cycle size in bit units. The setting of these bits is combined with the setting of the IO0FV, IO2FV, and IO3FV bits in the common control register (CMNCR) to determine the state of the unused pins during the dummy cycles. The state of the used pins is Hi-Z. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	DMCYC [2:0]	000	R/W	Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the data read enable setting register (DRENR) is 1. 000: 1 cycle 001: 2 cycles 010: 3 cycles 011: 4 cycles 100: 5 cycles 101: 6 cycles 110: 7 cycles 111: 8 cycles

17.4.21 Data Read DDR Enable Register (DRDRENR) (RZ/A1LU only)

DRDRENR is a 32-bit register that sets SDR or DDR transfer of the address, option data, and read data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ADDRE	0	R/W	Address DDR Enable Sets SDR or DDR transfer of the address. 0: SDR transfer 1: DDR transfer
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OPDRE	0	R/W	Option Data DDR Enable Sets SDR or DDR transfer of the option data. 0: SDR transfer 1: DDR transfer
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DRDRE	0	R/W	Data Read DDR Enable Sets SDR or DDR transfer of the read data. 0: SDR transfer 1: DDR transfer

17.4.22 SPI Mode Dummy Cycle Setting Register (SMDMCR)

SMDMCR is a 32-bit register that sets the size and number of dummy cycles to be inserted in SPI operating mode.
The settings of this register are enabled when the DME bit in the SPI mode enable setting register (SMENR) is 1.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	DMDB[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DMCYC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17 and 16	DMDB [1:0]	00	R/W	Dummy Cycle Bit Size Sets the dummy cycle size in bit units. The setting of these bits is combined with the setting of the IO0FV, IO2FV, and IO3FV bits in the common control register (CMNCR) to determine the state of the unused pins during the dummy cycles. The state of the used pins is Hi-Z. 00: 1 bit 01: 2 bits 10: 4 bits 11: Setting prohibited
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	DMCYC[2:0]	000	R/W	Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the SPI mode enable setting register (SMENR) is 1. 000: 1 cycle 001: 2 cycles 010: 3 cycles 011: 4 cycles 100: 5 cycles 101: 6 cycles 110: 7 cycles 111: 8 cycles

17.4.23 SPI Mode DDR Enable Register (SMDRENR) (RZ/A1LU only)

SMDRENR is a 32-bit register that sets SDR or DDR transfer of the address, option data, and transfer data in SPI operating mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	ADDRE	-	-	-	OPDRE	-	-	-	SPIDRE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ADDRE	0	R/W	Address DDR Enable Sets SDR or DDR transfer of the address. 0: SDR transfer 1: DDR transfer
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OPDRE	0	R/W	Option Data DDR Enable Sets SDR or DDR transfer of the option data. 0: SDR transfer 1: DDR transfer
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SPIDRE	0	R/W	Transfer Data DDR Enable Sets SDR or DDR transfer of the transfer data. 0: SDR transfer 1: DDR transfer

17.4.24 SPI AC Output Characteristics Adjustment Register (SPODLY) (RZ/A1LU only)

SPODLY is used to adjust the timing of the delay, hold, buffer on and buffer off times for data output. The timing should be adjusted to suit the AC characteristics of the serial flash memory to be connected. Settings of this register should be changed while the SSLF flag in CMNSR is 0; otherwise, the operation cannot be guaranteed. When writing, write to the register as a 32-bit unit with bits 31 to 24 set to H'A5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GB[7:0]								-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPODLY[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	GB[7:0]	All 0	W	Guard When writing, write to the register as a 32-bit unit with these bits set to H'A5. These bits are always read as 0.
23 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	SPODLY[15:0]	All 0	R/W	Output Characteristics Adjustment Switches the timing of the delay, hold, buffer on and buffer off times for data output. The two values below are specifiable. H'0000: Initial value H'1111: The delay, hold, buffer on and buffer off times for data output are lengthened. Other than the above: Settings prohibited

17.5 Operation

17.5.1 System Configuration

With this module, one or two serial flash memories can be directly connected per channel (data size of 1, 2, and 4 bits). The number of connected memories can be selected using the BSZ[1:0] bits in CMNCR.

Examples of system configuration with one serial flash memory connected and two serial flash memories connected are shown in Figure 17.2 and Figure 17.3, respectively.

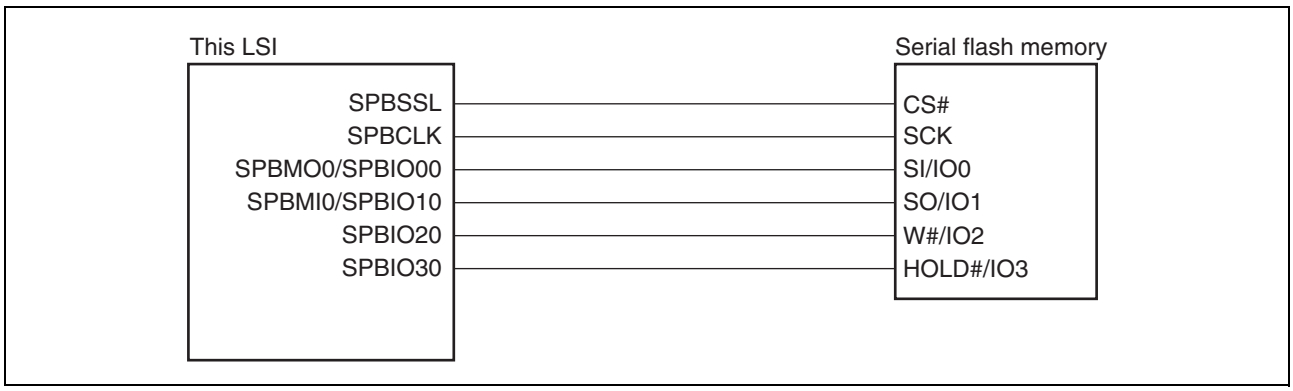

Figure 17.2 System Configuration Example with 4-Bit Data Size and One Serial Flash Memory Connected (BSZ[1:0] Bits in CMNCR = 00)

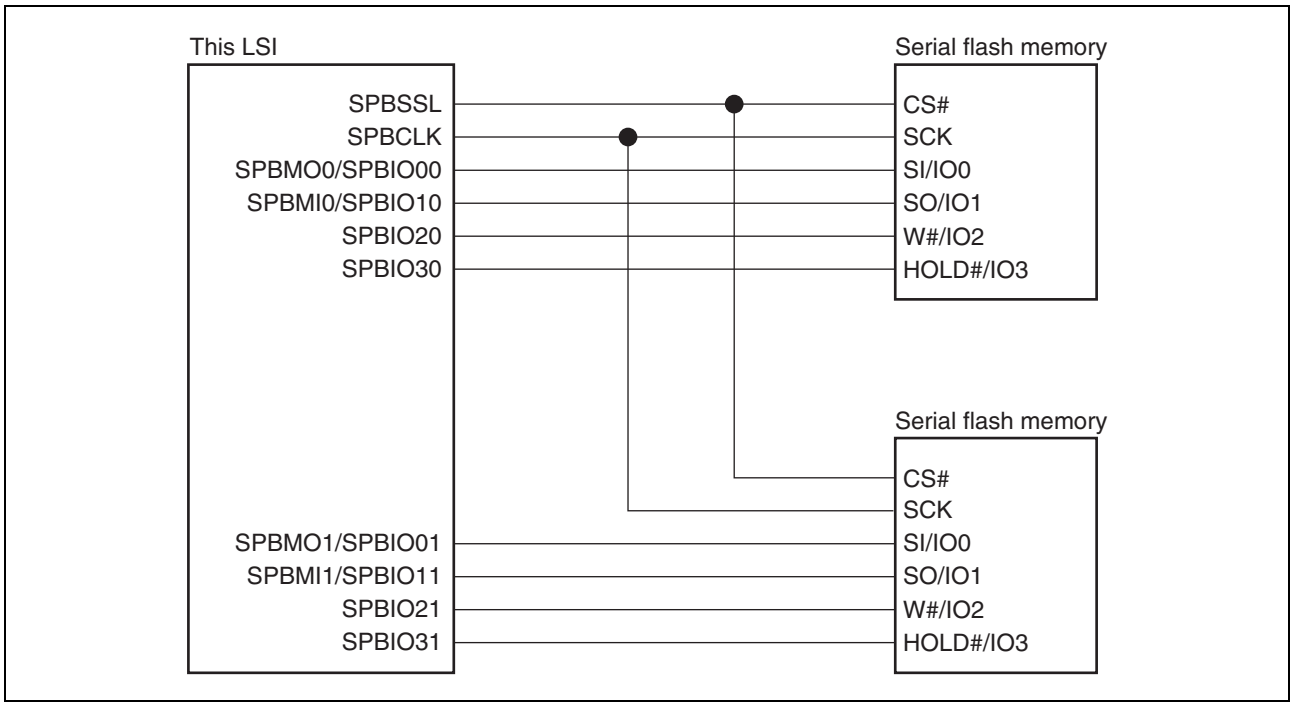

Figure 17.3 System Configuration Example with 4-Bit Data Size and Two Serial Flash Memories Connected (BSZ[1:0] Bits in CMNCR = 01)

17.5.2 Address Map

In external address space read mode, the serial flash connected is assigned in the SPI multi I/O bus space. A maximum accessible address space differs depending on the number of serial flash memories connected. In combination with DREAR, a maximum of 4 Gbytes can be accessed when one serial flash memory is connected, and a maximum of 8 Gbytes can be accessed when two memories are connected.

Table 17.4 Address Map

Channel	Number of Serial Flash Memories Connected	Internal Address	Max. Access Area
0	1	H'18000000 to H'1BFFFFFF	4 Gbytes
		H'58000000 to H'5BFFFFFF (mirror area)	
	2	H'18000000 to H'1BFFFFFF	8 Gbytes
		H'58000000 to H'5BFFFFFF (mirror area)	

17.5.3 32-bit Serial Flash Addresses

Since the SPI multi I/O bus space is 64 Mbytes, only a part of the 32-bit serial flash address area can be directly accessed. Here, the fixed value set in the pertinent register is used as the upper bit value of a 32-bit address.
To output serial flash addresses in 32 bits, set the ADE[3] bit in DRENR to 1, set the range of the external addresses used as the serial flash addresses to the EAC[2:0] bits in DREAR, and set the upper bit value of the 32-bit address as the fixed value to the EAV[7:0] bits in DREAR.

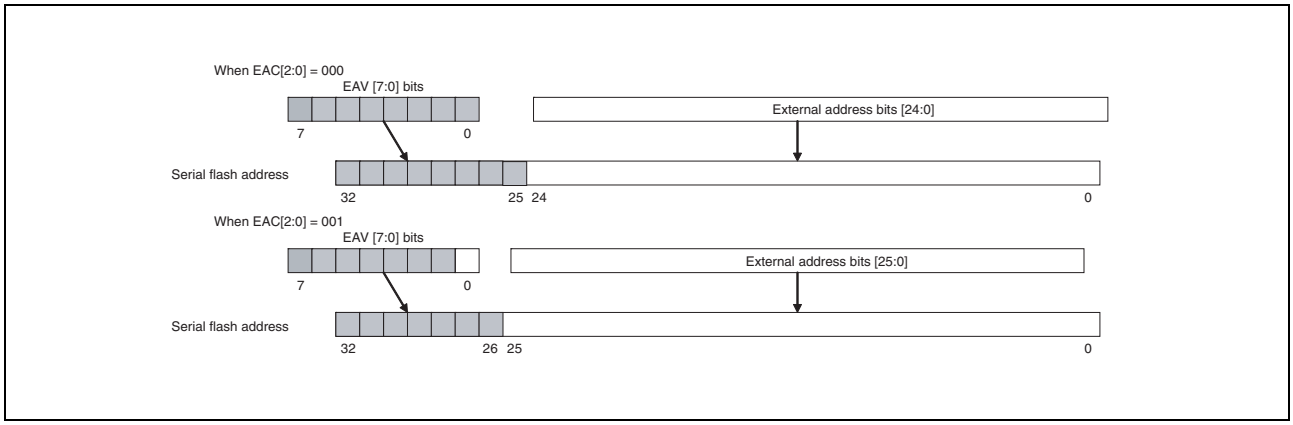

Figure 17.4 32-Bit Address Setting

Setting the ADE[3] bit in DRENR to 1 allows the serial flash address to be output using [31:0] bits. When EAC[2:0] = 000, external address bits [24:0] are valid; set the value for [32:25] bits to EAV[7:0]. When EAC[2:0] = 001, external address bits [25:0] are valid; set the value for [32:26] bits to EAV[7:1].
The address bits actually used for access depend on the number of serial flash memories connected. When one serial flash memory is connected, address bits [31:0] are used and when two memories are connected, address bits [32:1] are used.

Note: When the capacity of the serial flash memory used is smaller than 4 Gbytes, keep the following point in mind. If an access spreads over the last address of the serial flash in burst mode (RBE bit in DRCR = 1), the access address does not agree with the internal address of the serial flash. To prevent this, software should appropriately manage the accessible address areas for the serial flash memory used according to the memory capacity.

17.5.4 Data Alignment

Data alignment can be set by using the SFDE bit in the common control register (CMNCR). Data alignment in data read mode and in SPI mode are shown in Figure 17.5 and Figure 17.6, respectively.

When two serial flash memories are connected, the serial flash memory connected to the pin SPBIO30-SPBIO00 has the address 2n and the serial flash memory connected to the pin SPBIO31-SPBIO01 has the address 2n + 1. The data should be accessed in word or larger units. It cannot be accessed in byte units.

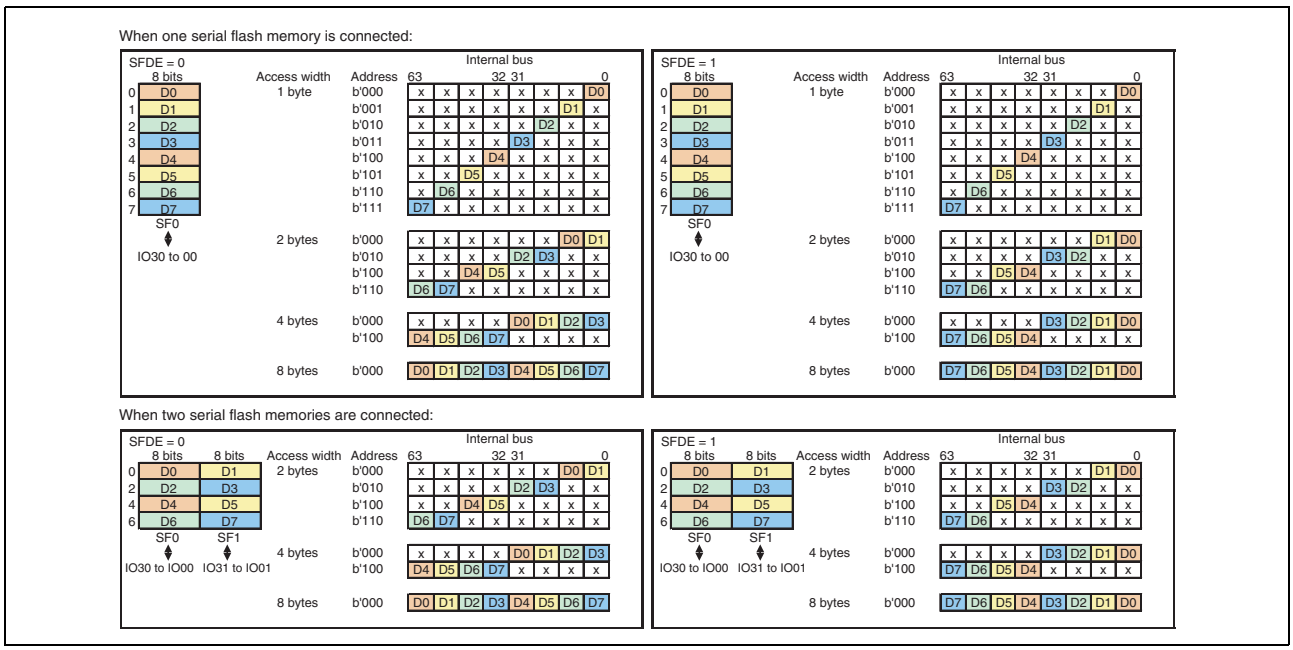

Figure 17.5 Data Alignment in Data Read Mode

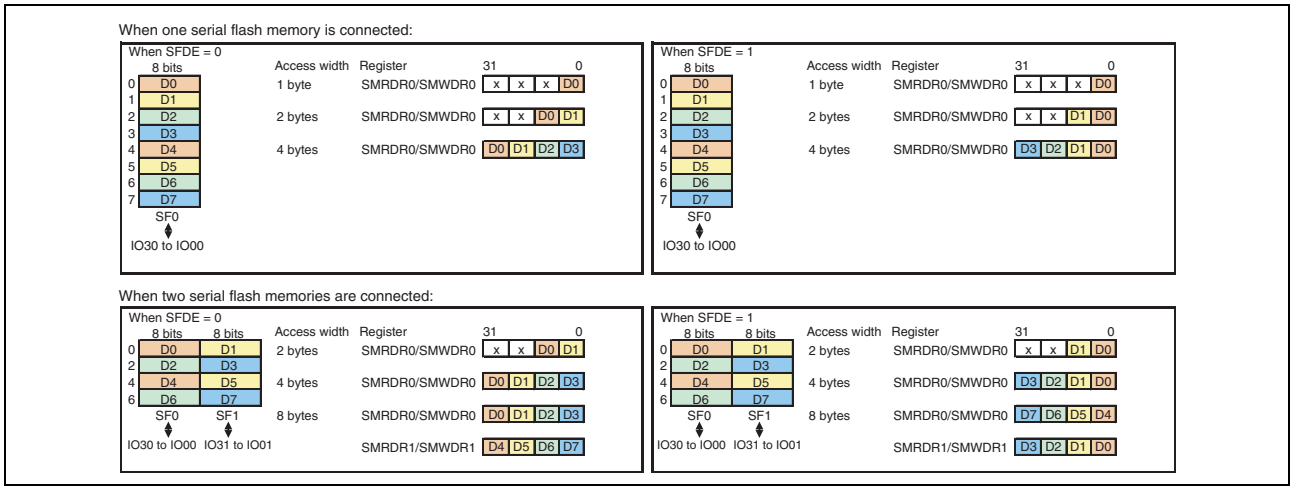

Figure 17.6 Data Alignment in SPI Mode

17.5.5 Operating Modes

This module has two operating modes: external address space read mode and SPI operating mode.
In external address space read mode, a read access to the SPI multi I/O bus space is converted into SPI communication and data is received. After data acquisition, data is returned to the bus master that is the issuing source. For details, see section 17.5.6, External Address Space Read Mode.
In SPI operating mode, arbitrary SPI communication is carried out using register settings. For details, see section 17.5.8, SPI Operating Mode.

17.5.6 External Address Space Read Mode

A read access to the SPI multi I/O bus space can be converted into SPI communication in external address space read mode. Further, the commands, optional commands, option data, and dummy cycle issued for reading can be modified using registers.
For the address, option data, and read data, either SDR or DDR transfer can be selected using the appropriate register when the SPBCLK frequency division ratio is two or larger (RZ/A1LU only).
In external address space read mode, either normal read operation or burst read operation can be selected. The transfer format is determined based on the following registers.
- Common control register (CMNCR)
- SSL delay register (SSLDR)
- Bit rate setting register (SPBCR)
- Data read control register (DRCR)
- Data read command setting register (DRCMR)
- Data read extended address setting register (DREAR)
- Data read option setting register (DROPR)
- Data read enable setting register (DRENR)
- Data read dummy cycle setting register (DRDMCR).
- Data read DDR enable register (DRDRENR)*

Note: * RZ/A1LU only

(1) Normal Read Operation

When the RBE bit in DRCR is set to 0, normal read operation is performed.
In the normal read operation, the data of 8 bits, 16 bits, 32 bits, and 64 bits are read for respectively a byte, a word, and a longword read access. Here, a byte access is enabled only when one serial flash memory is connected. After reading, the SPBSSL pin is negated.
The normal read operation timing is shown in Figure 17.7.
t1 is the time period from SPBSSL pin assertion to SPBCLK oscillation (clock delay), t2 is the time period from transmission of the last SPBCLK edge of a transfer to SPBSSL pin negation (SPBSSL negation delay), and t3 is the time period from one transfer end to the next transfer start (next access). For details of t1, t2, and t3, see section 17.5.9, Transfer Format.

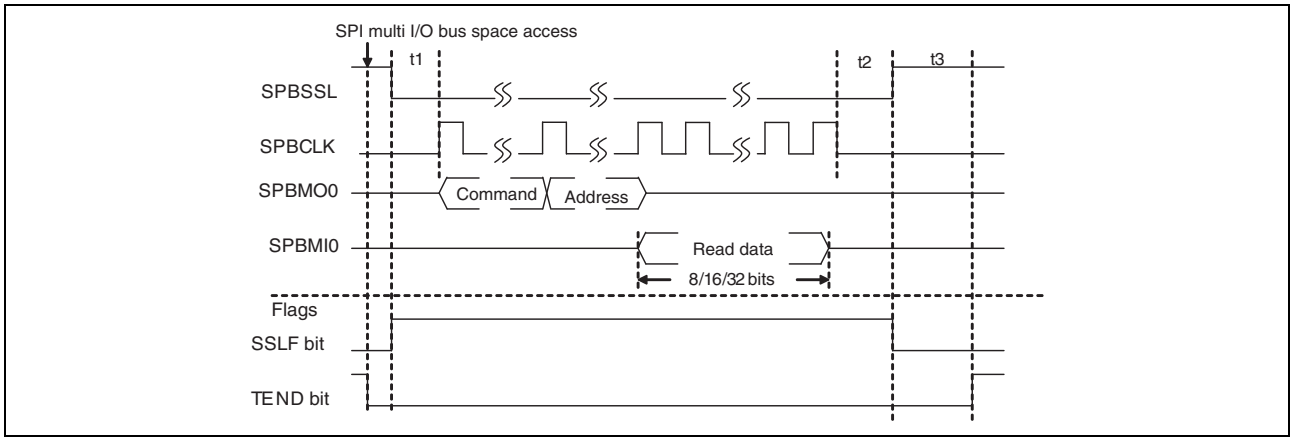

Figure 17.7 Normal Read Operation Timing

(2) Burst Read Operation

When the RBE bit in DRCR is set to 1, burst read operation is performed.
Read cache is enabled in the burst read operation. For read cache operation, see section 17.5.7, Read Cache.
For reading bytes, words, or longwords, the read cache is first referred to for the data. When the read cache contains the data, the data is read from the read cache without accessing the serial flash memory. When the read cache does not contain the data, burst read operation is performed in the serial flash memory and the read data is stored in the read cache. The data transfer length at that time is 64 bits × RBURST[3:0] bits and the data is always read from the 64-bit boundary.
The SPBSSL pin status after data transfer can be selected by using the SSLE bit in DRCR. When the SSLE bit is set to 0, the SPBSSL pin is negated after data transfer. For an operation performed when the SSLE bit is set to 1, see (3) Burst Read Operation with Automatic SPBSSL Negation, just below.
A pattern diagram of this operation and a burst read operation timing diagram when SSLE bit is set to 0 are shown in Figure 17.8 and Figure 17.9.

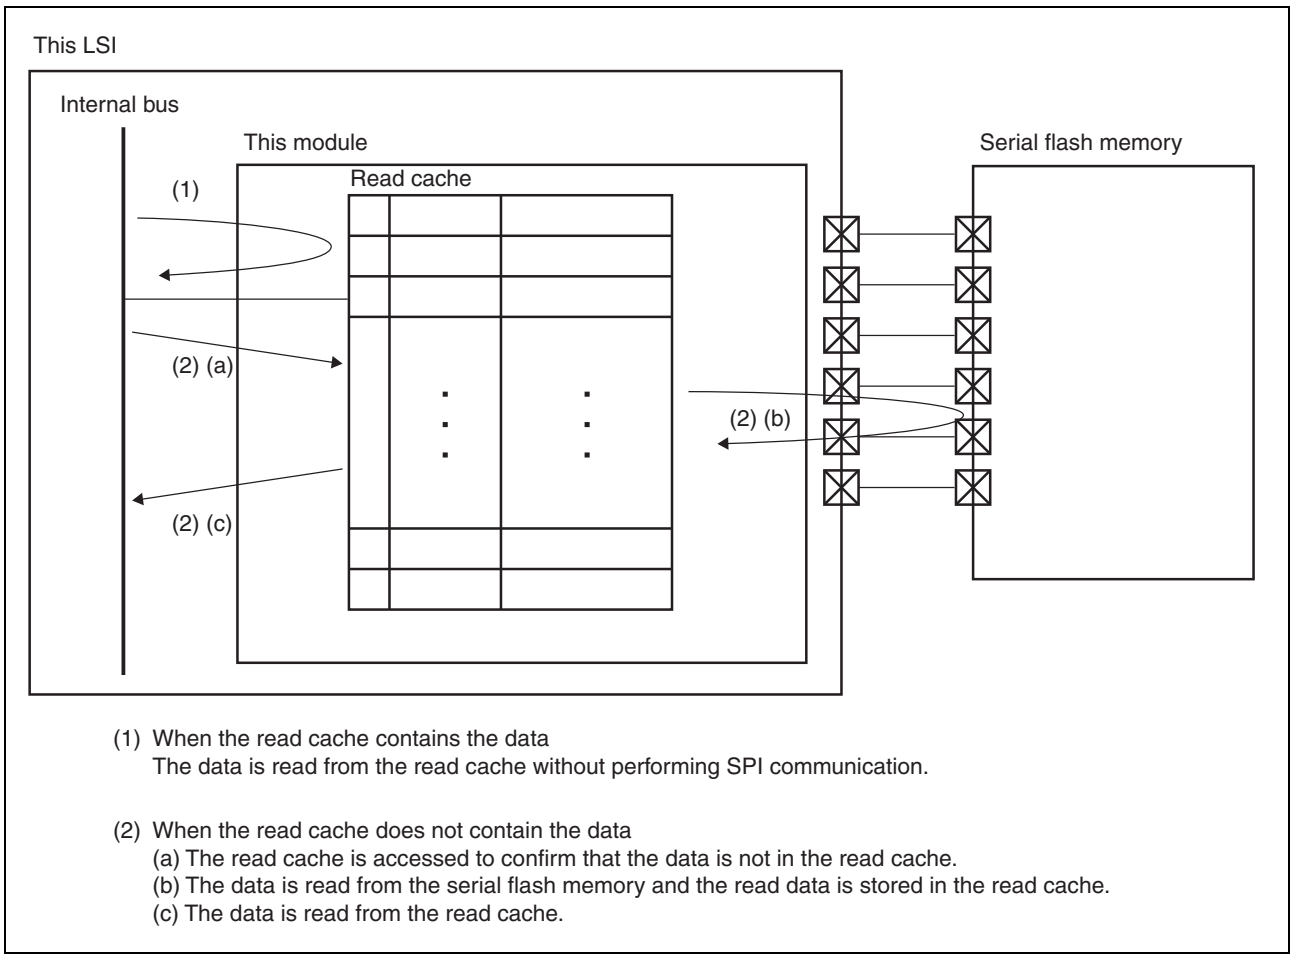

Figure 17.8 Burst Read Operation

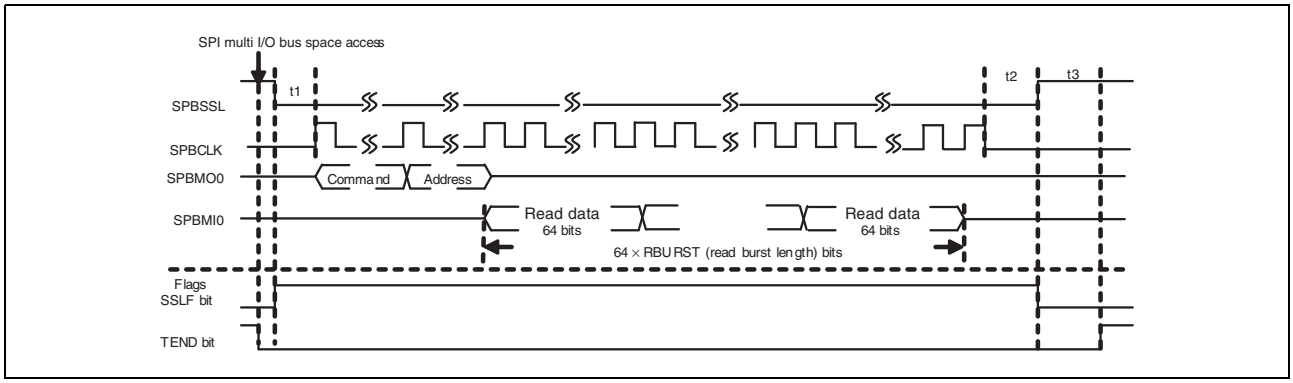

Figure 17.9 Burst Read Operation Timing (SSLE Bit = 0)

(3) Burst Read Operation with Automatic SPBSSL Negation

When SSLE bit in DRCR is set to 1, this module does not negate the SPBSSL pin after the burst read transfer. When accessing the next time, if the address is continuous with the previous read address, the burst read operation is performed without issuing the command, optional command, address, option data, or dummy cycle. If the address is not continuous with the previous read address, the SPBSSL pin is once negated and the burst read operation is performed after issuing the command, optional command, address, option data, or dummy cycle.

Burst read timing diagrams for continuous address and non-continuous address are shown in Figure 17.10 and Figure 17.11.

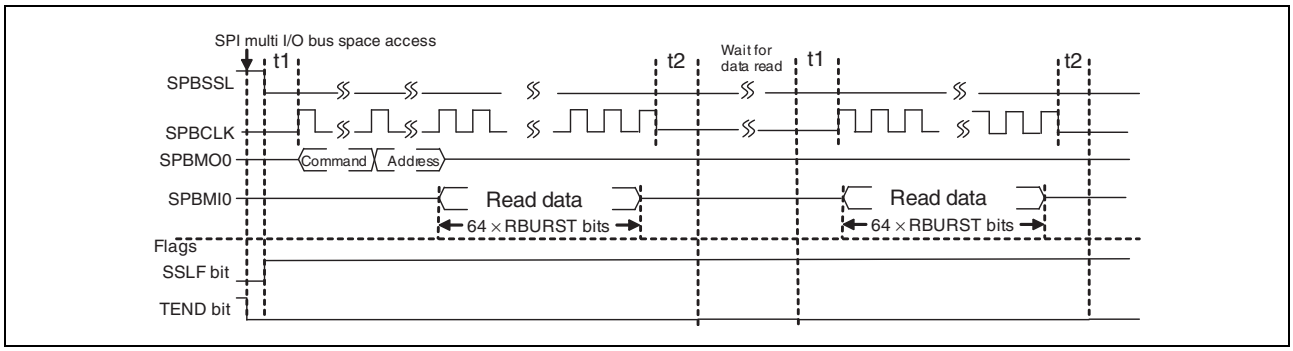

Figure 17.10 Burst Read Timing for Continuous Address (SSLE Bit = 1)

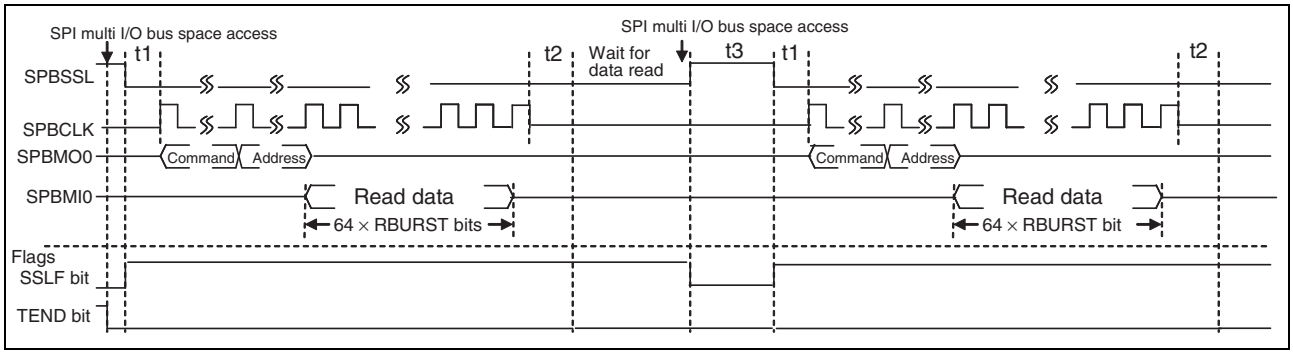

Figure 17.11 Burst Read Timing for Non-Continuous Address (SSLE Bit = 1)

For the next access after negation of the SPBSSL with the SSLN bit in DRCR with this operation, read SSLF = 0 in CMNSR to confirm that the SPBSSL has been negated.

(4) Initial Setting Flow

An example of an initial setting flow in external address space read mode is shown in Figure 17.12.

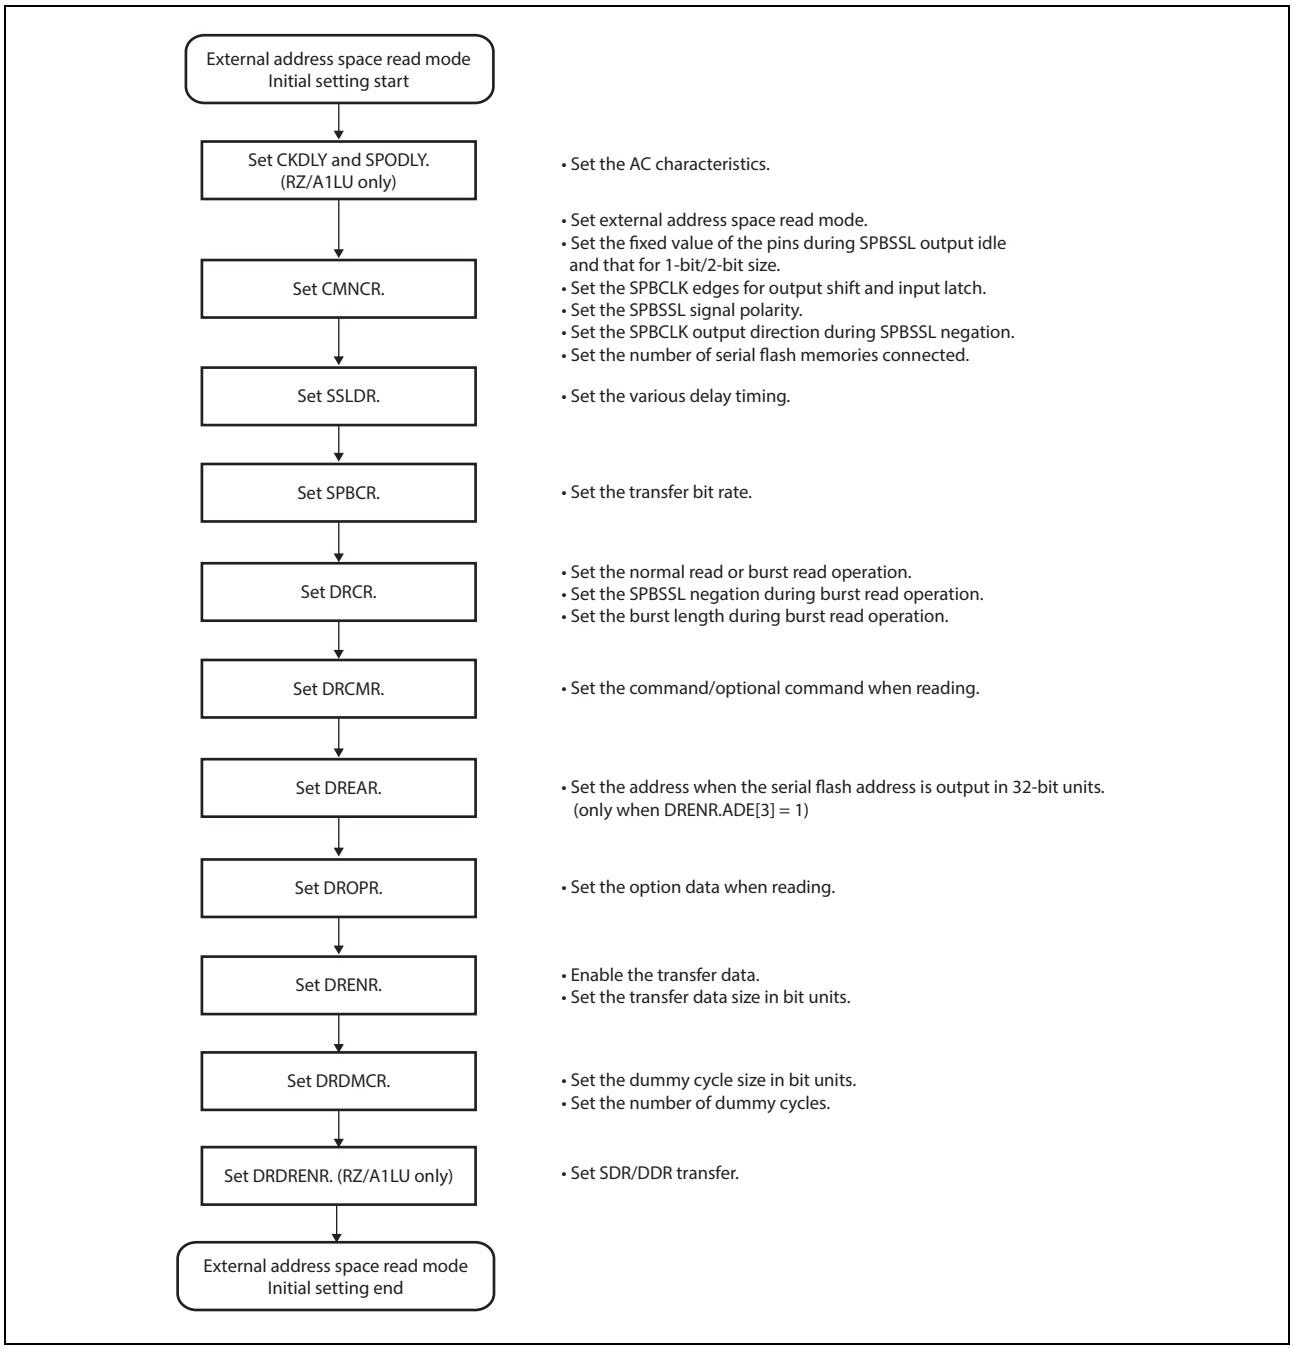

Figure 17.12 Example of Initial Setting Flow in External Address Space Read Mode

17.5.7 Read Cache

This module has a simple built-in read cache. The read cache can be used during external address space read mode and burst read operation. The read cache is configured with a line size of 64 bits and 16 entries.
Read cache configuration is shown in Figure 17.13.

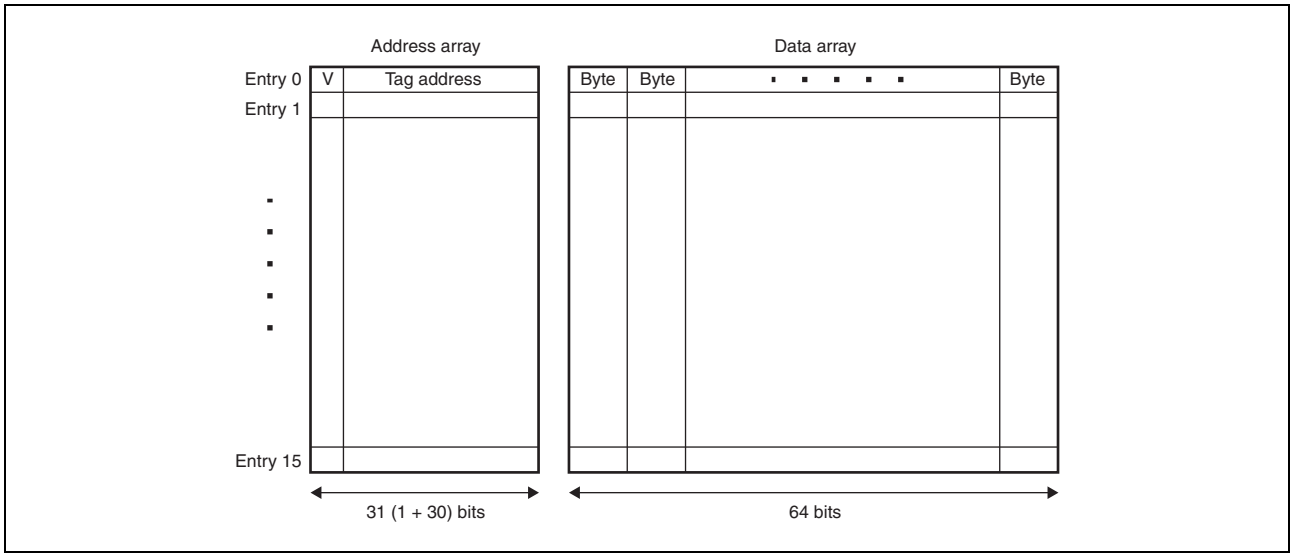

Figure 17.13 Read Cache Configuration

(1) Address Array

The V bit indicates whether the entry data is valid. When the V bit is 1, the data is valid and when V bit is 0, the data is invalid.
The tag address bits hold the address used for the serial flash memory. Address bits 32 to 3 are used for the purpose.
Address bits 23 to 3 are enabled when address output is 24 bits and one serial flash memory is connected; and address bits 24 to 3 are enabled when two serial flash memories are connected.
Address bits 31 to 3 are enabled when address output is 32 bits and one serial flash memory is connected; and address bits 32 to 3 are enabled when two serial flash memories are connected.

(2) Data Array

It retains the 64-bit read data. Registration in the read cache is performed in line units.

(3) Read Operation

In case of read-hit, data is read from the read cache. In case of read-miss, after the 64 × RBURST (read burst length) data is read from the serial flash memory and the read cache is updated, the data is returned to the bus master.

(4) Data Replacement

The write pointer is used to update data. In case of read-miss, the RBURST (read burst length) portion data is replaced starting at the entry specified by the write pointer. In other words, the data is replaced in the storage order of the data.
Whether data is referred to or not will not affect the replacement order of data.

17.5.8 SPI Operating Mode

This module can carry out an arbitrary SPI operation by using the register settings.
The transfer format is determined based on the following registers.
- Common control register (CMNCR)
- SSL delay register (SSLDR)
- Bit rate setting register (SPBCR)
- SPI mode control register (SMCR)
- SPI mode command setting register (SMCMR)
- SPI mode address setting register (SMADR)
- SPI mode option setting register (SMOPR)
- SPI mode enable setting register (SMENR)
- SPI mode read data register (SMRDR)
- SPI mode write data register (SMWDR)
- SPI mode dummy cycle setting register (SMDMCR)
- SPI mode DDR enable register (SMDRENR)*

For the address, option data, and transfer data, either SDR or DDR transfer can be selected using the appropriate register when the SPBCLK frequency division ratio is two or larger (RZ/A1LU only).
SPI operating mode can be used for reading the status of the serial flash memory and writing to the serial flash memory. In this mode, one transfer refers to the operation from when the SPIE bit in SMCR is set to 1 to when the TEND bit is set to 1.
Note: * RZ/A1LU only

(1) Transfer Start

The transfer of data is started in the set transfer format by setting the SPIE bit in SMCR to 1. When write operation is enabled, the SPI mode write data register is transmitted to the serial flash memory. When read operation is enabled, data read from the serial flash memory is stored into the SPI mode read data register.
The SPI operation timing is shown in Figure 17.14.

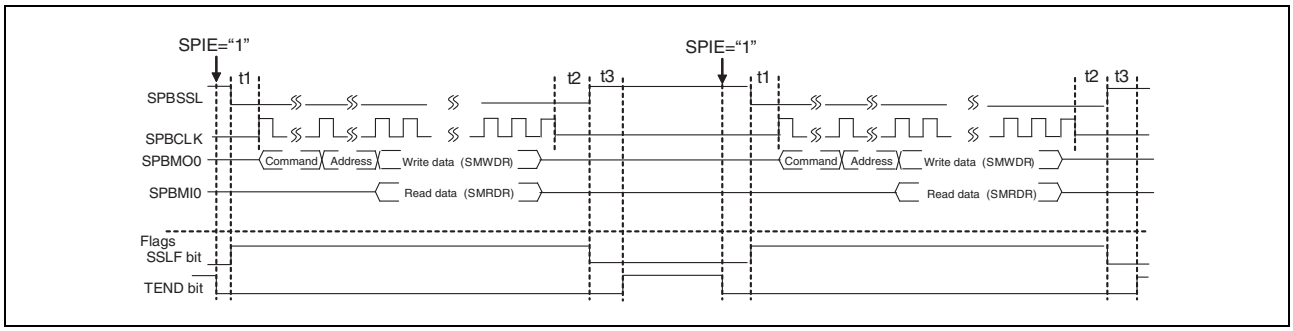

Figure 17.14 SPI Operation Timing

(2) Read/Write Enable

- Read operation: Data can be read by setting the SPIRE bit in SMCR to 1. The read data is stored into SMRDR.
- Write operation: Data can be written by setting the SPIWE bit in SMCR to 1. The data stored in SMWDR is output.

When the data size is set to 1 bit using the SPIDB[1:0] bits in SMENR, data can be transmitted and received by setting the SPIRE and SPIWE bits to 1. However, when the data size is set to 2 or 4 bits by using the SPIDB[1:0] bits, only one of the SPIRE and SPIWE bits should be enabled. The operation is not guaranteed if both the bits are enabled.

(3) Retention of SPBSSL Pin Assertion

By setting the SSLKP bit in SMCR to 1, assertion of the SPBSSL pin can be continued till the next transfer. With this function, the transfer can be carried out continuously with the SPBSSL kept in the asserted state.
The data transfer timing using the SSLKP bit is shown in Figure 17.15.

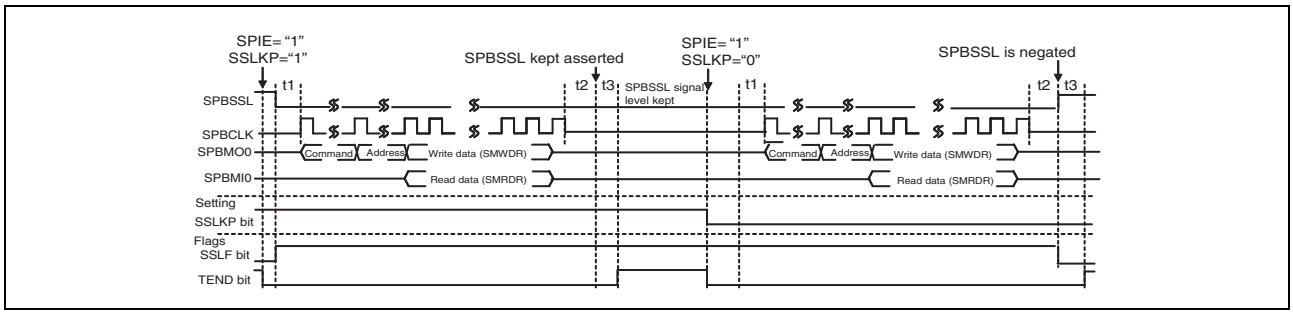

Figure 17.15 Data Transfer Timing using the SSLKP Bit

(4) Initial Setting Flow

An example of an initial setting flow in SPI operating mode is shown in Figure 17.16.

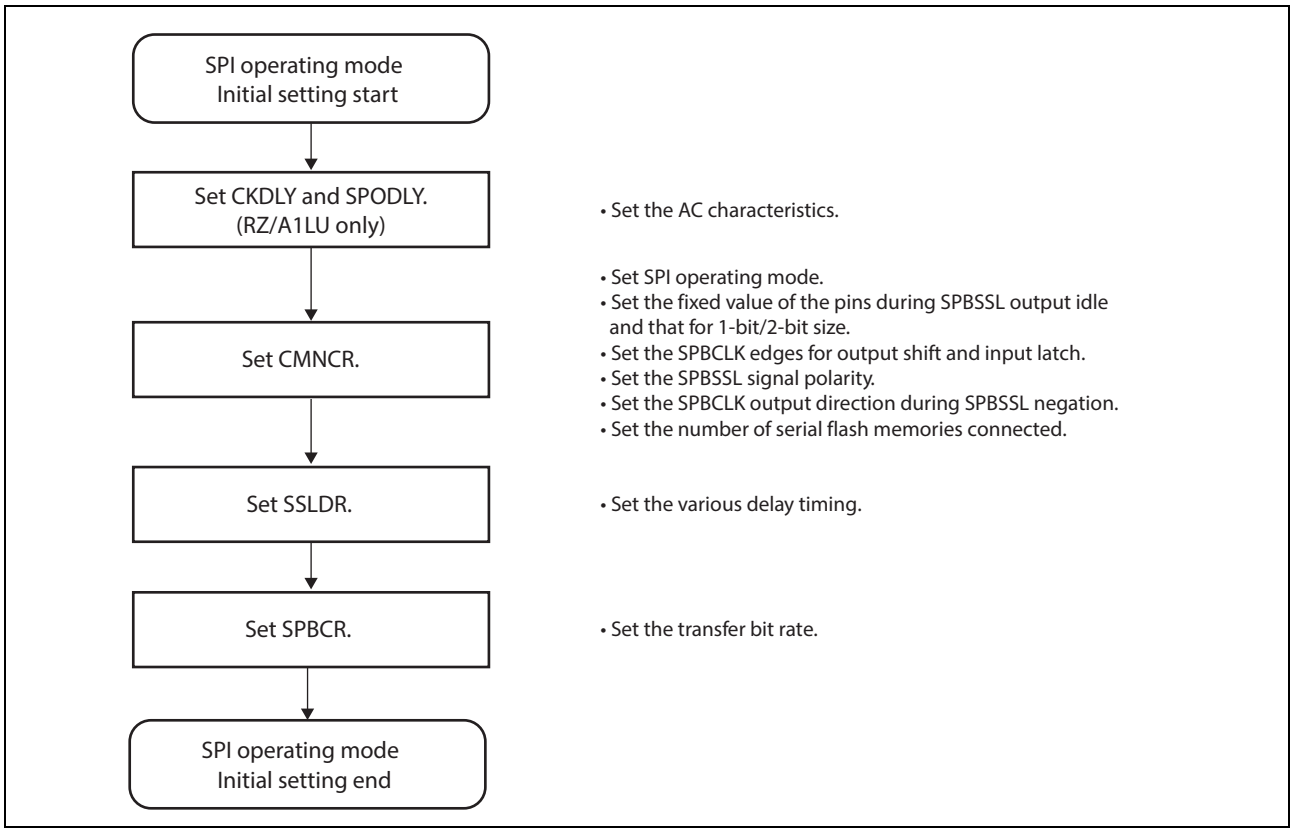

Figure 17.16 Example of Initial Setting Flow in SPI Operating Mode

(5) Data Transfer Setting Flow

An example of a data transfer setting flow in SPI operating mode is shown in Figure 17.17.

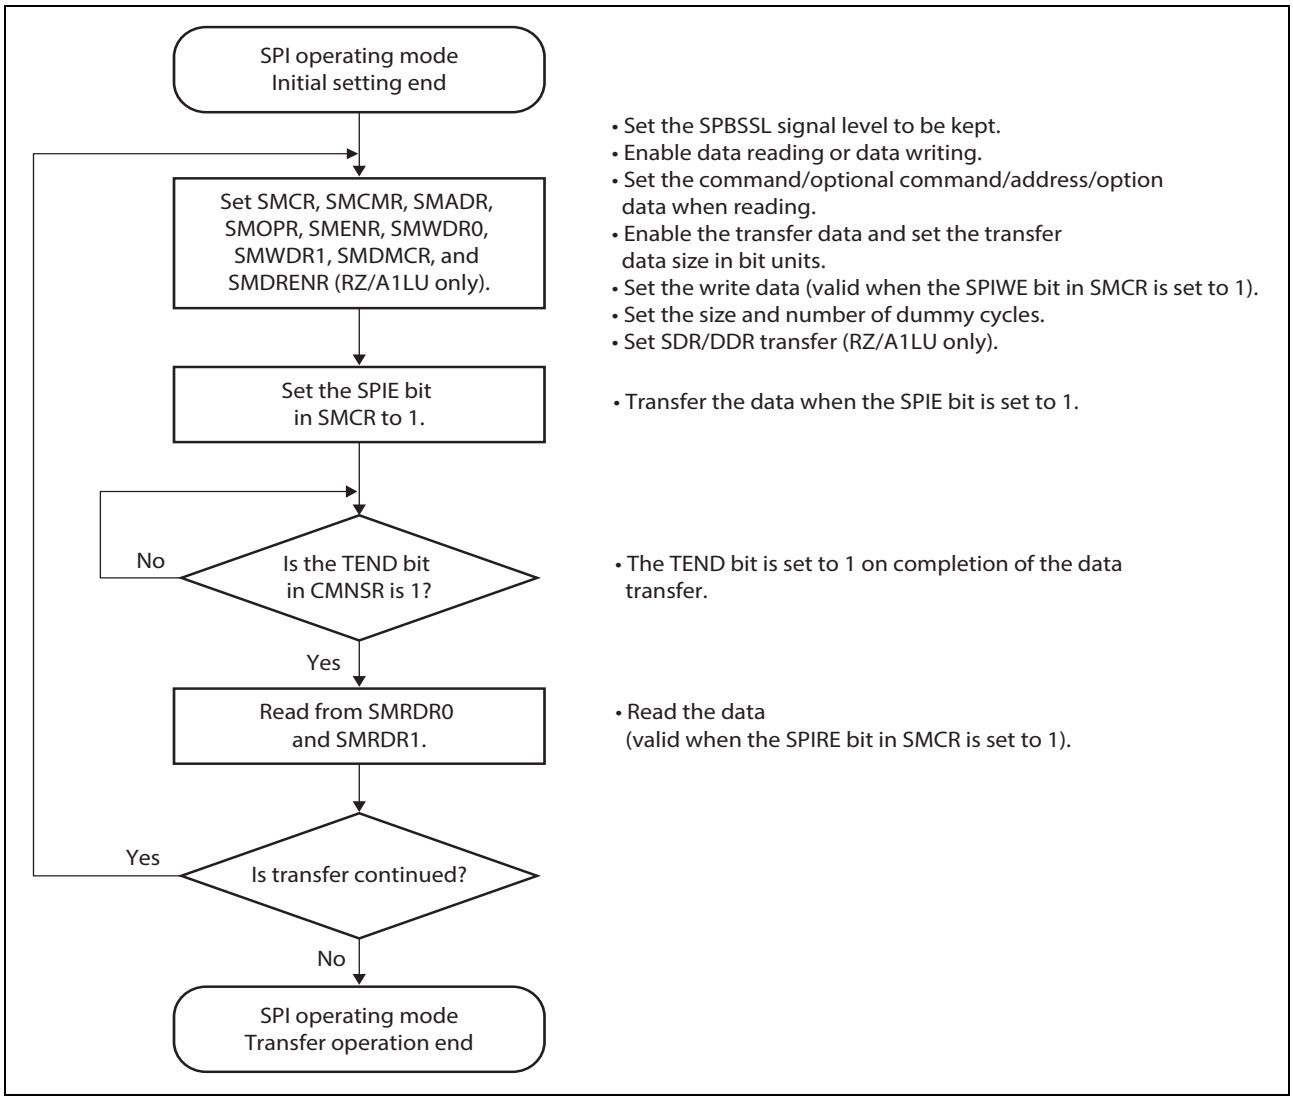

Figure 17.17 Example of a Data Transfer Setting Flow in SPI Operating Mode

17.5.9 Transfer Format

(1) SPBSSL Pin Enable Polarity Control

The enable polarity of the SPBSSL pin can be changed with the SSLP bit in CMNCR.

(2) SPBCLK Output

The SPBCLK output direction during SPBSSL negation can be set with the CPOL bit in CMNCR.

(3) Data Transmission and Reception Timing

Data transmission and reception timing is different between SDR transfer and DDR transfer (RZ/A1LU only).
During SDR transfer, data is transmitted and received at either the odd or even edges. The data transmission timing can be set to the odd or even edge with the CPHAT bit in CMNCR. Similarly, the data reception timing can be set to the odd or even edge with the CPHAR bit in CMNCR.
During DDR transfer (RZ/A1LU only), data is transmitted and received at both the odd and even edges. The first data transmission timing can be set to the odd or even edge with the CPHAT bit in CMNCR. Similarly, the first data reception timing can be set to the odd or even edge with the CPHAR bit in CMNCR.

(4) Delay Settings

t1 is the time period from SPBSSL pin assertion to SPBCLK oscillation (clock delay). It can be set with the SCKDL[2:0] bits in SSLDR. t2 is the time period till the SPBSSL signal negation after the SPBCLK oscillation is stopped (SPBSSL negation delay). It can be set with the SLNDL[2:0] bits in SSLDR. t3 is the time period required to prevent SPBSSL signal assertion for the next transfer after the end of the previous transfer (next access delay). It can be set with the SPNDL[2:0] bits in SSLDR.

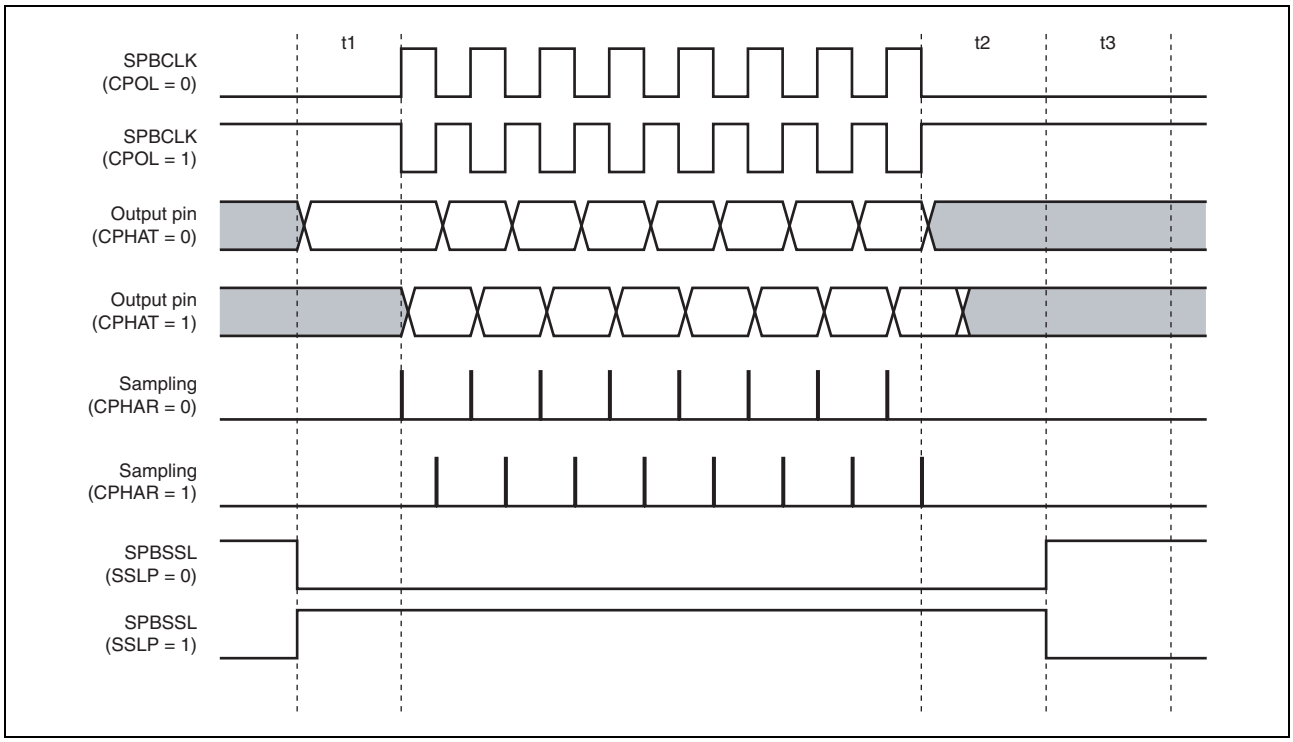

Figure 17.18 SDR Transfer Format

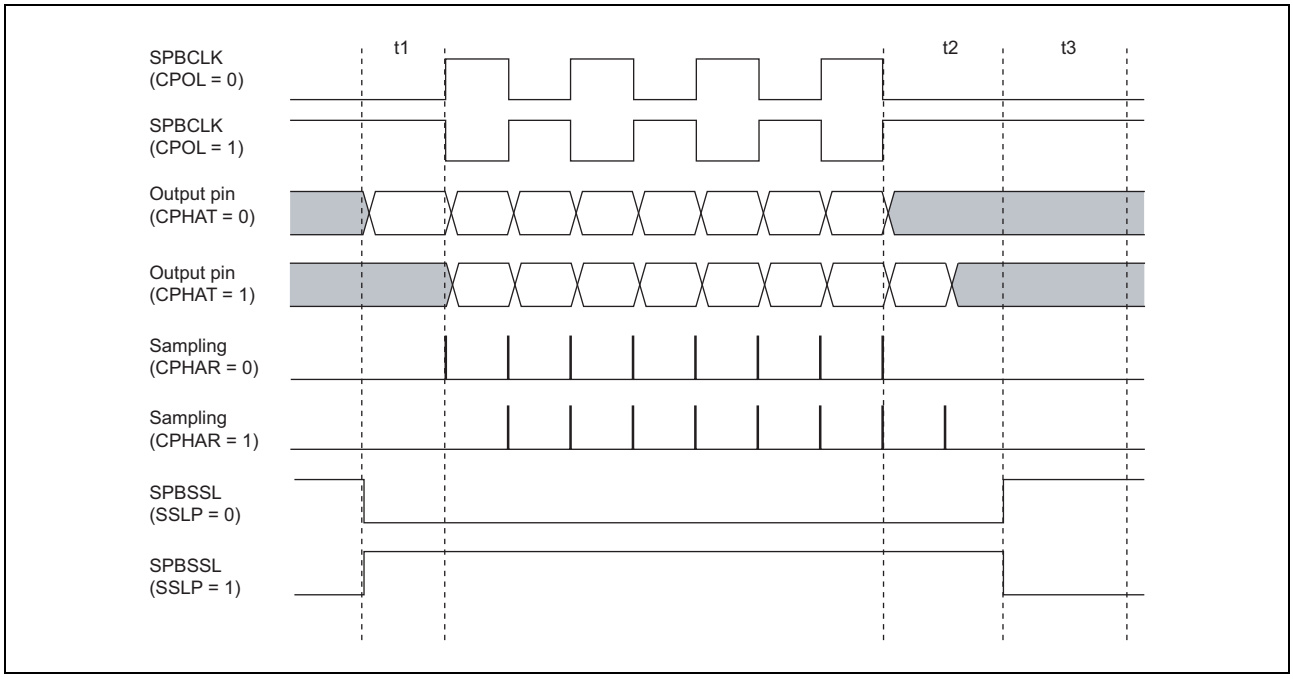

Figure 17.19 DDR Transfer Format (RZ/A1LU only)

Note: In DDR reception when CPHAR = 1, the sampling timing of the last bit is based on the frequency-divided clock in this module. When CPHAT = 1 in DDR transfer, the serial flash memory cannot provide the sampling timing of the last bit; therefore, a transfer ending with a DDR transfer is not performed correctly when CPHAT = 1.

17.5.10 Data Format

This module can input and output data in the order of command, optional command, address, option data, dummy cycle, and data.

(1) Data Registers

Table 17.5 shows the input and output data.

Table 17.5 Data Registers

Data		External Address Space Read Operation	SPI Operation
Command (8 bits)		CMD[7:0] bits in DRCMR	CMD[7:0] bits in SMCMR
Optional command (8 bits)		OCMD[7:0] bits in DRCMR	OCMD[7:0] bits in SMCMR
Address (32/24 bits)	BSZ[1:0] = 00 (one flash memory connected)	32 bits: DREAR.EAV[6:1 to 0] bits + lower [25 to 24:0] bits of the read address. 24 bits: Lower [23:0] bits of the read address	32 bits: ADR[31:0] bits in SMADR 24 bits: ADR[23:0] bits in SMADR
	BSZ[1:0] = 01 (two flash memories connected)	32 bits: DREAR.EAV[7:1 to 0] bits + lower [25 to 24:1] bits of the read address. 24 bits: Lower [24:1] bits of the read address	
Option data (8 bits × 4)		DROPR	SMOPR
Dummy cycle (1 to 8 cycles)		DRDMCR	SMDMCR (only when read)
Transfer data		Normal read: 8, 16, and 32 bits Burst read: 64 × RBURST bits	Read: SMRDR0, SMRDR1 Write: SMWDR0, SMWDR1

(2) Data Enable

In external address space read mode, transfer enable or disable of the command, optional command, address, option data, and dummy cycle can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENR, respectively. The size and number of dummy cycles can be controlled with the data read dummy cycle setting register (DRDMCR).

When the SPBCLK frequency division ratio is two or larger, either SDR or DDR transfer can be selected for the address, option data, and read data, using the ADDRE, OPDRE, and DRDRE bits in the data read DDR enable register (DRDRENR) (RZ/A1LU only).

Similarly, in SPI operating mode, enable or disable of the command, optional command, address, option data, dummy cycle, and transfer data can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], DME, and SPIDE[3:0] bits in SMENR, respectively. However, disabling all the above parameters is prohibited in SPI operating mode. At least one of them except dummy cycle must be enabled. The size and number of dummy cycles can be controlled with the SPI mode dummy cycle setting register (SMDMCR).

When the SPBCLK frequency division ratio is two or larger, either SDR or DDR transfer can be selected for the address, option data, and transfer data, using the ADDRE, OPDRE, and SPIDRE bits in the SPI mode DDR enable register (SMDRENR) (RZ/A1LU only).

For the address and option data in external address space read mode; and the address, option data, and transfer data in SPI operating mode, the enable bit setting allowed is determined according to the transfer data size. For the allowed setting combinations of the enable bits and transfer data size, refer to the description of the pertinent register.

If data is disabled, that data is skipped, and input and output of the next data is carried out. The command, optional command, address, and option data are always output. During dummy cycles, the state of the used pins is Hi-Z. In external address space read mode, data is always input; and in SPI operating mode, input and output of data is determined based on the settings of the SPIRE and SPIWE bits in SMCR.

There are some restrictions on dummy cycle insertion; refer to the description of the DME bits in DRENR and SMENR for details.

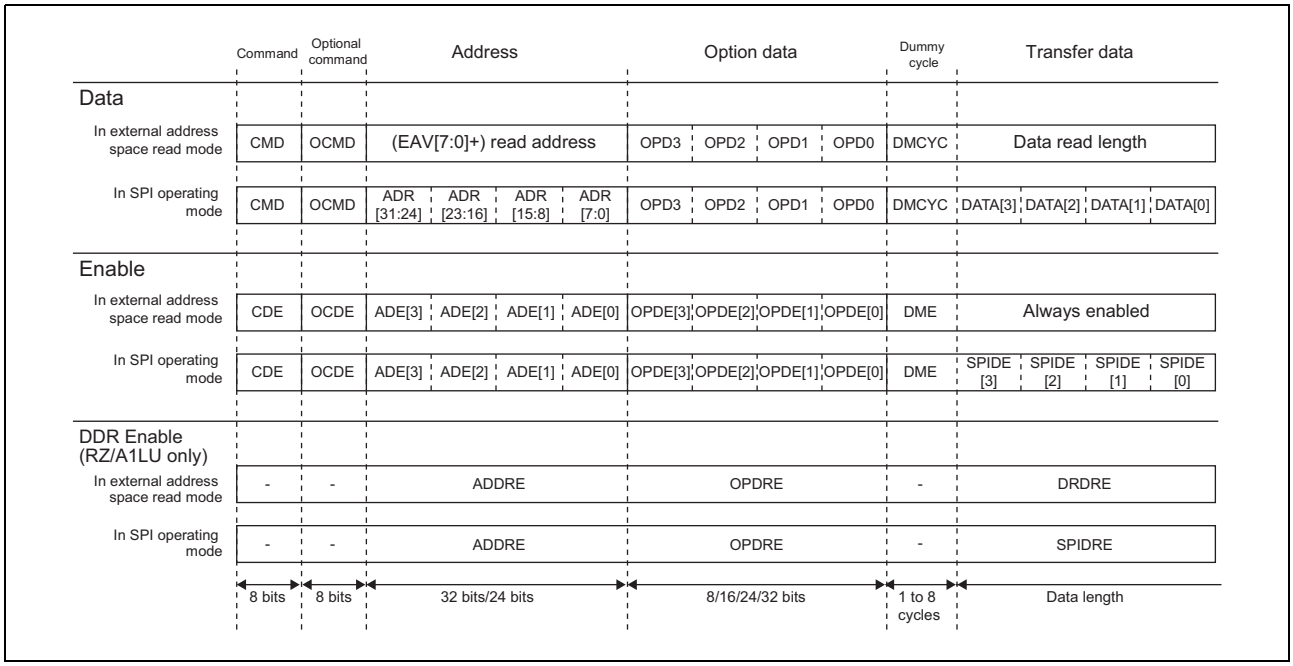

Figure 17.20 Data and Enable

(3) Bit Size

In external address space read mode, the size of the command, optional command, address, option data, and the read data in bit units is respectively controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and DRDB[1:0] bits in DRENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in DRDMCR.
Similarly, in SPI operating mode, the size of the command, optional command, address, option data, and read write data in bit units is controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and SPIDB[1:0] bits in SMENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in SMDMCR.

(a) 1-bit Size

When the size is set to 1 bit, SPBMI0 and SPBMI1 pins will be the input pins and SPBMO0 and SPBMO1 pins will be the output pins. SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins are not used.
Figure 17.21 and Figure 17.22 show the transfer format examples.

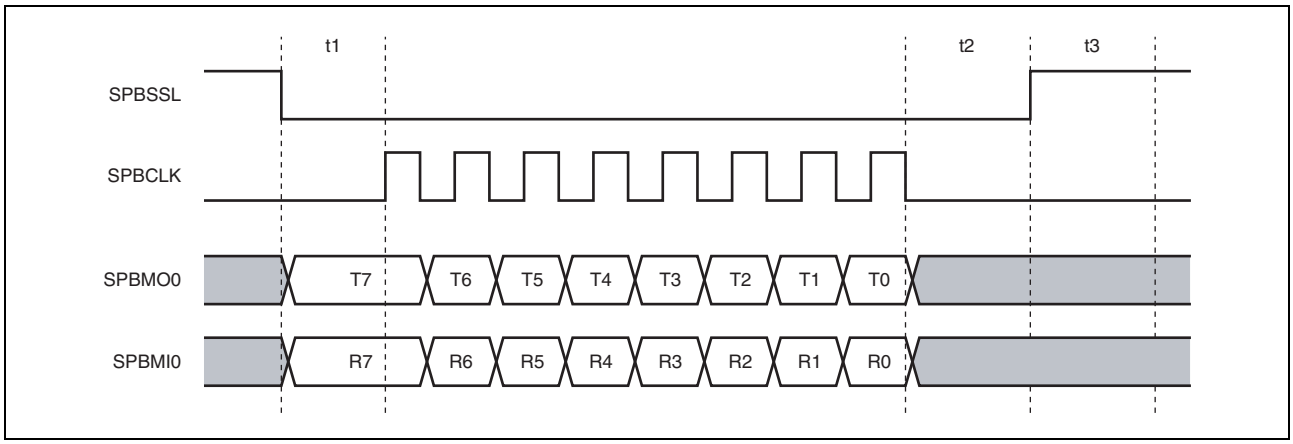

Figure 17.21 Transfer Format Example with 1-Bit Data Size and One Serial Flash Memory Connected

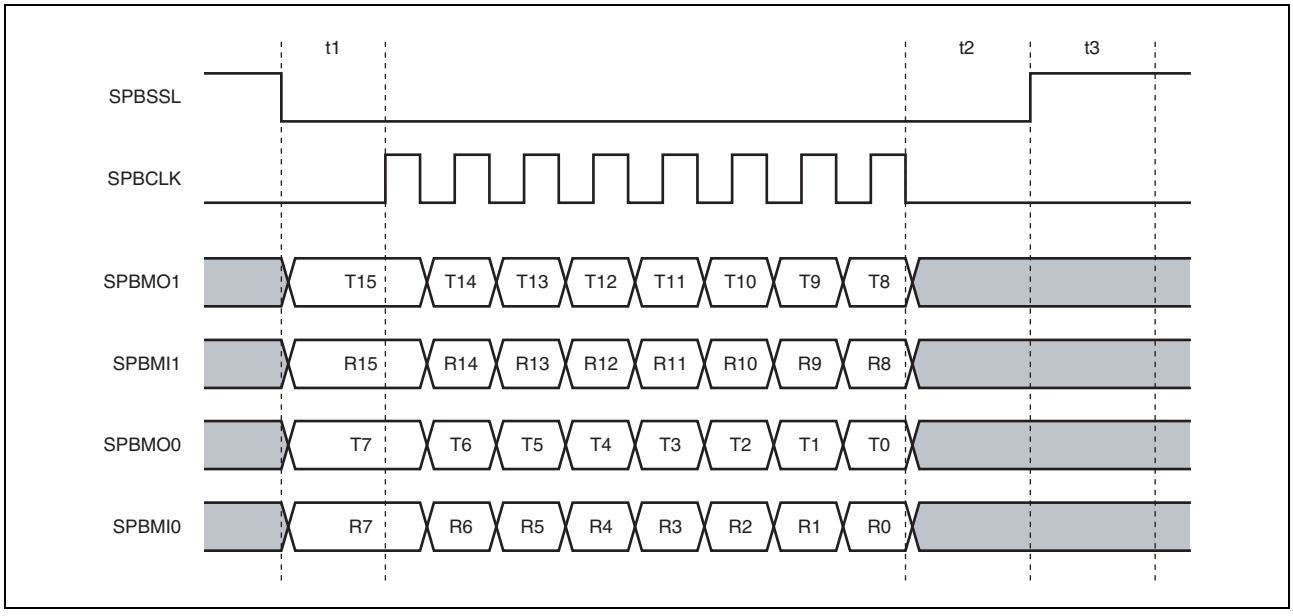

Figure 17.22 Transfer Format Example with 1-Bit Data Size and Two Serial Flash Memories Connected

(b) 2-bit Size

When the size is set to 2 bits, SPBIO0_0, SPBIO01, SPBIO10, and SPBIO11 pins will be either the input pins or the output pins. SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins are not used.
Figure 17.23 and Figure 17.24 show the transfer format examples.

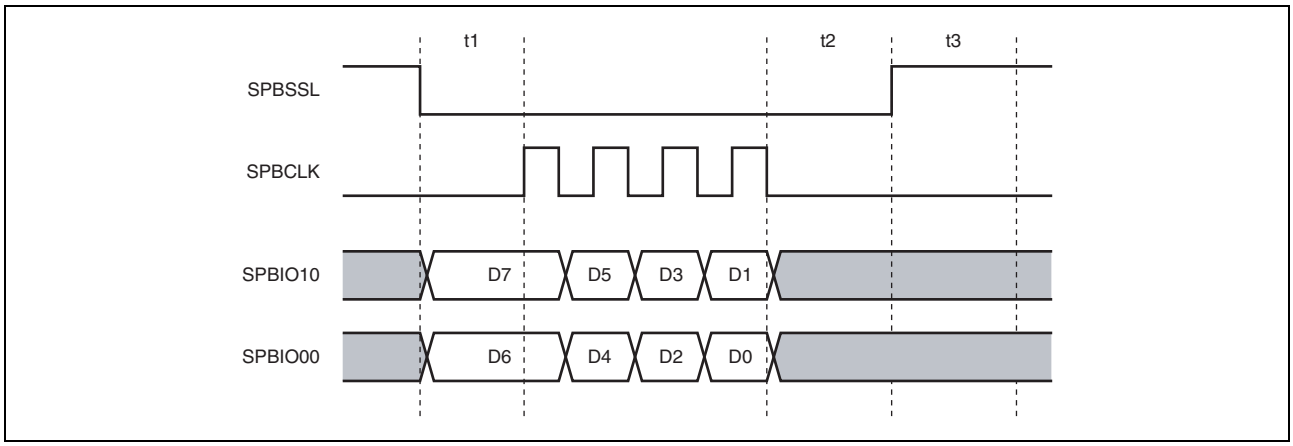

Figure 17.23 Transfer Format Example with 2-Bit Data Size and One Serial Flash Memory Connected

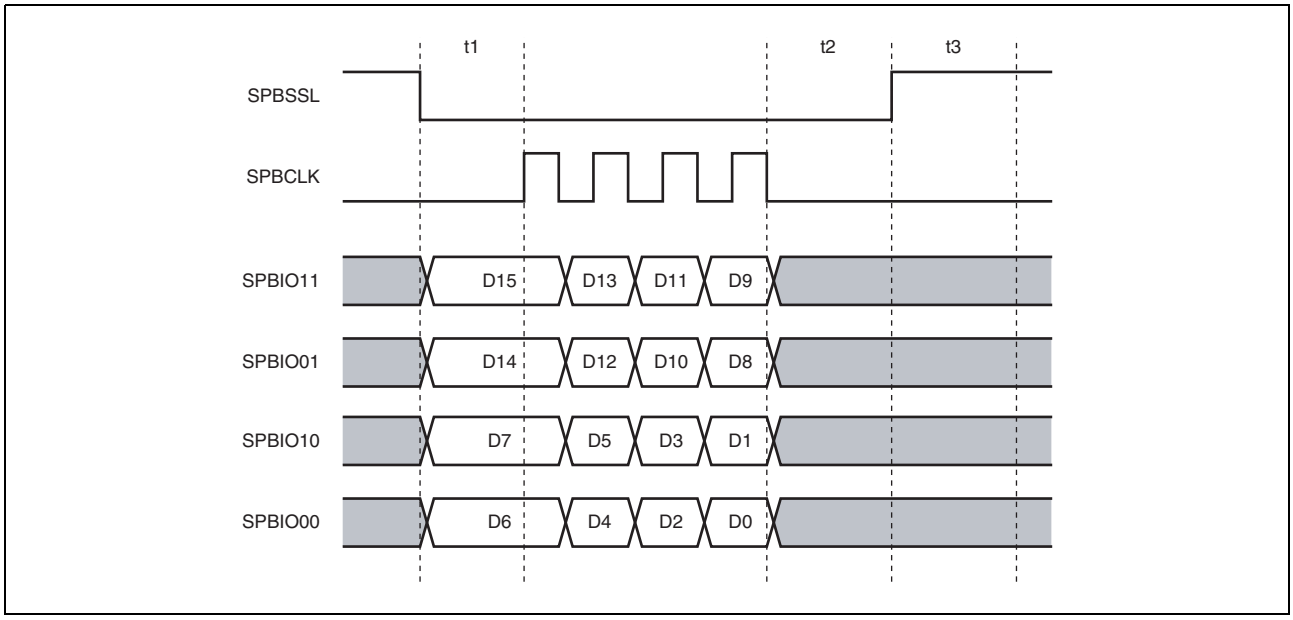

Figure 17.24 Transfer Format Example with 2-Bit Data Size and Two Serial Flash Memories Connected

(c) 4-bit Size

When the size is set to 4 bits, SPBIO00, SPBIO01, SPBIO10, SPBIO11, SPBIO20, SPBIO21, SPBIO30, and SPBIO31 pins will be either the input pins or the output pins.
Figure 17.25 and Figure 17.26 show the transfer format examples.

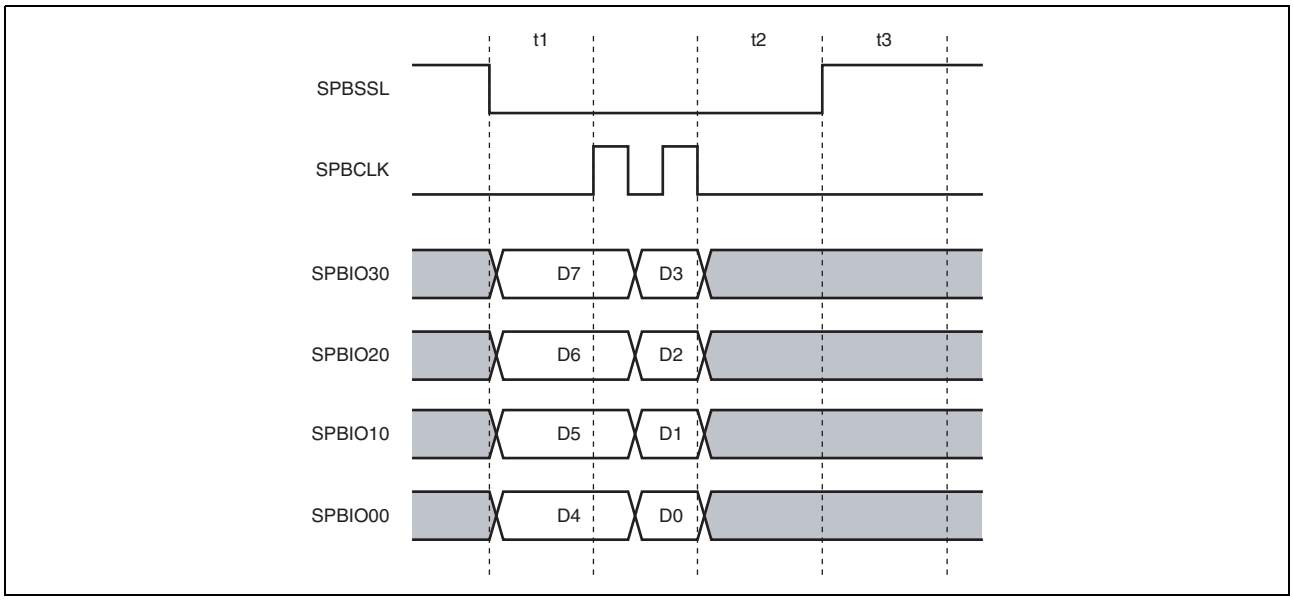

Figure 17.25 Transfer Format Example with 4-Bit Data Size and One Serial Flash Memory Connected

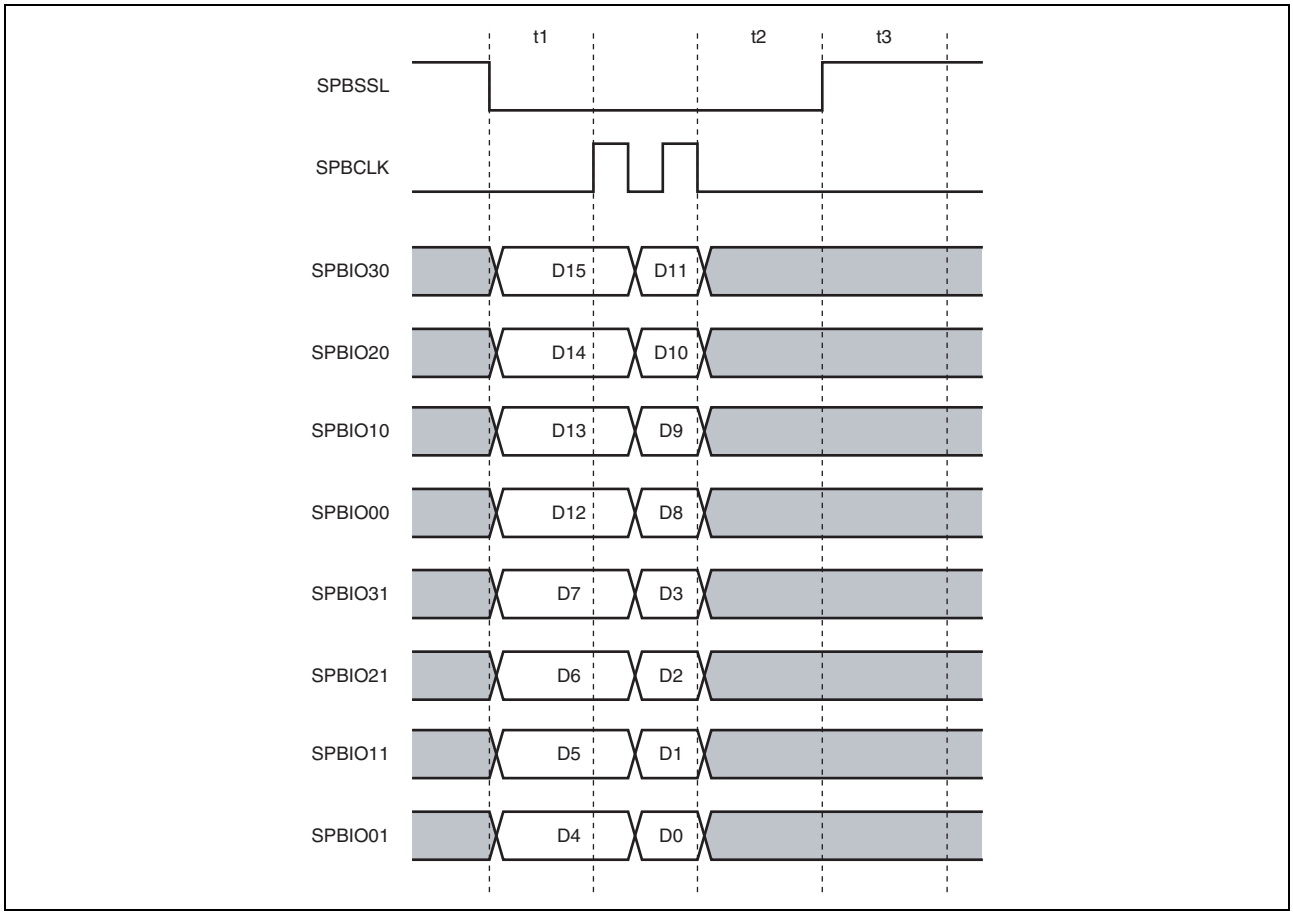

Figure 17.26 Transfer Format Example with 4-Bit Data Size and Two Serial Flash Memories Connected

17.5.11 Data Pin Control

With this module, the status of pins can be automatically changed based on the data size to be used and the read/write settings. The pin status during the SPBSSL negation can be set with the MOIIO3, MOIIO2, MOIIO1, and MOIIO0 bits in CMNCR. The SPBSSL and SPBCLK pins are always output pins. The status of respective pins is specified in Table 17.6 to Table 17.9.

Table 17.6 Pin Status (1)

		SPBSSL Assertion		
		Command, Optional Command, Address, Option Data		
Pin	**SPBSSL Negation**	**1-bit Size**	**2-bit Size**	**4-bit Size**
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	MOIIO0 bit value	Output	Output	Output
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	MOIIO1 bit value	Hi-Z	Output	Output
SPBIO20, SPBIO21	MOIIO2 bit value	IO2FV bit value	IO2FV bit value	Output
SPBIO30, SPBIO31	MOIIO3 bit value	IO3FV bit value	IO3FV bit value	Output

Table 17.7 Pin Status (2)

	Transfer Data					
	External Address Space Read Operation			SPI Operation		
				SPIRE Bit = 1, SPIWE Bit = 0		
Pin	**1-bit Size**	**2-bit Size**	**4-bit Size**	**1-bit Size**	**2-bit Size**	**4-bit Size**
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	IO0FV bit value	Input	Input	IO0FV bit value	Input	Input
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	Input	Input	Input	Input	Input	Input
SPBIO20, SPBIO21	IO2FV bit value	IO2FV bit value	Input	IO2FV bit value	IO2FV bit value	Input
SPBIO30, SPBIO31	IO3FV bit value	IO3FV bit value	Input	IO3FV bit value	IO3FV bit value	Input

Table 17.8 Pin Status (3)

	Transfer Data

SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	Hi-Z	Output	Output	Input	Setting prohibited	Setting prohibited
SPBIO20, SPBIO21	IO2FV bit value	IO2FV bit value	Output	IO2FV bit value	Setting prohibited	Setting prohibited
SPBIO30, SPBIO31	IO3FV bit value	IO3FV bit value	Output	IO3FV bit value	Setting prohibited	Setting prohibited

Table 17.9 Pin Status (4)

	Dummy Cycle		
Pin	**1-bit Size**	**2-bit Size**	**4-bit Size**
SPBMO0/ SPBIO00, SPBMO1/ SPBIO01	IO0FV bit value	Hi-Z	Hi-Z
SPBMI0/ SPBIO10, SPBMI1/ SPBIO11	Hi-Z	Hi-Z	Hi-Z
SPBIO20, SPBIO21	IO2FV bit value	IO2FV bit value	Hi-Z
SPBIO30, SPBIO31	IO3FV bit value	IO3FV bit value	Hi-Z

17.5.12 SPBSSL Pin Control

Negation conditions of the SPBSSL pin are as follows.

(1) External Address Space Read Mode

(a) Normal read operation (RBE bit in DRCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(b) Burst read without automatic SPBSSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(c) Burst read with automatic SPBSSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 1)

- SPBSSL negated after t2 cycle when the read address is not continuous with the previously read address
- SPBSSL negated after the SSLN bit in DRCR is set to 1

(2) SPI Operating Mode

(a) SPBSSL pin assertion not retained (SSLKP bit in SMCR = 0)

SPBSSL negated after completing the data transfer and t2 cycle.

(b) SPBSSL pin assertion retained (SSLKP bit in SMCR = 1)

SPBSSL not negated.
When to be negated, data should be transferred after setting the SSLKP bit to 0.

17.5.13 Flags

This module has two flag bits SSLF and TEND in CMNSR. These bits are read-only bits.

(1) SSLF Bit

This bit indicates the SPBSSL pin status. The status is 1 when the SPBSSL is asserted, and the status is 0 when the SPBSSL is negated.

(2) TEND Bit

This bit indicates whether transfer of data is in progress or the transfer of data has ended.
During t1 time period, data transfer, t2 time period, t3 time period, and waiting for read access by burst read and SPBSSL automatic negation, the TEND bit is read as 0 to indicate that the transfer of data is in progress.
When other than the above, the TEND bit is read as 1 to indicate that transfer of data has ended.

(3) Register Re-writing Timing

The status of the TEND bit determines the rewritable registers.
The registers which can be written to, except the SSLN bit in DRCR, should be modified when TEND = 1. Read SMRDR0 and SMRDR1 when TEND = 1. CMNSR can always be read.

17.6 Usage Notes

17.6.1 Notes on Transfer to Read Data in SPI Operating Mode

If the setting for the bit mode is for division by two or more in SPI operating mode, take note of the following points for caution when setting the SPI mode enable setting register (SMENR) to enable transfer only for reading data.
“Transfer only for reading data” indicates transfer to read data while the CDE, OCDE, ADE[3:0], and OPDE[3:0] bits in SMENR are all 0.

(1) Transfer to read data while the signal on the SPBSSL pin is de-asserted

Set the SMENR.SPIDE[3:0] bits to 1100 or 1111 when transfer only for reading data is to proceed.
Transfer will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000.

(2) Transfer to read data while the signal on the SPBSSL pin is asserted

When transfer only for reading data is to proceed, set the SMENR.SPIDE[3:0] bits to 1100 or 1111, or end the immediately preceding transfer with reading data.
When the immediately preceding transfer is of a command, optional command, address, or option data, or is transfer for writing data, the subsequent transfer only for reading data will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000.

17.6.2 Notes on Starting Transfer from the SPBSSL Retained State in SPI Operating Mode

Be sure to set the SPIWE bit in the SMCR register to 1 when the transfer of a command, optional command, address, or option data is started while the SPBSSL pin is being asserted in SPI operating mode.

18. I2C Bus Interface

This section gives an overall description of the I2C bus interface (RIIC).

The first section describes the features specific to this LSI, including the number of channels and the register base addresses. The subsequent sections describe the RIIC's functions and registers.

18.1 Features

18.1.1 Channels

This LSI has the following number of channels of the I2C bus interface (RIIC).

Table 18.1 Channels of RIIC

Product Name	RZ/A1L 176 pins	RZ/A1L 208 pins
Number of channels	4	
Name	RIICn (n = 0 to 3)	

Table 18.2 Index

Index	Description
n	Throughout this section, each channel of the I2C bus interface is identified by the index "n" (n = 0 to 3). For example, RIICnCR1 is I2C bus control register 1.

18.1.2 Register Base Addresses

The base address <RIICn_base> of each RIICn is listed in the following table.

All RIICn register addresses are given as values obtained by adding offsets to the register base address <RIICn_base> for each channel.

Table 18.3 Register Base Address

Channel	Base Address Name	Base Address
RIIC0	<RIIC0_base>	FCFE E000H
RIIC1	<RIIC1_base>	FCFE E400H
RIIC2	<RIIC2_base>	FCFE E800H
RIIC3	<RIIC3_base>	FCFE EC00H

18.1.3 External I/O Signals

The following table shows the external I/O signals of the RIICn.

Table 18.4 RIICn Pin Configuration

Channel	Multiplexed Pin Name	Function
RIIC0	RIIC0SCL	RIIC0 serial clock I/O pin
	RIIC0SDA	RIIC0 serial data I/O pin
RIIC1	RIIC1SCL	RIIC1 serial clock I/O pin
	RIIC1SDA	RIIC1 serial data I/O pin
RIIC2	RIIC2SCL	RIIC2 serial clock I/O pin
	RIIC2SDA	RIIC2 serial data I/O pin
RIIC3	RIIC3SCL	RIIC3 serial clock I/O pin
	RIIC3SDA	RIIC3 serial data I/O pin

18.2 Overview

18.2.1 Functional Overview

Communications format

- I2C bus format or SMBus format
- Master mode or slave mode selectable
- Automatic securing of the various set-up times, hold times, and bus-free times for the transfer rate

Transfer rate

Up to 400 kbps

SCL clock

For master operation, the duty cycle of the SCL clock is selectable in the range from 0% to 100%.

Issuing and detecting conditions

- Start, restart, and stop conditions are automatically generated.
- Start conditions (including restart conditions) and stop conditions are detected.

Slave address

- Up to three slave-address settings can be made.
- Seven- and ten-bit address formats are supported (along with the use of both at once).
- General call addresses, device ID addresses, and SMBus host addresses are detectable.

Acknowledgement

- For transmission, the acknowledge bit is automatically loaded
  - Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit.
- For reception, the acknowledge bit is automatically transmitted
  - If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.

Wait function

- In reception, the following periods of waiting can be obtained by holding the clock signal (SCL) at the low level:
  - Waiting between the eighth and ninth clock cycles
  - Waiting between the ninth clock cycle and the first clock cycle of the next transfer (WAIT function)

SDA output delay function

Timing of the output of transmitted data, including the acknowledge bit, can be delayed.

Arbitration

- For multi-master operation
  - Operation to synchronize the SCL (clock) signal in cases of conflict with the SCL signal from another master is possible.
  - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line.
  - In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line.
- Loss of arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the issuing of double start conditions).
- Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching is detectable.
- Loss of arbitration due to non-matching of internal and line levels for data is detectable in slave transmission.

Timeout function

The internal time-out function is capable of detecting long-interval stop of the SCL (clock signal).

Noise removal

The interface incorporates analog noise filters and digital noise filters for input on the RIICnSCL and RIICnSDA pins, and the width for noise cancellation by the digital noise filters is adjustable by software.

Interrupt sources

- Eight sources:
  - Transmission complete
  - Receive data full
  - Transmit data empty
  - Detection of a stop condition
  - Detection of a start condition
  - Reception of a NACK
  - Arbitration lost
  - Timeout

Low power consumption function

Module-stop state can be set.

18.2.2 Block Diagram

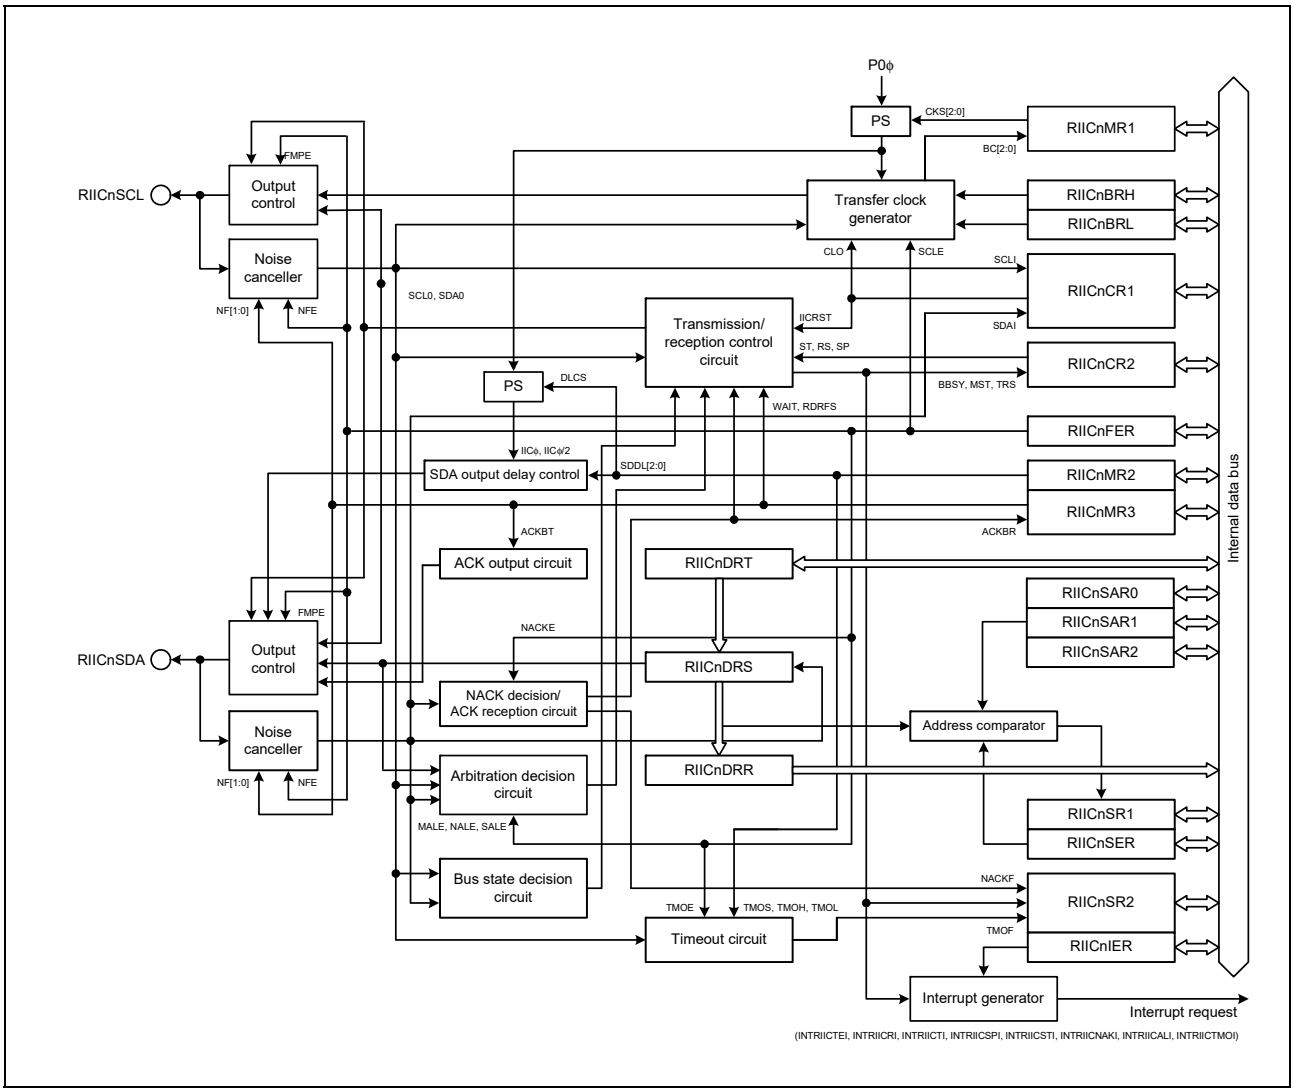

Figure 18.1 Block Diagram of RIIC

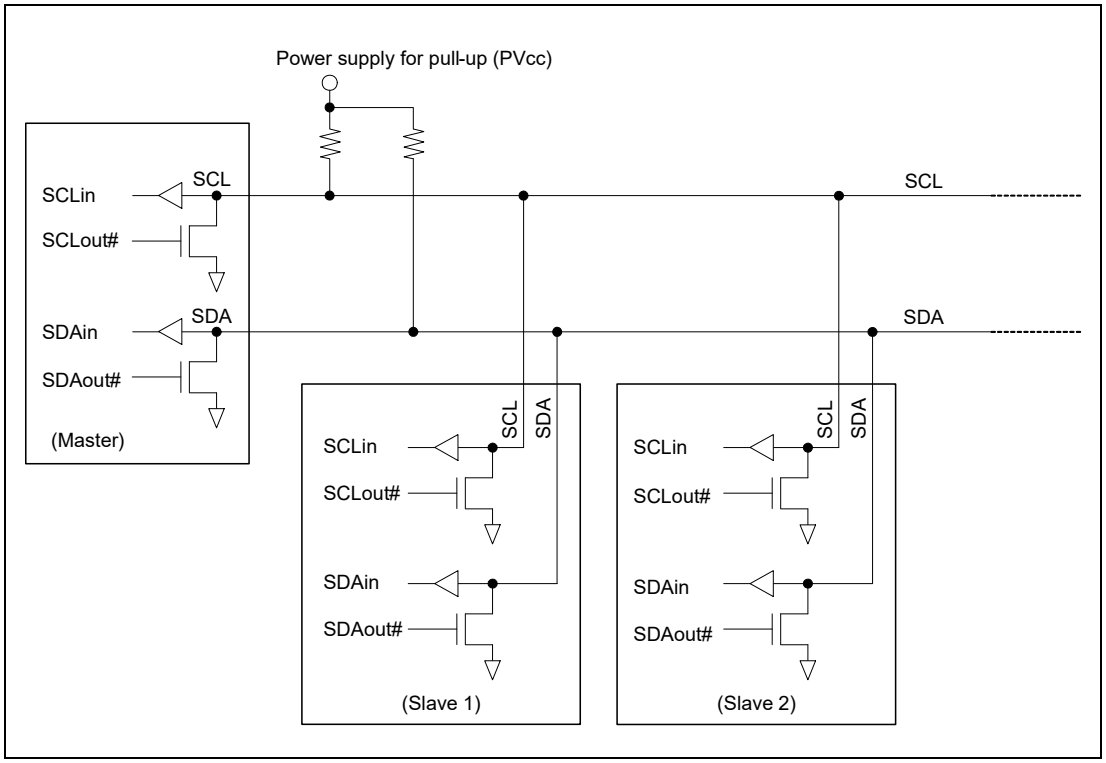

Figure 18.2 Connections to the External Circuit by the I/O Pins (I2C Bus Configuration Example)

RIICnSCL and RIICnSDA are Schmitt input/open-drain output pins for both master and slave operations. Because the output is open drain, an external pull-up resistor is required.

18.3 Registers

18.3.1 RIICnCR1 — I2C Bus Control Register 1

Access: RIICnCR1 is a 32-bit readable/writable register.
RIICnCR1L and RIICnCR1H are 16-bit readable/writable registers.
RIICnCR1LL, RIICnCR1LH, RIICnCR1HL, and RIICnCR1HH are 8-bit readable/writable registers.

Address: RIICnCR1: <RIICn_base> + 0000_H
RIICnCR1L: <RIICn_base> + 0000_H, RIICnCR1H: <RIICn_base> + 0002_H
RIICnCR1LL: <RIICn_base> + 0000_H, RIICnCR1LH: <RIICn_base> + 0001_H, RIICnCR1HL: <RIICn_base> + 0002_H,
RIICnCR1HH: <RIICn_base> + 0003_H

Initial Value: 0000 $001F_H$. This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Initial value	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 18.5 RIICnCR1 register contents (1/2)

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	ICE	I2C Bus Interface Enable 0: Output from the RIICnSCL and RIICnSDA pins is disabled (and input to the RIICnSCL and RIICnSDA pins is enabled). 1: Enabled (RIICnSCL and RIICnSDA pins driven) (This bit can select the RIIC reset or internal reset in combination with the IICRST bit.)
6	IICRST	I2C Bus Interface Internal Reset 0: Clears the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL/SDA output latch)
5	CLO	Extra SCL Clock Cycle Output 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.)
4	SOWP*2	SCLO/SDAO Write Protect 0: Allows the SCLO and SDAO bits to be rewritten. (This bit is read as 1.)
3	SCLO*1,*2	SCL Output Control • Read: 0: RIICnSCL pin output is at a low level. 1: RIICnSCL pin is in a high-impedance state. • Write: 0: Changes the RIICnSCL pin output to a low level. 1: Changes the RIICnSCL pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.)

Table 18.5 RIICnCR1 register contents (2/2)

Bit Position	Bit Name	Function
2	SDAO[*1,*2]	SDA Output Control • Read: 0: RIICnSDA pin output is at a low level. 1: RIICnSDA pin is in a high-impedance state. • Write: 0: Changes the RIICnSDA pin output to a low level. 1: Changes the RIICnSDA pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.)
1	SCLI	SCL Bus Input Monitor 0: RIICnSCL pin input is at a low level. 1: RIICnSCL pin input is at a high level.
0	SDAI	SDA Bus Input Monitor 0: RIICnSDA pin input is at a low level. 1: RIICnSDA pin input is at a high level.

Note 1. Do not write to these bits during communication. Changing a value during communication may cause a transmission or reception failure or an AL error.

Note 2. To change the SDAO and SCLO bits, set the SOWP bit to 0 at the same timing to set the SDAO and SCLO bits to 0.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see Section 18.13.2, Extra SCL Clock Cycle Output Function.

IICRST Bit (I2C Bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.

Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 18.6 lists the resets of the RIIC.

The RIIC reset resets all registers including the RIICnCR2.BBSY flag (except ICE and IICRST) and internal states of the RIIC, and the internal reset resets the bit counter (RIICnMR1.BC[2:0] bits), the I2C bus shift register (RIICnDRS), and the I2C bus status registers (RIICnSR1 and RIICnSR2) as well as the internal states of the RIIC. For the reset conditions for each register, see Section 18.15, Reset Function of RIIC.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the RIICnSCL pin and RIICnSDA pin at a high impedance.

CAUTION

If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCL line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 18.6 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers (except ICE and IICRST) and internal states of the RIIC.
	1	Internal reset	Reset the RIICnMR1.BC[2:0] bits, and the RIICnSR1, RIICnSR2, RIICnDRS registers and the internal states of the RIIC.

ICE Bit (I2C Bus Interface Enable)

The ICE bit selects driving or non-driving of the RIICnSCL and RIICnSDA pins. Moreover, this bit can perform two types of reset in combination with the IICRST bit. For the types of reset, see Table 18.6, RIIC Resets.

Set the ICE bit to 1 when using RIIC. Setting the ICE bit to 1 selects driving of the RIICnSCL and RIICnSDA pins.

Set the ICE bit to 0 when RIIC is not to be used. Clearing the ICE bit to 0 disables output from the RIICnSCL and RIICnSDA pins.

18.3.2 RIICnCR2 — I2C Bus Control Register 2

Access: RIICnCR2 is a 32-bit readable/writable register.
RIICnCR2L and RIICnCR2H are 16-bit readable/writable registers.
RIICnCR2LL, RIICnCR2LH, RIICnCR2HL, and RIICnCR2HH are 8-bit readable/writable registers.

Address: RIICnCR2: <RIICn_base> + 0004_H
RIICnCR2L: <RIICn_base> + 0004_H, RIICnCR2H: <RIICn_base> + 0006_H
RIICnCR2LL: <RIICn_base> + 0004_H, RIICnCR2LH: <RIICn_base> + 0005_H, RIICnCR2HL: <RIICn_base> + 0006_H, RIICnCR2HH: <RIICn_base> + 0007_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 18.7 RIICnCR2 register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	BBSY	Bus Busy Detection Flag 0: The I2C bus is released (bus free state). 1: The I2C bus is occupied (bus busy state or in the bus free state).
6	MST	Master/Slave Mode 0: Slave mode 1: Transmit mode
5	TRS	Transmit/Receive Mode 0: Receive mode 1: Transmit mode
4	—	Reserved This bit is read as 0. The write value should be 0.
3	SP	Stop Condition Issuance Request 0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.
2	RS	Restart Condition Issuance Request 0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.
1	ST	Start Condition Issuance Request 0: Does not request to issue a start condition. 1: Requests to issue a start condition.
0	—	Reserved This bit is read as 0. The write value should be 0.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free).

For details on the start condition issuance, see Section 18.12, Start Condition/Restart Condition/ Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free).
Note that arbitration may be lost if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.

When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the restart condition issuance, see Section 18.12, Start Condition/Restart Condition/ Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the RS bit with the RIICnCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued or a start condition is detected
- When a stop condition is detected
- When the RIICnCR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Do not set the RS bit to 1 while issuing a stop condition.
2. It is commended to issue a restart condition in master transmit mode. If the RS bit is set to 1 (restart condition issuance request) in mode other than master mode, the restart condition is not issued in this mode but the restart condition issuance request bit remains set. If the operating mode changes to master mode with the bit not being cleared, the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.

When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the stop condition issuance, see Section 18.12, Start Condition/Restart Condition/ Stop Condition Issuing Function.

[Setting condition]

When 1 is written to the SP bit with both the RIICnCR2.BBSY flag and the RIICnCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued or a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Wring to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free).
2. Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to the value for transmission mode or reception mode by detection or issuing of a start condition, setting or clearing of the R/W# bit, etc.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in RIICnSER, with the R/W# bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The RIICnSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in RIICnSER when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave transmit mode, a restart condition is detected (a restart condition is detected with

RIICnCR2.BBSY = 1 and RIICnCR2.MST = 0)

- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to the value for master mode or slave mode by detection or issuing of a start condition, etc.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)

[Clearing conditions]

- When a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection)

The BBSY flag indicates whether the I2C bus is occupied (bus busy) or released (bus free).

This bit is set to 1 when the SDA line changes from high to low under the condition of SCL = high, assuming that a start condition has been issued.

When the SDA line changes from low to high under the condition of SCL = high, this bit is cleared to 0 after the bus free time (specified in RIICnBRL) start condition is not detected, assuming that a stop condition has been issued.

[Setting condition]

When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in RIICnBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the RIICnCR1.IICRST bit with the RIICnCR1.ICE bit set to 0 (RIIC reset)

18.3.3 RIICnMR1 — I2C Bus Mode Register 1

Access: RIICnMR1 is a 32-bit readable/writable register.
RIICnMR1L and RIICnMR1H are 16-bit readable/writable registers.
RIICnMR1LL, RIICnMR1LH, RIICnMR1HL, and RIICnMR1HH are 8-bit readable/writable registers.

Address: RIICnMR1: <RIICn_base> + 0008_H
RIICnMR1L: <RIICn_base> + 0008_H, RIICnMR1H: <RIICn_base> + $000A_H$
RIICnMR1LL: <RIICn_base> + 0008_H, RIICnMR1LH: <RIICn_base> + 0009_H, RIICnMR1HL: <RIICn_base> + $000A_H$,
RIICnMR1HH: <RIICn_base> + $000B_H$

Initial Value: 0000 0008_H This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3	BCWP*1	BC Write Protect 0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.)
2 to 0	BC[2:0]	Bit Counter b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits

Note 1. When rewriting the BC[2:0] bits, write 0 to the BCWP bit simultaneously.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames when the SCL line is at a low level.

The values of the BC[2:0] bits return to 000_B at the end of a data transfer including the acknowledge bit or when a start condition including a restart condition is detected.

18.3.4 RIICnMR2 — I²C Bus Mode Register 2

Access: RIICnMR2 is a 32-bit readable/writable register.
RIICnMR2L and RIICnMR2H are 16-bit readable/writable registers.
RIICnMR2LL, RIICnMR2LH, RIICnMR2HL, and RIICnMR2HH are 8-bit readable/writable registers.

Address: RIICnMR2: <RIICn_base> + $000C_H$
RIICnMR2L: <RIICn_base> + $000C_H$, RIICnMR2H: <RIICn_base> + $000E_H$
RIICnMR2LL: <RIICn_base> + $000C_H$, RIICnMR2LH: <RIICn_base> + $000D_H$, RIICnMR2HL: <RIICn_base> + $000E_H$,
RIICnMR2HH: <RIICn_base> + $000F_H$

Initial Value: $0000\ 0006_H$ This register is initialized by any reset.

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	DLCS	SDA Output Delay Clock Source Selection 0: The internal reference clock (IICϕ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICϕ/2) is selected as the clock source of the SDA output delay counter.*1
6 to 4	SDDL[2:0]	SDA Output Delay Counter • When RIICnMR2.DLCS = 0 (IICϕ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICϕ cycle 0 1 0: 2 IICϕ cycles 0 1 1: 3 IICϕ cycles 1 0 0: 4 IICϕ cycles 1 0 1: 5 IICϕ cycles 1 1 0: 6 IICϕ cycles 1 1 1: 7 IICϕ cycles • When RIICnMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICϕ cycles 0 1 0: 3 or 4 IICϕ cycles 0 1 1: 5 or 6 IICϕ cycles 1 0 0: 7 or 8 IICϕ cycles
3	—	Reserved This bit is read as 0. The write value should be 0.
2	TMOH	Timeout H Count Control 0: Count is disabled while the SCL line is at a high level. 1: Count is enabled while the SCL line is at a high level.
1	TMOL	Timeout L Count Control 0: Count is disabled while the SCL line is at a low level. 1: Count is enabled while the SCL line is at a low level.

Table 18.9 RIICnMR2 register contents (2/2)

Bit Position	Bit Name	Function
0	TMOS	Timeout Detection Time Selection 0: Long mode is selected. 1: Short mode is selected.

Note 1. The setting DLCS = 1 (IICϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (RIICnFER.TMOE bit = 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCL line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.

For details on the timeout function, see Section 18.13.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (RIICnFER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (RIICnFER.TMOE bit = 1).

SDDL[2:0] Bits (SDA Output Delay Setup Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

For details on this function, see Section 18.7, Facility for Delaying SDA Output.

CAUTION

Set the SDA output delay time to meet the I2C bus standard (within the data enable time/acknowledge enable time*1) or the SMBus standard (within the data hold time: 300 [ns] or more, and SCL-clock low-level period - the data setup time: 250 [ns]). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

Note 1. Data enable time/acknowledge enable time
3,450 [ns] (0 to 100 [kbps]: standard mode (Sm))
900 [ns] (0 to 400 [kbps]: fast mode (Fm))

18.3.5 RIICnMR3 — I²C Bus Mode Register 3

Access: RIICnMR3 is a 32-bit readable/writable register.
RIICnMR3L and RIICnMR3H are 16-bit readable/writable registers.
RIICnMR3LL, RIICnMR3LH, RIICnMR3HL, and RIICnMR3HH are 8-bit readable/writable registers.

Address: RIICnMR3: <RIICn_base> + 0010_H
RIICnMR3L: <RIICn_base> + 0010_H, RIICnMR3H: <RIICn_base> + 0012_H
RIICnMR3LL: <RIICn_base> + 0010_H, RIICnMR3LH: <RIICn_base> + 0011_H, RIICnMR3HL: <RIICn_base> + 0012_H,
RIICnMR3HH: <RIICn_base> + 0013_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.10 RIICnMR3 register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	SMBE	SMBus/I²C Bus Selection 0: I²C bus selection 1: SMBus selection
6	WAIT*2	WAIT 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading RIICnDRR.
5	RDRFS*2	RDRF Flag Set Timing Selection 0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCL line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit.
4	ACKWP*1	ACKBT Write Protect 0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.
3	ACKBT*1	Transmit Acknowledge 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).
2	ACKBR	Receive Acknowledge 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).
1, 0	NF[1:0]	Noise Filter Stage Selection b1 b0 0 0: Noise of up to one IICϕ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICϕ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICϕ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICϕ cycles is filtered out (4-stage filter).

Note 1. If it is attempted to write 1 to both ACKWP and ACKBT bits, the ACKBT bit cannot be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Noise Filter Stage Selection)

These bits are used to select the noise width that can be eliminated for the signal input to RIICnSCL or RIICnSDA pin.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

When 1 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.

[Setting condition]

When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

CAUTION

The ACKBT bit must be written to while the ACKWP bit is 1. If the ACKBT bit is written to with the ACKWP bit cleared to 0, writing to the ACKBT bit is disabled.

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (RIICnDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL line is held low from the falling edge of the ninth clock cycle until the RIICnDRR value is read each time single-byte data is received. This enables receive operation in byte units.

CAUTION

When the value of the WAIT bit is to be read, be sure to read the RIICnDRR beforehand.

SMBE Bit (SMBus Select)

Setting this bit to 1 enables the RIICnSER.HOAE bit.

18.3.6 RIICnFER — I2C Bus Function Enable Register

Access: RIICnFER is a 32-bit readable/writable register.
RIICnFERL and RIICnFERH are 16-bit readable/writable registers.
RIICnFERLL, RIICnFERLH, RIICnFERHL, and RIICnFERHH are 8-bit readable/writable registers.

Address: RIICnFER: <RIICn_base> + 0014_H
RIICnFERL: <RIICn_base> + 0014_H, RIICnFERH: <RIICn_base> + 0016_H
RIICnFERLL: <RIICn_base> + 0014_H, RIICnFERLH: <RIICn_base> + 0015_H, RIICnFERHL: <RIICn_base> + 0016_H,
RIICnFERHH: <RIICn_base> + 0017_H

Initial Value: $0000\ 0072_H$ This register is initialized by any reset.

Table 18.11 RIICnFER register contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are read as 0. The write value should be 0.
6	SCLE	SCL Synchronous Circuit Enable 0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.
5	NFE	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.
4	NACKE	NACK Reception Transfer Suspension Enable 0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).
3	SALE	Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.
1	MALE	Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the RIICnCR2.MST and TRS bits automatically when arbitration is lost.)
0	TMOE	Timeout Function Enable 0: The timeout function is disabled. 1: The timeout function is enabled.

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, see Section 18.13.1, Timeout Function.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is cleared to 0 (SCL synchronous circuit not used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in RIICnBRH and RIICnBRL regardless of the SCL line state. For this reason, if the bus load of the I2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be cleared to 0 except for checking the output of the transfer rate.

18.3.7 RIICnSER — I2C Bus Status Enable Register

Access: RIICnSER is a 32-bit readable/writable register.
RIICnSERL and RIICnSERH are 16-bit readable/writable registers.
RIICnSERLL, RIICnSERLH, RRIICnSERHL, and RIICnSERHH are 8-bit readable/writable registers.

Address: RIICnSER: <RIICn_base> + 0018_H
RIICnSERL: <RIICn_base> + 0018_H, RIICnSERH: <RIICn_base> + $001A_H$
RIICnSERLL: <RIICn_base> + 0018_H, RIICnSERLH: <RIICn_base> + 0019_H, RIICnSERHL: <RIICn_base> + $001A_H$,
RIICnSERHH: <RIICn_base> + $001B_H$

Initial Value: 0000 0009_H This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.12 RIICnSER register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	HOAE	Host Address Enable 0: Host address detection is disabled. 1: Host address detection is enabled.
6	—	Reserved This bit is read as 0. The write value should be 0.
5	DIDE	Device-ID Address Detection Enable 0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.
4	—	Reserved This bit is read as 0. The write value should be 0.
3	GCE	General Call Address Enable 0: General call address detection is disabled. 1: General call address detection is enabled.
2	SAR2E	Slave Address Register 2 Enable 0: Slave address in RIICnSAR2 is disabled. 1: Slave address in RIICnSAR2 is enabled.
1	SAR1E	Slave Address Register 1 Enable 0: Slave address in RIICnSAR1 is disabled. 1: Slave address in RIICnSAR1 is enabled.
0	SAR0E	Slave Address Register 0 Enable 0: Slave address in RIICnSAR0 is disabled. 1: Slave address in RIICnSAR0 is enabled.

SARyE Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the received slave address and the slave address set in RIICnSARy.

When this bit is set to 1, the slave address set in RIICnSARy is enabled and is compared with the received slave address.

When this bit is cleared to 0, the slave address set in RIICnSARy is disabled and is ignored even if it matches the received slave address.

GCE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address ($0000\ 000_B$ + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs data receive operation.

When this bit is cleared to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID ($1111\ 100_B$) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is cleared to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, see **Section 18.9.3, Device-ID Address Detection**.

HOAE Bit (Host Address Enable)

This bit is used to specify whether to ignore received host address ($0001\ 000_B$) when the RIICnMR3.SMBS bit is 1.

When this bit is set to 1 while the RIICnMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs the receive operation.

When the RIICnMR3.SMBS bit or the HOAE bit is cleared to 0, the received slave address is ignored even if it matches the host address.

18.3.8 RIICnIER — I²C Bus Interrupt Enable Register

Access: RIICnIER is a 32-bit readable/writable register.
RIICnIERL and RIICnIERH are 16-bit readable/writable registers.
RIICnIERLL, RIICnIERLH, RIICnIERHL, and RIICnIERHH are 8-bit readable/writable registers.

Address: RIICnIER: <RIICn_base> + $001C_H$
RIICnIERL: <RIICn_base> + $001C_H$, RIICnIERH: <RIICn_base> + $001E_H$
RIICnIERLL: <RIICn_base> + $001C_H$, RIICnIERLH: <RIICn_base> + $001D_H$, RIICnIERHL: <RIICn_base> + $001E_H$,
RIICnIERHH: <RIICn_base> + $001F_H$

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Table 18.13 RIICnIER register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	TIE	Transmit Data Empty Interrupt Enable 0: Transmit data empty interrupt (INTRIICTI) request is disabled. 1: Transmit data empty interrupt (INTRIICTI) request is enabled.
6	TEIE	Transmit End Interrupt Enable 0: Transmit end interrupt (INTRIICTEI) request is disabled. 1: Transmit end interrupt (INTRIICTEI) request is enabled.
5	RIE	Receive Data Full Interrupt Enable 0: Receive data full interrupt (INTRIICRI) request is disabled. 1: Receive data full interrupt (INTRIICRI) request is enabled.
4	NAKIE	NACK Reception Interrupt Enable 0: NACK reception interrupt (INTRIICNAKI) request is disabled. 1: NACK reception interrupt (INTRIICNAKI) request is enabled.
3	SPIE	Stop Condition Detection Interrupt Enable 0: Stop condition detection interrupt (INTRIICSPI) request is disabled. 1: Stop condition detection interrupt (INTRIICSPI) request is enabled.
2	STIE	Start Condition Detection Interrupt Enable 0: Start condition detection interrupt (INTRIICSTI) request is disabled. 1: Start condition detection interrupt (INTRIICSTI) request is enabled.
1	ALIE	Arbitration-Lost Interrupt Enable 0: Arbitration-lost interrupt (INTRIICALI) request is disabled. 1: Arbitration-lost interrupt (INTRIICALI) request is enabled.
0	TMOIE	Timeout Interrupt Enable 0: Timeout interrupt (INTRIICTMOI) request is disabled. 1: Timeout interrupt (INTRIICTMOI) request is enabled.

TMOIE Bit (Timeout Interrupt Enable)

This bit is used to enable or disable timeout interrupt (INTRIICTMOI) requests when the RIICnSR2.TMOF flag is set to 1. An INTRIICTMOI interrupt request is canceled by clearing the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Enable)

This bit is used to enable or disable arbitration-lost interrupt (INTRIICALI) requests when the RIICnSR2.AL flag is set to 1. An INTRIICALI interrupt request is canceled by clearing the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Enable)

This bit is used to enable or disable start condition detection interrupt (INTRIICSTI) requests when the RIICnSR2.START flag is set to 1. An INTRIICSTI interrupt request is canceled by clearing the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Enable)

This bit is used to enable or disable stop condition detection interrupt (INTRIICSPI) requests when the RIICnSR2.STOP flag is set to 1. An INTRIICSPI interrupt request is canceled by clearing the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Enable)

This bit is used to enable or disable NACK reception interrupt (INTRIICNAKI) requests when the RIICnSR2.NACKF flag is set to 1. An INTRIICNAKI interrupt request is canceled by clearing the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Enable)

This bit is used to enable or disable receive data full interrupt (INTRIICRI) requests when the RIICnSR2.RDRF flag is set to 1. An INTRIICRI interrupt request is canceled by clearing the RDRF flag or the RIE bit to 0.

TEIE Bit (Transmit End Interrupt Enable)

This bit is used to enable or disable transmit end interrupts (INTRIICTEI) when the RIICnSR2.TEND flag is set to 1. An INTRIICTEI interrupt request is canceled by clearing the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit is used to enable or disable transmit data empty interrupts (INTRIICTI) when the RIICnSR2.TDRE flag is set to 1.

18.3.9 RIICnSR1 — I2C Bus Status Register 1

Access: RIICnSR1 is a 32-bit readable/writable register.
RIICnSR1L and RIICnSR1H are 16-bit readable/writable registers.
RIICnSR1LL, RIICnSR1LH, RIICnSR1HL, and RIICnSR1HH are 8/1-bit readable/writable registers.

Address: RIICnSR1: <RIICn_base> + 0020_H
RIICnSR1L: <RIICn_base> + 0020_H, RIICnSR1H: <RIICn_base> + 0022_H
RIICnSR1LL: <RIICn_base> + 0020_H, RIICnSR1LH: <RIICn_base> + 0021_H, RIICnSR1HL: <RIICn_base> + 0022_H, RIICnSR1HH: <RIICn_base> + 0023_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Note 1. Only 0 can be written to this bit.

Table 18.14 RIICnSR1 register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	HOA	Host Address Detection Flag 0: Host address is not detected. 1: Host address is detected.
6	—	Reserved This bit is read as 0. The write value should be 0.
5	DID	Device-ID Address Detection Flag 0: Device-ID command is not detected. 1: Device-ID command is detected.
4	—	Reserved This bit is read as 0. The write value should be 0.
3	GCA	General Call Address Detection Flag 0: General call address is not detected. 1: General call address is detected.
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 is not detected. 1: Slave address 2 is detected.
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 is not detected. 1: Slave address 1 is detected.
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 is not detected. 1: Slave address 0 is detected.

AASy Flag (Slave Address y Detection) (y = 0 to 2)

[Setting conditions]

<For 7-bit address format: RIICnSARy.FSy = 0>

When the received slave address matches the RIICnSARy.SVA[7:1] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address matches the RIICnSARy.SVA[7:0] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

<For 7-bit address format: RIICnSARy.FSy = 0>

- When the received slave address does not match the RIICnSARy.SVA[7:1] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

- When the received slave address does not match a value of (1111 0_B + RIICnSARy.SVA[9:8]) with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address does not match the RIICnSARy.SVA[7:0] value with the RIICnSER.SARyE bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection)

[Setting condition]

When the received slave address matches the general call address (0000 000_B + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000_B + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection)

[Setting condition]

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.
- When a restart condition is detected after a match with the device ID address and the device ID address ($1111\ 100_B$) + 1 [R] has matched with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID ($1111\ 100_B$)) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

HOA Flag (Host Address Detection)

[Setting condition]

When the received slave address matches the host address ($0001\ 000_B$) while the RIICnMR3.SMBE bit and RIICnSER.HOAE bit are set to 1 (host address detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA bit after reading HOA = 1
- When a stop condition is detected
- When 0 is written to the RIICnMR3.SMBE bit or the RIICnSER.HOAE bit
- When the received slave address does not match the host address ($0001\ 000_B$) with the RIICnSER.HOAE bit set to 1 (host address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

18.3.10 RIICnSR2 — I2C Bus Status Register 2

Access: RIICnSR2 is a 32-bit readable/writable register.
RIICnSR2L and RIICnSR2H are 16-bit readable/writable registers.
RIICnSR2LL, RIICnSR2LH, RIICnSR2HL, and RIICnSR2HH are 8/1-bit readable/writable registers.

Address: RIICnSR2: <RIICn_base> + 0024_H
RIICnSR2L: <RIICn_base> + 0024_H, RIICnSR2H: <RIICn_base> + 0026_H
RIICnSR2LL: <RIICn_base> + 0024_H, RIICnSR2LH: <RIICn_base> + 0025_H, RIICnSR2HL: <RIICn_base> + 0026_H, RIICnSR2HH: <RIICn_base> + 0027_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1	R(/W)*1

Note 1. Only 0 can be written to this bit.

Table 18.15 RIICnSR2 register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7	TDRE	Transmit Data Empty Flag 0: RIICnDRT contains transmit data. 1: RIICnDRT contains no transmit data.
6	TEND	Transmit End Flag 0: Data is being transmitted. 1: Data has been transmitted.
5	RDRF	Receive Data Full Flag 0: RIICnDRR contains no receive data. 1: RIICnDRR contains receive data.
4	NACKF	NACK Receive Flag 0: NACK is not received. 1: NACK is received.
3	STOP	Stop Condition Detection Flag 0: Stop condition is not detected. 1: Stop condition is detected.
2	START	Start Condition Detection Flag 0: Start condition is not detected. 1: Start condition is detected.
1	AL	Arbitration-Lost Flag 0: Arbitration is not lost. 1: Arbitration is lost.
0	TMOF	Timeout Flag 0: Timeout has not occurred. 1: Timeout occurred.

TMOF Flag (Timeout)

This flag is set to 1 when the RIIC recognizes timeout after the SCL line state remains unchanged for a certain period.

[Setting condition]

The timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is held low or high during the following conditions:

- The bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1).
- The slave address matches that of this module (RIICnSR1 register is not 00_H) and the bus is busy (RIICnCR2.BBSY = 1) in slave mode (RIICnCR2.MST = 0).
- Issuing of a start condition is being requested (RIICnCR2.ST = 1) and the bus is free (RIICnCR2.BBSY = 0).

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDA line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL bit to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

<When master arbitration-lost detection is enabled: RIICnFER.MALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high-impedance state))
- When a start condition is detected while the RIICnCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDA line level
- When the RIICnCR2.ST bit is set to 1 (start condition issuance request) with the RIICnCR2.BBSY flag set to 1.

<When NACK arbitration-lost detection is enabled: RIICnFER.NALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

<When slave arbitration-lost detection is enabled: RIICnFER.SALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL bit after reading AL = 1

- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 18.16 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

RIICnFER			RIICnSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	x	x	1	Start condition issuance error	When internal SDA output state does not match SDA line level when a start condition is detected while the RIICnCR2.ST bit is 1
					When RIICnCR2.ST is set to 1 with RIICnCR2.BBSY set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
x	1	x	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
x	x	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

x: Don't care

START Flag (Start Condition Detection)

[Setting condition]

When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection)

[Setting condition]

When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Receive)

[Setting condition]

When acknowledge is not received (NACK is received) from the receive device in transmit mode with the RIICnFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to RIICnDRT in transmit mode or reading from RIICnDRR in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, clear the NACKF flag to 0.

RDRF Flag (Receive Data Full)

[Setting conditions]

- Slave receive mode
  - When the received slave address matches and the RIICnCR2.TRS bit is cleared to 0 after a start condition (or a restart condition) is detected
  - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR
- Master receive mode
  - When the slave address and the data direction are transmitted and the receive mode is entered (the RIICnCR2.TRS bit is set to 1) after a start condition (or a restart condition) is issued
  - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from RIICnDRR
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End)

[Setting condition]

At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to RIICnDRT
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty)

[Setting conditions]

- When data has been transferred from RIICnDRT to RIICnDRS and RIICnDRT becomes empty
- When the RIICnCR2.TRS bit is set to 1
  - When the RIICnCR2.MST bit is set to 1 after a start condition (or a restart condition) is detected
  - When the RIIC enters transmit mode from receive mode
- When the received slave address matches while the TRS bit is 1

[Clearing conditions]

- When data is written to RIICnDRT
- When the RIICnCR2.TRS bit is cleared to 0
  - When a stop condition is detected
  - When the RIIC enters receive mode from transmit mode
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1 while the RIICnFER.NACKE bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the RIICnDRS register and the RIICnDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

18.3.11 RIICnSARy — I2C Slave Address Register y (y = 0 to 2)

Access: RIICnSARy is a 32-bit readable/writable register.
RIICnSARyL and RIICnSARyH are 16-bit readable/writable registers.
RIICnSARyLL, RIICnSARyLH, RIICnSARyHL, and RIICnSARyHH are 8-bit readable/writable registers.

Address: RIICnSAR0: <RIICn_base> + 0028_H
RIICnSAR0L: <RIICn_base> + 0028_H, RIICnSAR0H: <RIICn_base> + $002A_H$
RIICnSAR0LL: <RIICn_base> + 0028_H, RIICnSAR0LH: <RIICn_base> + 0029_H, RIICnSAR0HL: <RIICn_base> + $002A_H$, RIICnSAR0HH: <RIICn_base> + $002B_H$
RIICnSAR1: <RIICn_base> + $002C_H$
RIICnSAR1L: <RIICn_base> + $002C_H$, RIICnSAR1H: <RIICn_base> + $002E_H$
RIICnSAR1LL: <RIICn_base> + $002C_H$, RIICnSAR1LH: <RIICn_base> + $002D_H$, RIICnSAR1HL: <RIICn_base> + $002E_H$, RIICnSAR1HH: <RIICn_base> + $002F_H$
RIICnSAR2: <RIICn_base> + 0030_H
RIICnSAR2L: <RIICn_base> + 0030_H, RIICnSAR2H: <RIICn_base> + 0032_H
RIICnSAR2LL: <RIICn_base> + 0030_H, RIICnSAR2LH: <RIICn_base> + 0031_H, RIICnSAR2HL: <RIICn_base> + 0032_H, RIICnSAR2HH: <RIICn_base> + 0033_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	FSy	—	—	—	—	—	SVA[9:1]									SVA0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.17 RIICnSARy register contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are read as 0. The write value should be 0.
15	FSy	7-Bit/10-Bit Address Format Selection 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.
14 to 10	—	Reserved These bits are read as 0. The write value should be 0.
9 to 1	SVA[9:1]	7-Bit Address/10-Bit Address Upper Bits A slave address is set. • When the FSy bit is 0 (7-bit address format), the SVA[7:1] bits are Valid and form a 7-bit slave address. • When the FSy bit is 1 (10-bit address format), SVA[9:1] bits form a 10-bit slave address (combined with the SVA0 bit).
0	SVA0	10-Bit Address LSB The least significant bit (LSB) of a 10-bit slave address is set. • When the FSy bit is 0 (7-bit address format), this bit is invalid. • When the FSy bit is 1 (10-bit address format), this bit is a 10-bit slave address (combined with the SVA[9:1] bits).

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (RIICnSARy.FSy = 1), this bit functions as the LSB of a 10-bit address and forms a 10-bit address in combination with the SVA[9:1] bits.
When the RIICnSER.SARyE bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, this bit is valid. While the RIICnSARy.FSy bit or SARyE bit is 0, the setting of this bit is ignored.

SVA[9:1] Bits (7-Bit Address/10-Bit Address Upper Bits)

When the 7-bit address format is selected (RIICnSARy.FSy = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (RIICnSARy.FSy = 1), these bits function as a 10-bit address in combination with the SVA0 bit.
While the RIICnSER.SARyE bit is 0, the setting of these bits is ignored.

FSy Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in RIICnSARy).

When the RIICnSER.SARyE bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 0, the 7-bit address format is selected for slave address y, the RIICnSARy.SVA[7:1] setting is valid, and the settings of the SVA[9:8] bits and the RIICnSARy.SVA0 bit are ignored.

When the RIICnSER.SARyE bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[9:1] bits and the SVA0 bit are valid.

While the RIICnSER.SARyE bit is 0 (RIICnSARy disabled), the setting of the RIICnSARy.FSy bit is invalid.

18.3.12 RIICnBRL — I2C Bus Bit Rate Low-Level Register

Access: RIICnBRL is a 32-bit readable/writable register.
RIICnBRLL and RIICnBRLH are 16-bit readable/writable registers.
RIICnBRLLL, RIICnBRLLH, RIICnBRLHL, and RIICnBRLHH are 8-bit readable/writable registers.

Address: RIICnBRL: <RIICn_base> + 0034_H
RIICnBRLL: <RIICn_base> + 0034_H, RIICnBRLH: <RIICn_base> + 0036_H
RIICnBRLLL: <RIICn_base> + 0034_H, RIICnBRLLH: <RIICn_base> + 0035_H, RIICnBRLHL: <RIICn_base> + 0036_H, RIICnBRLHH: <RIICn_base> + 0037_H

Initial Value: 0000 $00FF_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.18 RIICnBRL register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7 to 5	—	Reserved These bits are read as 1. The write value should be 1.
4 to 0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock

The RIICnBRL register is a 5-bit register that is used to set the width at low level for the SCL clock.

It also works to generate the data setup time for automatic SCL low-hold operation (see Section 18.10, Automatically Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value equal to or longer than the data setup time*1.

RIICnBRL counts the low-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

Note 1. Data setup time ($t_{SU: DAT}$)
250 [ns] (0 to 100 [kbps]: standard mode (Sm))
100 [ns] (0 to 400 [kbps]: fast mode (Fm))

18.3.13 RIICnBRH — I2C Bus Bit Rate High-Level Register

Access: RIICnBRH is a 32-bit readable/writable register.
RIICnBRHL and RIICnBRHH are 16-bit readable/writable registers.
RIICnBRHLL, RIICnBRHLH, RIICnBRHHL, and RIICnBRHHH are 8-bit readable/writable registers.

Address: RIICnBRH: <RIICn_base> + 0038_H
RIICnBRHL: <RIICn_base> + 0038_H, RIICnBRHH: <RIICn_base> + $003A_H$
RIICnBRHLL: <RIICn_base> + 0038_H, RIICnBRHLH: <RIICn_base> + 0039_H, RIICnBRHHL: <RIICn_base> + $003A_H$,
RIICnBRHHH:<RIICn_base> + $003B_H$

Initial Value: 0000 $00FF_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	BRH[4:0]				
Initial value	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 18.19 RIICnBRH register contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are read as 0. The write value should be 0.
7 to 5	—	Reserved These bits are read as 1. The write value should be 1.
4 to 0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock

RIICnBRH is a 5-bit register to set the high-level period of SCL clock. RIICnBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.

RIICnBRH counts the high-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

The frequency and duty cycle are calculated using one of the following expressions (1) to (5) according to the register settings.

CAUTION

The minimum value that can be specified in RIICnBRL and RIICnBRH is determined according to the values of the SCLE and NFE bits in RIICnFER and the NF bit in RIICnMR3. For details of the minimum specifiable value, see Table 18.20.

(1) When SCLE = 0

Frequency = 1 / {[(BRH + 1) + (BRL + 1)] / IICϕ + tr + tf}

Duty cycle = {tr + (BRH + 1) / IICϕ} / {tr + tf + [(BRH + 1) + (BRL + 1)] / IICϕ}

(2) When SCLE = 1, NFE = 0, CKS = 000 (IICϕ = P0ϕ)
Frequency = 1 / {[(BRH + 3) + (BRL + 3)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 3) / IICϕ} / {tr + tf + [(BRH + 3) + (BRL + 3)] / IICϕ}

(3) When SCLE = 1, NFE = 1, CKS = 000 (IICϕ = P0ϕ)
Frequency = 1 / {[(BRH + 3 + nf) + (BRL + 3 + nf)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 3 + nf) / IICϕ} / {tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)] / IICϕ}

(4) When SCLE = 1, NFE = 0, CKS ≠ 000 (IICϕ < P0ϕ)
Frequency = 1 / {[(BRH + 2) + (BRL + 2)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 2) / IICϕ} / {tr + tf + [(BRH + 2) + (BRL + 2)] / IICϕ}

(5) When SCLE = 1, NFE = 1, CKS ≠ 000 (IICϕ < P0ϕ)
Frequency = 1 / {[(BRH + 2 + nf) + (BRL + 2 + nf)] / IICϕ + tr + tf}
Duty cycle = {tr + (BRH + 2 + nf) / IICϕ} / {tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)] / IICϕ}

Symbols in the expressions

SCLE: RIICnFER.SCLE bit

BRH: RIICnBRH.BRH[4:0] bits

BRL: RIICnBRL.BRL[4:0] bits

CKS: RIICnMR1.CKS bits

NFE: RIICnFER.NFE bit

IICϕ: Internal reference clock selected by the CKS bits

tf: SCL signal falling time [s] *1

tr: SCL signal rising time [s] *1

nf: Number of digital noise filter stages specified in the RIICnMR3.NF[0.1] bits

Note 1. The rising time (tr) and falling time (tf) of the SCL signal depend on the total capacitance of the bus line (Cb) and pull-up resistor (Rp). For details, see I²C Bus Standard from NXP Semiconductors.

Table 18.20 Minimum Specifiable Value for RIICnBRL and RIICnBRH

SCLE	NFE	nf	Minimum Pulse Width that Passes through Digital Filter	Minimum Specifiable Value for BRH and BRL	Pulse Width when Minimum Value is Specified
0	0	—	1 × IICϕ	1	2 × IICϕ
0	1	1	2 × IICϕ	2	3 × IICϕ
0	1	2	3 × IICϕ	3	4 × IICϕ
0	1	3	4 × IICϕ	4	5 × IICϕ
0	1	4	5 × IICϕ	5	6 × IICϕ
IICϕ cycle > P0ϕ cycle (CKS ≠ 000)					
1	0	—	1 × IICϕ	0	2 × IICϕ
1	1	1	2 × IICϕ	1	4 × IICϕ
1	1	2	3 × IICϕ	2	6 × IICϕ

Table 18.20 Minimum Specifiable Value for RIICnBRL and RIICnBRH

SCLE	NFE	nf	Minimum Pulse Width that Passes through Digital Filter	Minimum Specifiable Value for BRH and BRL	Pulse Width when Minimum Value is Specified
1	1	3	4 × IICϕ	3	8 × IICϕ
1	1	4	5 × IICϕ	4	10 × IICϕ
IICϕ cycle = P0ϕ cycle (CKS = 000)					
1	0	—	2 × P0ϕ	0	3 × IICϕ
1	1	1	3 × P0ϕ	1	5 × IICϕ
1	1	2	4 × P0ϕ	2	7 × IICϕ
1	1	3	5 × P0ϕ	3	9 × IICϕ

18.3.14 RIICnDRT — I2C Bus Transmit Data Register

Access: RIICnDRT is a 32-bit readable/writable register.
RIICnDRTL and RIICnDRTH are 16-bit readable/writable registers.
RIICnDRTLL, RIICnDRTLH, RIICnDRTHL, and RIICnDRTHH are 8-bit readable/writable registers.

Address: RIICnDRT: <RIICn_base> + $003C_H$
RIICnDRTL: <RIICn_base> + $003C_H$, RIICnDRTH: <RIICn_base> + $003E_H$
RIICnDRTLL: <RIICn_base> + $003C_H$, RIICnDRTLH: <RIICn_base> + $003D_H$, RIICnDRTHL: <RIICn_base> + $003E_H$,
RIICnDRTHH: <RIICn_base> + $003F_H$

Initial Value: 0000 $00FF_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When RIICnDRT detects a space in the I2C bus shift register (RIICnDRS), it transfers the transmit data that has been written to RIICnDRT to RIICnDRS and starts transmitting data in transmit mode.

The double-buffer structure of RIICnDRT and RIICnDRS allows continuous transmit operation if the next transmit data has been written to RIICnDRT while the RIICnDRS data is being transmitted.

RIICnDRT can always be read and written. Write transmit data to RIICnDRT once when a transmit data empty interrupt (INTRIICTI) request is generated. When writing to bits 8 to 15, be sure to write 0 to these bits.

18.3.15 RIICnDRR — I2C Bus Receive Data Register

Access: RIICnDRR is a 32-bit readable/writable register.
RIICnDRRL and RIICnDRRH are 16-bit readable/writable registers.
RIICnDRRLL, RIICnDRRLH, RIICnDRRHL, and RIICnDRRHH are 8-bit readable/writable registers.

Address: RIICnDRR: <RIICn_base> + 0040_H
RIICnDRRL: <RIICn_base> + 0040_H, RIICnDRRH: <RIICn_base> + 0042_H
RIICnDRRLL: <RIICn_base> + 0040_H, RIICnDRRLH: <RIICn_base> + 0041_H, RIICnDRRHL: <RIICn_base> + 0042_H,
RIICnDRRHH: <RIICn_base> + 0043_H

Initial Value: $0000\ 0000_H$ This register is initialized by any reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	DRR[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

When 1 byte of data has been received, the received data is transferred from the I2C bus shift register (RIICnDRS) to RIICnDRR to enable the next data to be received.

The double-buffer structure of RIICnDRS and RIICnDRR allows continuous receive operation if the received data has been read from RIICnDRR while RIICnDRS is receiving data.

RIICnDRR cannot be written. Read data from RIICnDRR once when a receive data full interrupt (INTRIICRI) request is generated.

If DRR receives the next receive data before the current data is read from RIICnDRR (while the RIICnSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RDRF flag is set to 1 next.

18.3.16 RIICnDRS — I2C Bus Shift Register

Access: This register is not accessible.

Address: —

Initial Value: 0000 00FF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRS[7:0]							
Initial value	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

RIICnDRS is an 8-bit shift register to transmit and receive data.

During transmission, transmit data is transferred from RIICnDRT to RIICnDRS and is sent from the SDA pin. During reception, data is transferred from RIICnDRS to RIICnDRR after 1 byte of data has been received.

RIICnDRS cannot be accessed directly.

18.4 Interrupt Sources

The RIIC issues eight types of interrupt requests: transmission complete, receive data full, transmit data empty, detection of a stop condition, detection of a start condition, reception of a NACK, arbitration lost, and timeout.

Table 18.23 lists details of the interrupt requests. The receive data full and transmit data empty interrupt sources are both capable of launching data transfer by starting the DMAC.

Table 18.23 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMAC Launching	Priority*1	Interrupt Condition
INTRIICTEI	Transmission complete	TEND	Not possible	High	TEND = 1 • TEIE = 1
INTRIICRI	Receive data full	RDRF	Possible	↑	RDRF = 1 • RIE = 1
INTRIICTI	Transmit data empty	TDRE	Possible		TDRE = 1 • TIE = 1
INTRIICSPI	Detection of a stop condition	STOP	Not possible		STOP = 1 • SPIE = 1
INTRIICSTI	Detection of a start condition	START	Not possible		START = 1 • STIE = 1
INTRIICNAKI	Reception of a NACK	NACKF	Not possible		NACKF = 1 • NAKIE = 1
INTRIICALI	Arbitration lost	AL	Not possible		AL = 1 • ALIE = 1
INTRIICTMOI	Timeout	TMOF	Not possible	Low	TMOF = 1 • TMOIE = 1

Note 1. When the setting value of the interrupt priority register (ICDIPRn) is the same

Clear or mask the each flag during interrupt handling.

CAUTIONS

1. There is a latency (delay) between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt processing. Returning from interrupt processing without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.
2. The INTRIICRI and INTRIICTI interrupts do not need to be cleared because they are edge interrupts.
3. When using the INTRIICTEI interrupt, clear the RIICnSR2.TEND flag in the INTRIICTEI interrupt processing.
4. When using the INTRIICSPI interrupt, clear the RIICnSR2.STOP flag in the INTRIICSPI interrupt processing.
5. When using the INTRIICSTI interrupt, clear the RIICnSR2.START flag in the INTRIICSTI interrupt processing.
6. When using the INTRIICNAKI interrupt, clear the RIICnSR2.NACKF flag in the INTRIICNAKI interrupt processing.
7. When using the INTRIICALI interrupt, clear the RIICnSR2.AL flag in the INTRIICALI interrupt processing.
8. When using the INTRIICTMOI interrupt, clear the RIICnSR2.TMOF flag in the INTRIICTMOI interrupt processing.

18.5 Operation

18.5.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge (one frame). After a start condition or restart condition is issued, the master device sends the slave address and data direction in the first frame. The specified slave is valid until a stop condition is issued or a new slave is specified by a restart condition.

Figure 18.3 shows the I2C bus format, and Figure 18.4 shows the I2C bus timing.

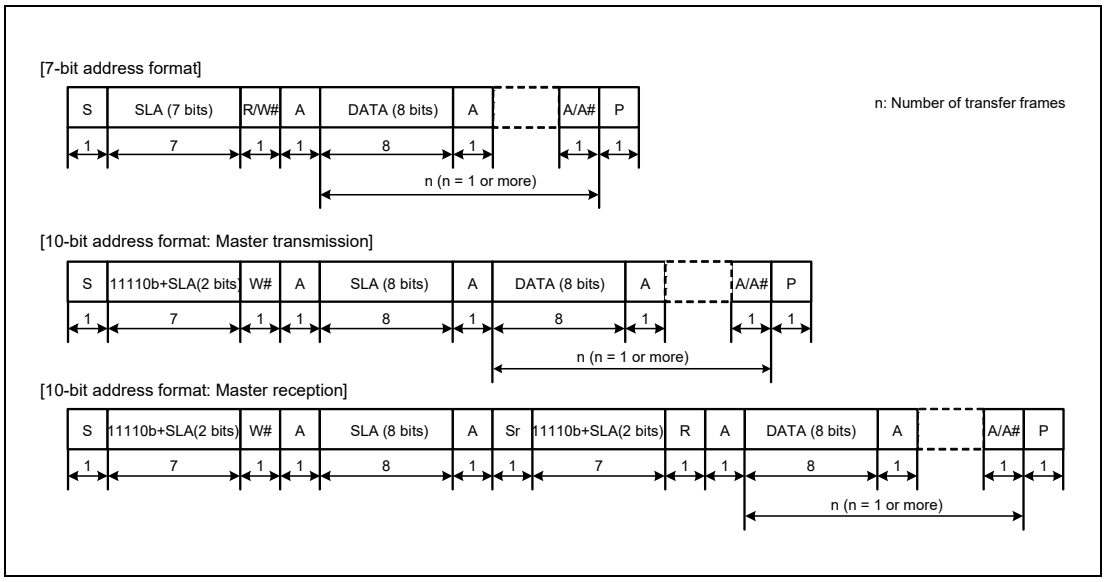

Figure 18.3 I2C Bus Format

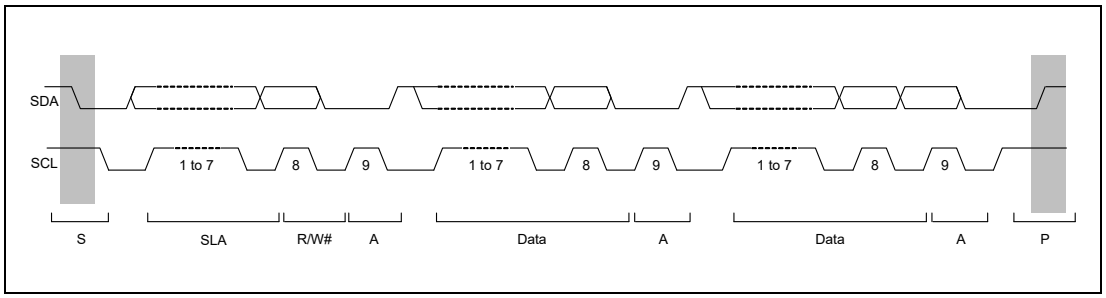

Figure 18.4 I2C Bus Timing (SLA = 7 Bits)

S: Start condition. The master device drives the SDA line low from high level while the SCL line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not-acknowledge. The receiving device has not returned a response or is not present so the SDA line has remained at the high level.

Sr: Restart condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

18.5.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 18.5.

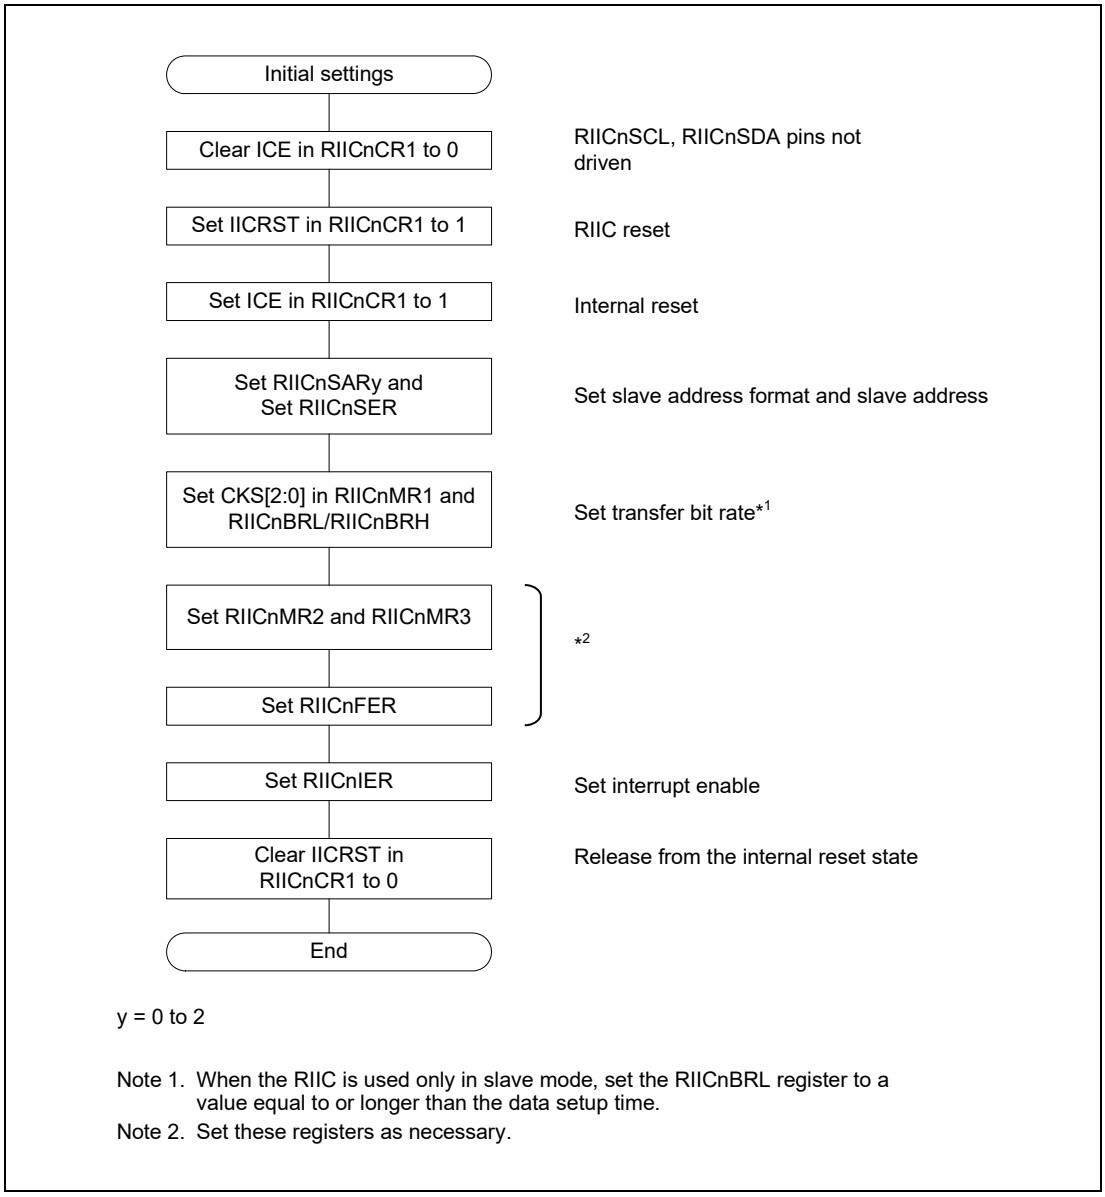

Figure 18.5 Example of RIIC Initialization Flowchart

18.5.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL (clock) and transmitted data signals as the master device, and the slave device returns acknowledgements. Figure 18.6 shows an example of usage of master transmission and Figure 18.7 to Figure 18.9 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

(1) Set the RIICnCR1.IICRST bit 1 to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 18.5). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0_B, the two higher-order bits of the slave address, and W# to RIICnDRT as the first address transmission. Then, as the second address transmission, write the eight lower-order bits of the slave address to RIICnDRT.

(4) After confirming that the RIICnSR2.TDRE flag is 1, write the data for transmission to the RIICnDRT register. The RIIC automatically holds the SCL line low until the data for transmission are ready or a stop condition is issued.

(5) After the last byte of the data to be transmitted is written to RIICnDRT register, wait until the value of the RIICnSR2.TEND flag returns to 1, and then set the RIICnCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.

(6) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, it automatically clears the RIICnSR2.TDRE and TEND flags to 0, and sets the RIICnSR2.STOP flag in to 1.

(7) Clear the RIICnSR2.NACKF and STOP flags to 0.

CAUTION

Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

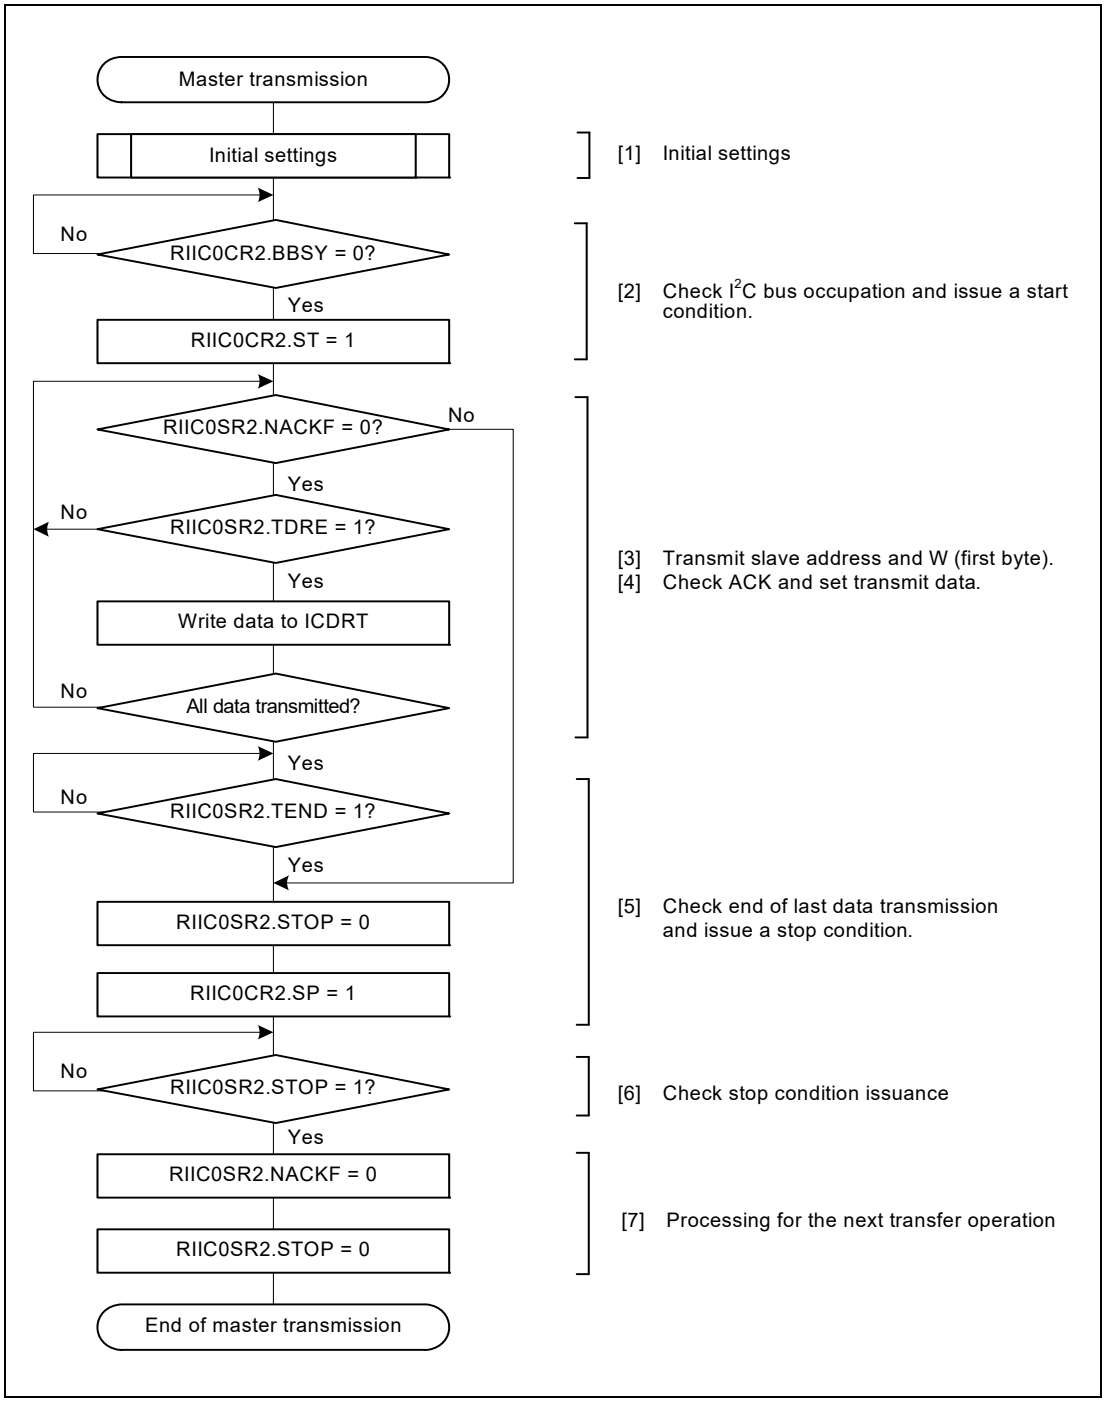

Figure 18.6 Example of Master Transmission Flowchart

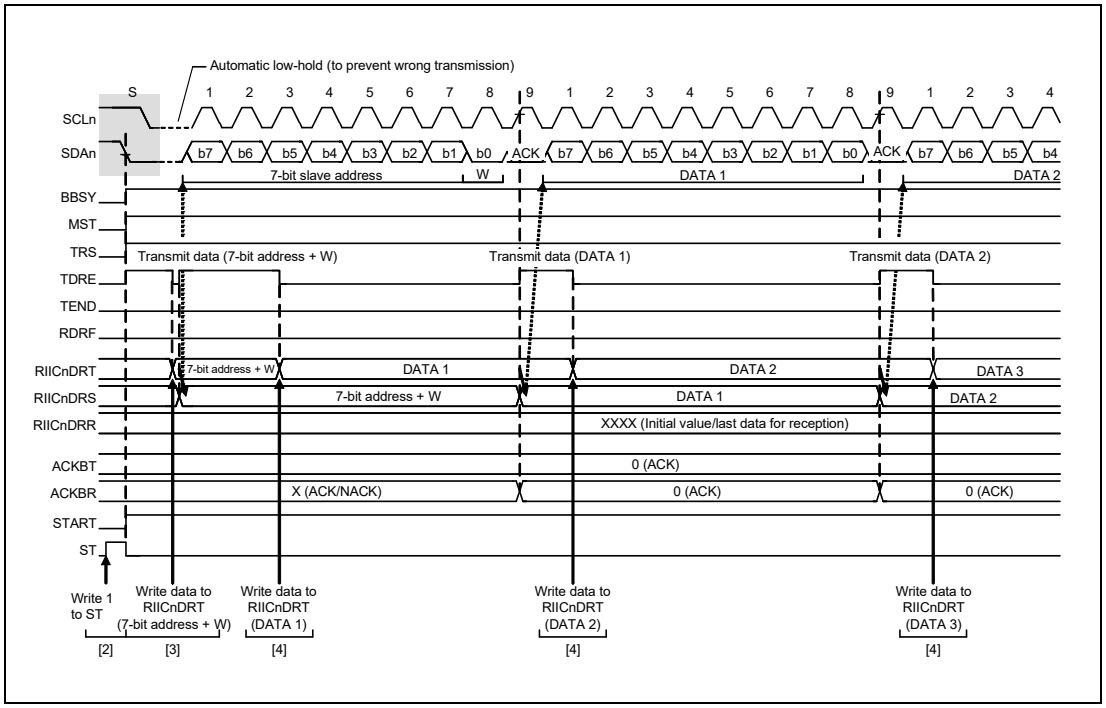

Figure 18.7 Master Transmit Operation Timing (1) (7-Bit Address Format)

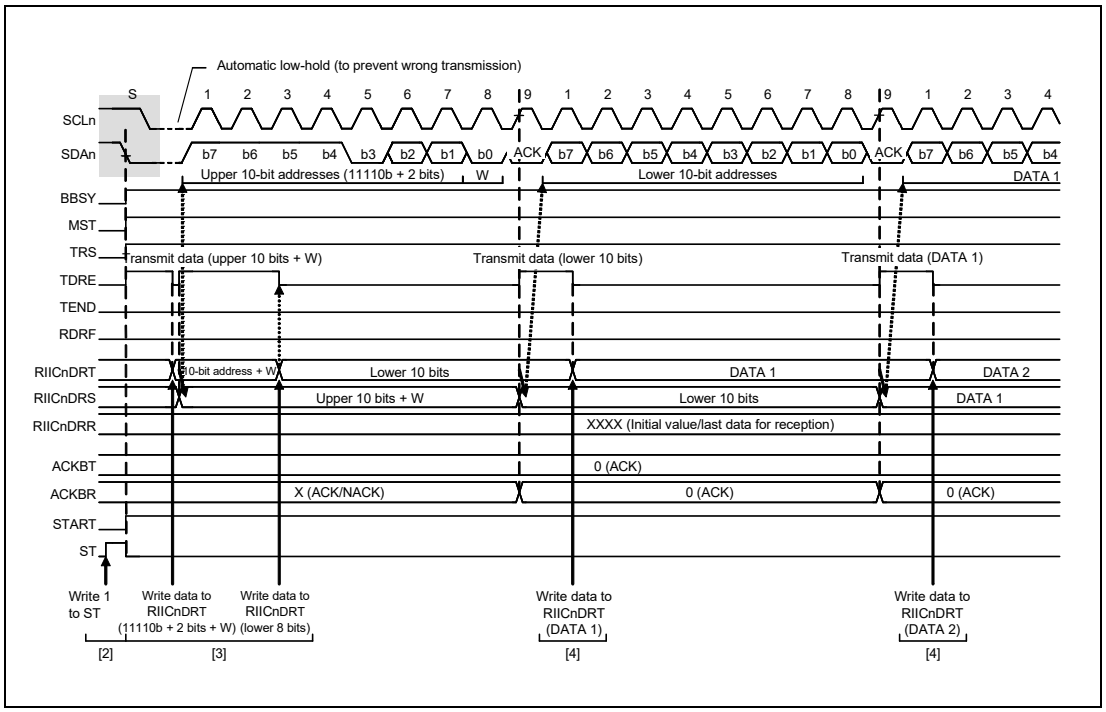

Figure 18.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

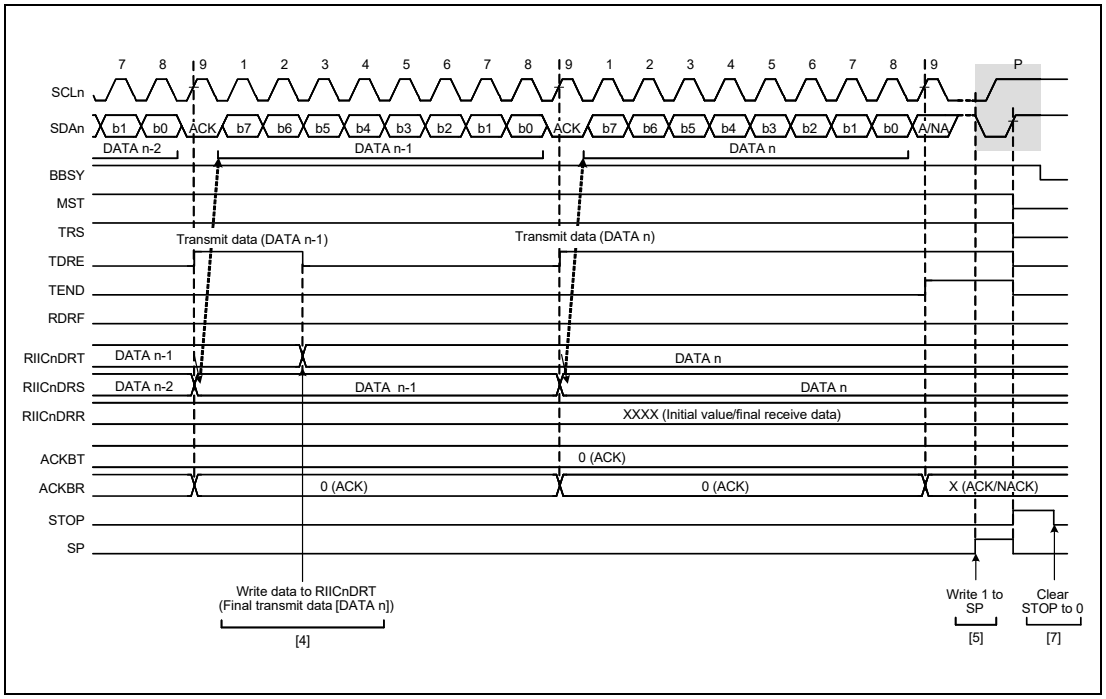

Figure 18.9 Master Transmit Operation Timing (3)

18.5.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL (clock) signal, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 18.10 shows an example of usage for the master reception of 3 or more bytes (7-bit address format), Figure 18.14 shows an example of usage for the master reception of 1 or 2 bytes (7-bit address format), and Figure 18.11 to Figure 18.13 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

(1) Set the RIICnCR1.IICRST bit to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 18.5). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the RIICnCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the RIICnCR2.TRS bit is cleared to 0 on the rising edge of the ninth cycle of SCL (the clock signal), placing the RIIC in master receive mode. At this time, the TDRE flag is automatically cleared to 0 and the RIICnSR2.RDRF flag is automatically set to 1.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0_B, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

(4) Dummy read RIICnDRR after confirming that the RIICnSR2.RDRF flag is 1; this makes the RIIC start output of the SCL (clock) signal and start data reception.

(5) After 1 byte of data has been received, the RIICnSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RIICnMR3.RDRFS bit. Reading out RIICnDRR at this time will produce the received data, and the RDRF flag is

automatically cleared to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the RIICnMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the RIICnMR3.WAIT bit to 1 (for wait insertion) before reading the RIICnDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the RIICnMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

(6) When the RIICnMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the RIICnMR3.ACKBT bit to 1 (NACK).

(7) After reading out the byte before last from the RIICnDRR register, if the value of the RIICnSR2.RDRF flag is confirmed to be 1, write 1 to the RIICnCR2.SP bit (stop condition issuance request) and then read the last byte from RIICnDRR. When RIICnDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the RIICnSR2.STOP flag to 1.

(9) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

18.5.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL (clock) signal, the RIIC transmits data as a slave device, and the master device returns acknowledgements.

Figure 18.15 shows an example of usage of slave transmission and Figure 18.16 and Figure 18.17 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Follow the procedure in Figure 18.5 to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the RIICnCR2.TRS bit and the RIICnSR2.TDRE flag to 1.

(3) After the RIICnSR2.TEND flag is confirmed to be 1, write the data for transmission to the RIICnDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the RIICnFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait unit the RIICnSR2.TEND flag is set to 1 while the RIICnSR2.TDRE flag is 1, after the RIICnSR2.NACKF flag is set to 1 or the last byte for transmission is written to the RIICnDRT register. When the RIICnSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL line low on the ninth falling edge of SCL clock.

(5) When the RIICnSR2.NACKF flag or the RIICnSR2.TEND flag is 1, dummy read RIICnDRR to complete the processing. This releases the SCL line.

(6) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2), flags RIICnSR2.TDRE and TEND, and the RIICnCR2.TRS bit to 0, and enters slave receive mode.

(7) Clear the RIICnSR2.NACKF and STOP flags to 0.

CAUTION

Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

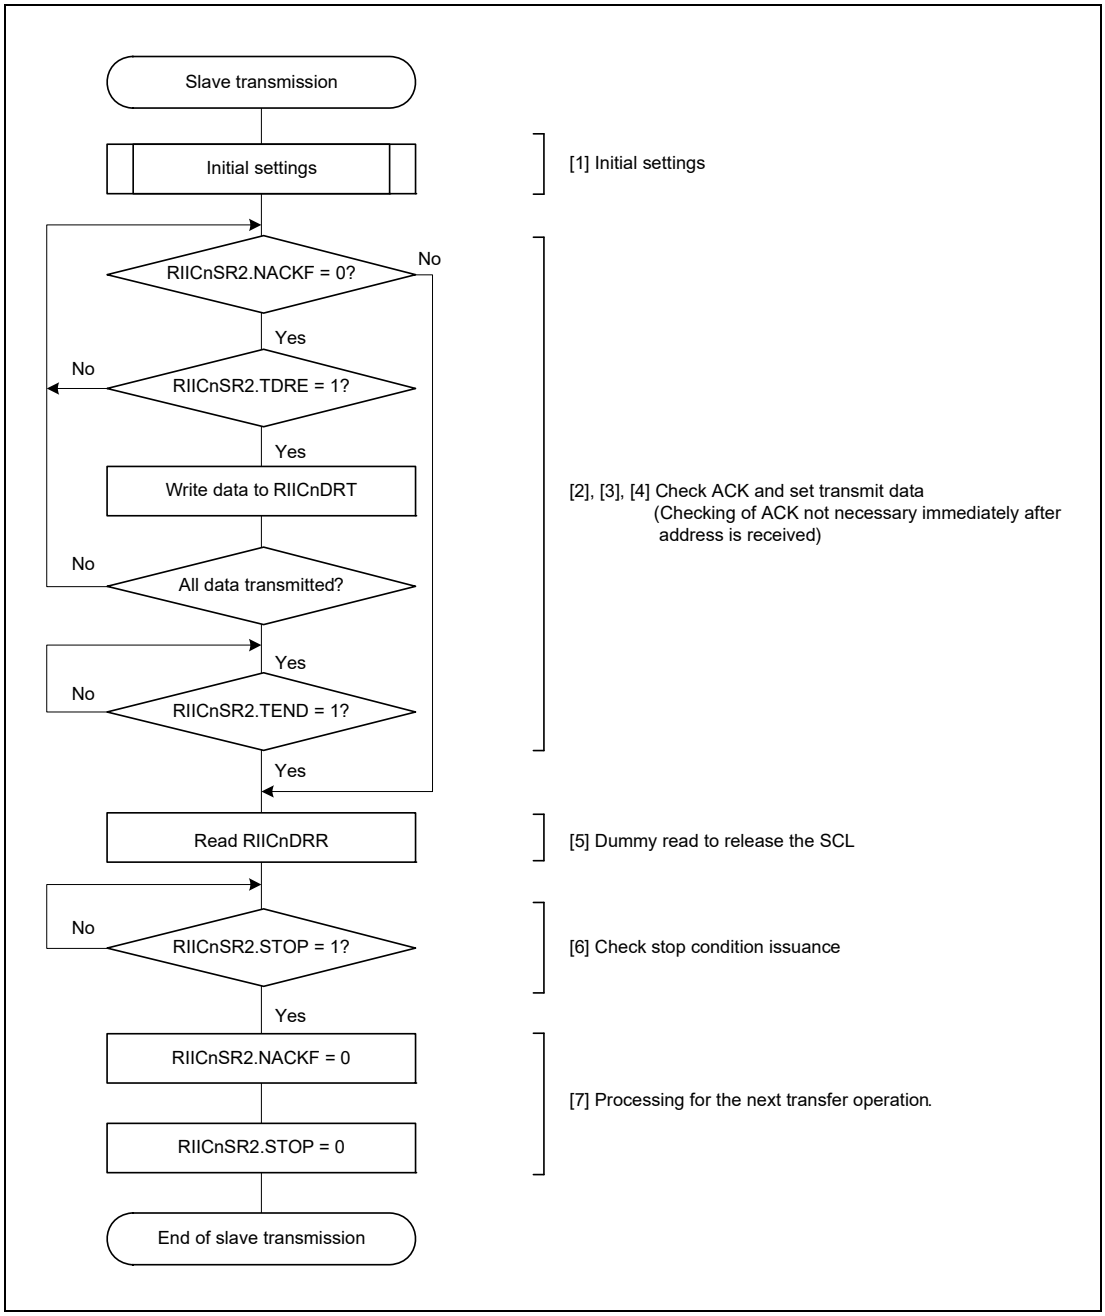

Figure 18.15 Example of Slave Transmission Flowchart

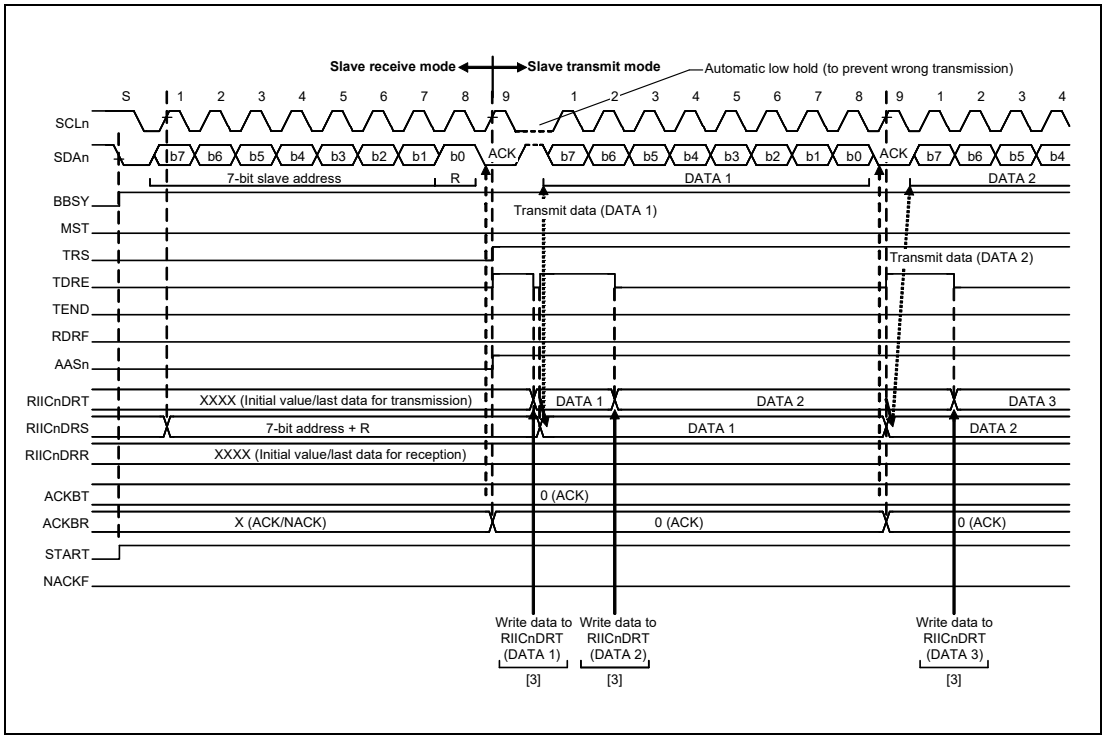

Figure 18.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

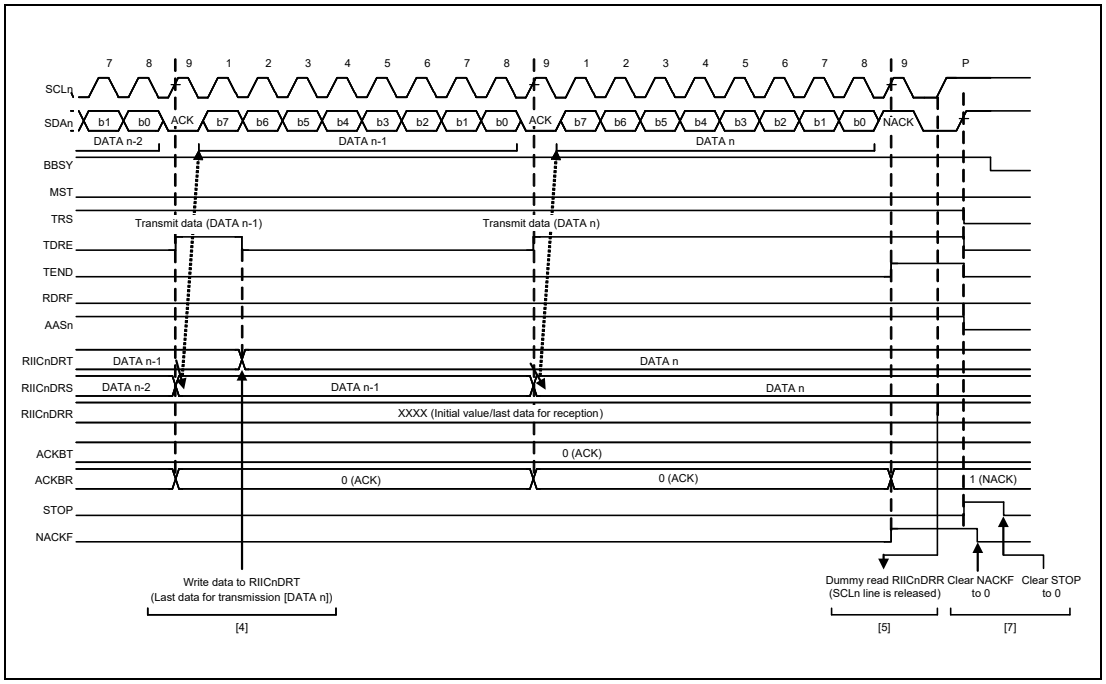

Figure 18.17 Slave Transmit Operation Timing (2)

18.5.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 18.18 shows an example of usage of slave reception and Figure 18.19 and Figure 18.20 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Follow the procedure in Figure 18.5 to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the RIICnSR2.RDRF flag to 1.

(3) After the RIICnSR2.STOP flag is confirmed to be 0 and the RIICnSR2.RDRF flag to be 1, dummy read RIICnDRR (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower eight bits when the 10-bit address format is selected).

(4) When RIICnDRR is read, the RIIC automatically clears the RIICnSR2.RDRF flag to 0. If reading of RIICnDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading RIICnDRR releases the SCL line from being held at the low level.
When the RIICnSR2.STOP flag is 1 and the RIICnSR2.RDRF flag is also 1, read RIICnDRR until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.

(6) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.STOP flag to 0 for the next transfer operation.

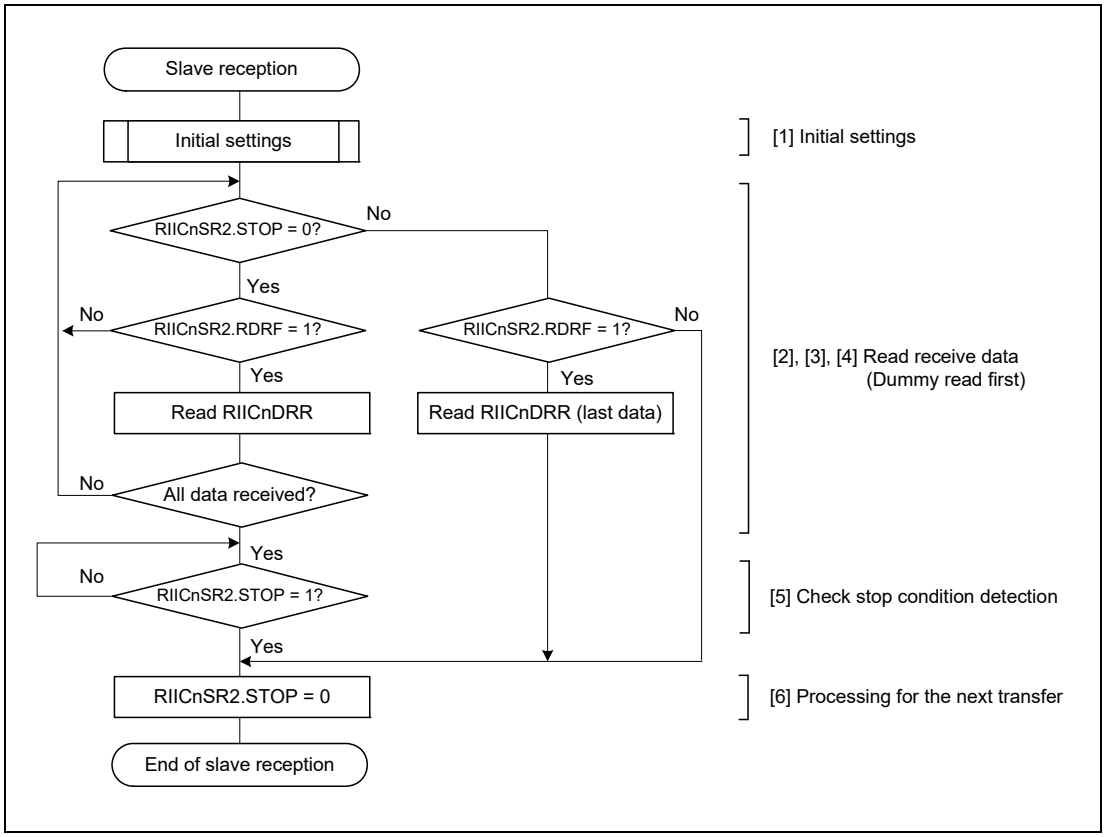

Figure 18.18 Example of Slave Reception Flowchart

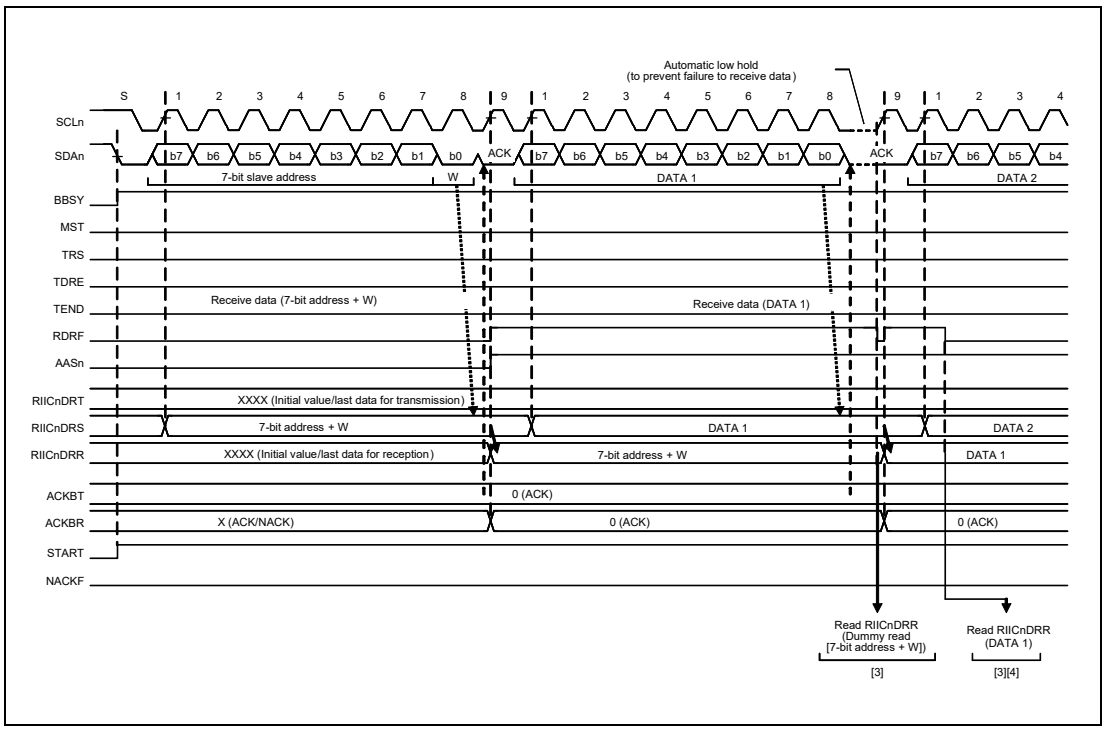

Figure 18.19 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS = 0)

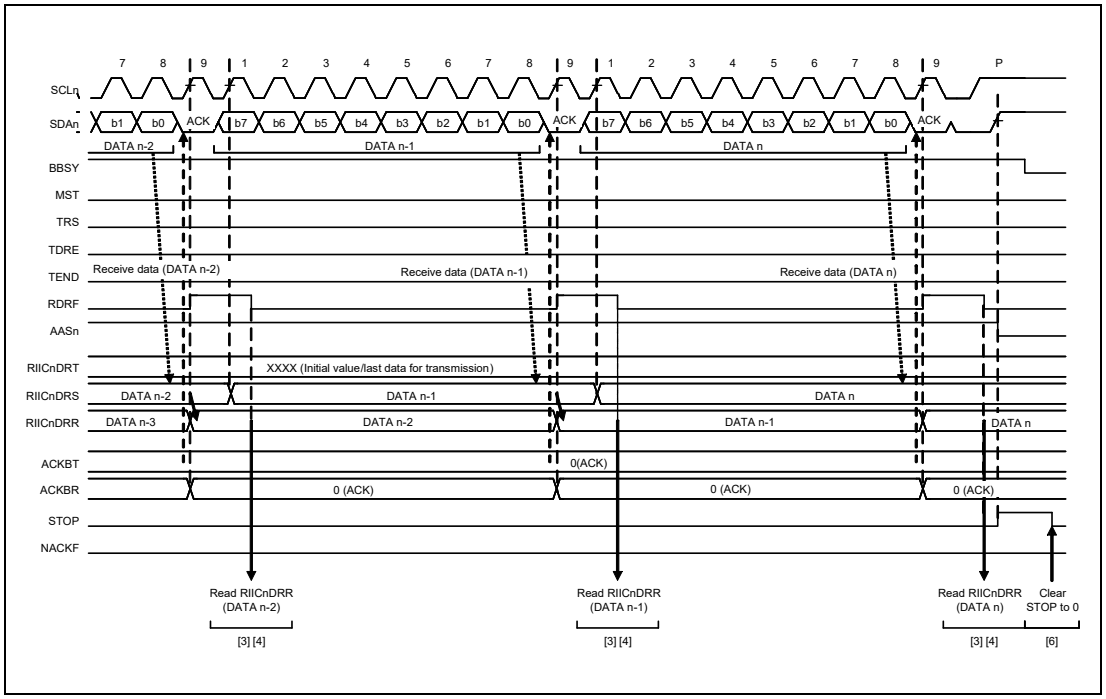

Figure 18.20 Slave Receive Operation Timing (2) (when RDRFS = 0)

18.6 SCL Synchronization Circuit

In generation of the SCL (clock) signal, the RIIC starts counting out the value for width at high level specified in RIICnBRH when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL line, it starts counting out the width at low level period specified in RIICnBRL, and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL (clock) signal is thus generated.

If multiple master devices are connected to the I2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line during communication.

When the RIIC has detected a rising edge on the SCL line and thus started counting out the width at high level specified in RIICnBRH, and the level on the SCL line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in RIICnBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCL line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the RIICnFER.SCLE bit is set to 1.

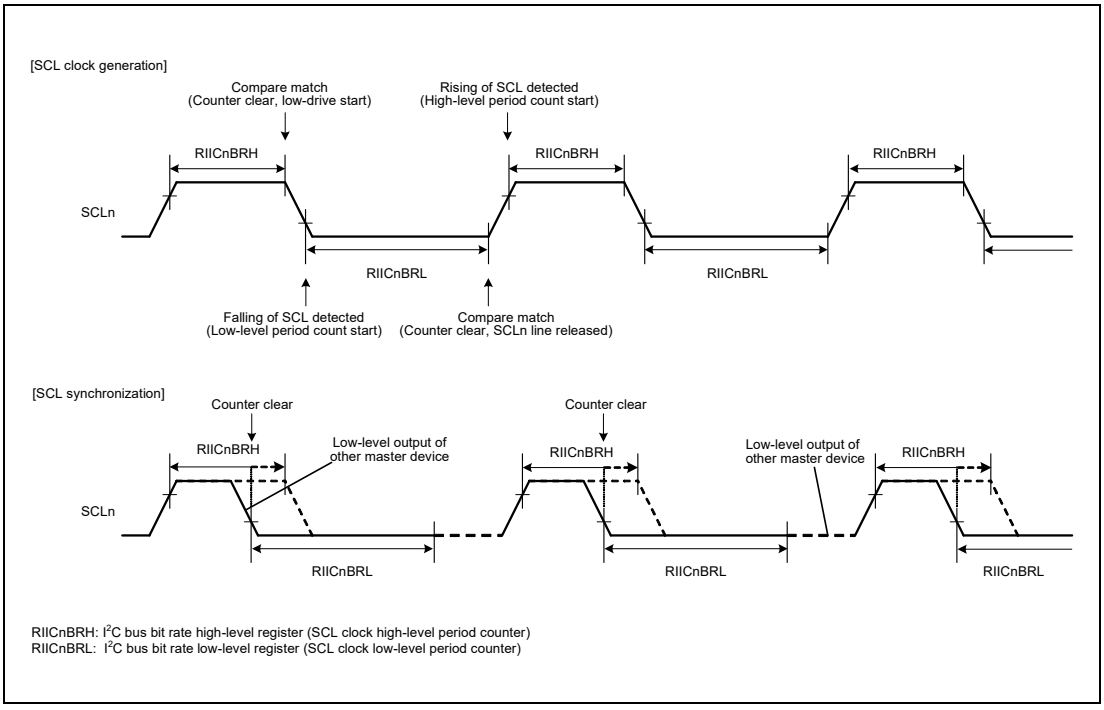

Figure 18.21 Generation and Synchronization of the SCL Signal from the RIIC

18.7 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL (clock) signal is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300-ns (min.) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the RIICnMR2.SDDL[2:0] bits to any value other than 000_B, and disabled by setting the same bits to 000_B.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits in IMCR2 are set to any value other than 000_B), the RIICnMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IICϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in IMCR2. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

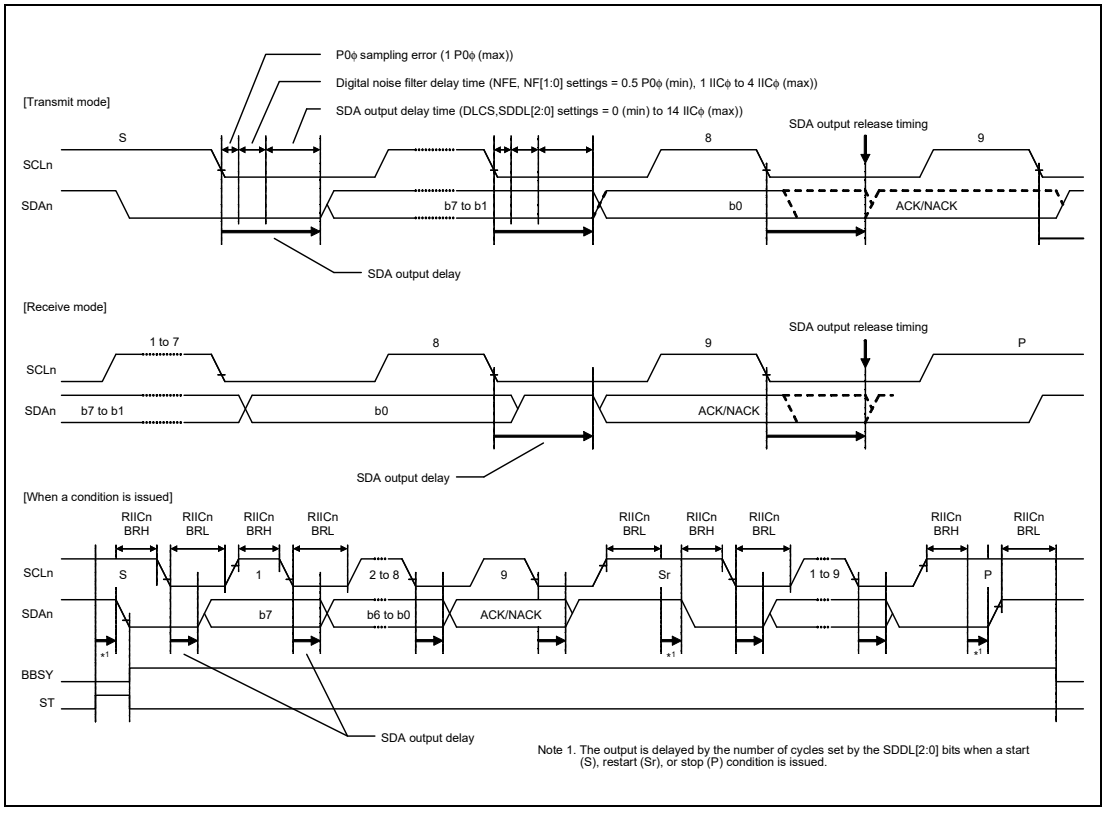

Figure 18.22 SDA Output Delay Facility

18.8 Digital Noise-Filter Circuits

Figure 18.23 is a block diagram of the digital noise-filter circuit. When the NFE bit in the RIICnFER register is set to 1, input to the RIICnSCL and RIICnSDA pins are conveyed to the internal circuitry through digital noise-filter circuits.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the RIICnMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the RIICnSCL pin (or RIICnSDA pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the RIICnMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

Note that if the ratio of the frequencies for P0ϕ and IICϕ is small (when the RIICnMR1.CKS[2:0] bits are set to "000_B"), even necessary signals might be eliminated due to the characteristics of the digital noise filter.

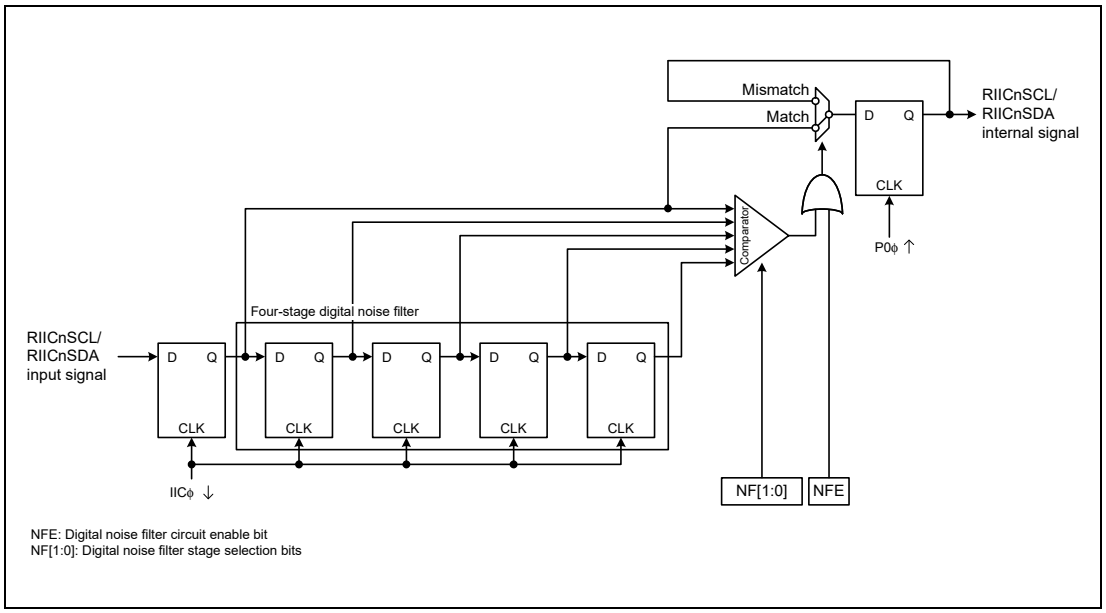

Figure 18.23 Block Diagram of Digital Noise Filter Circuit

18.9 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

18.9.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the RIICnSER.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in RIICnSARy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the corresponding RIICnSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the RIICnSR2.RDRF flag or the RIICnSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (INTRIICRI) or transmit data empty interrupt (INTRIICTI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 18.24 to Figure 18.26 show the AASy flag set timing in three cases.

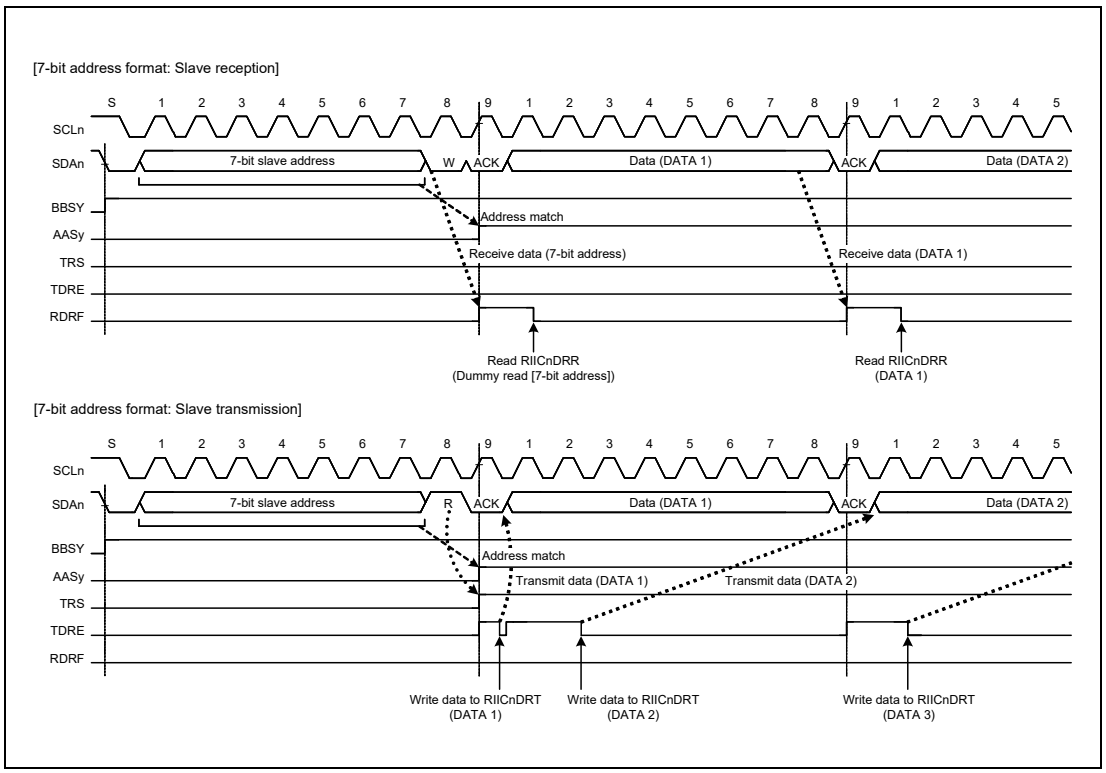

Figure 18.24 AASy Flag Set Timing with 7-Bit Address Format Selected

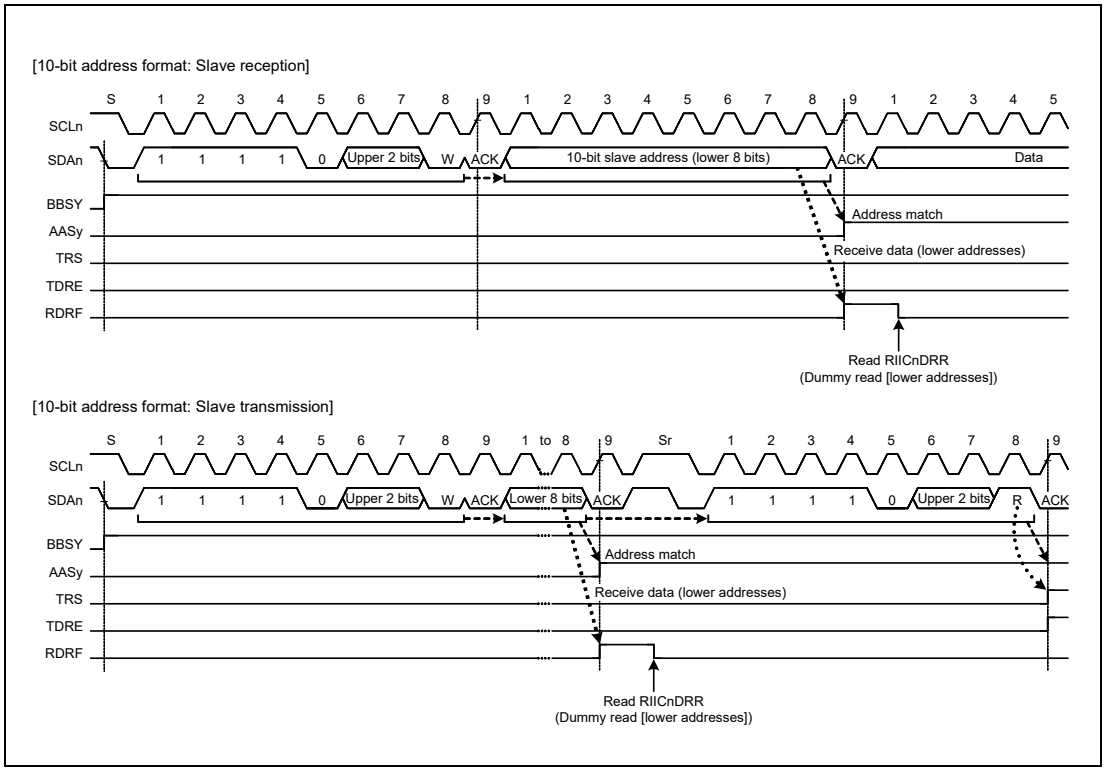

Figure 18.25 AASy Flag Set Timing with 10-Bit Address Format Selected

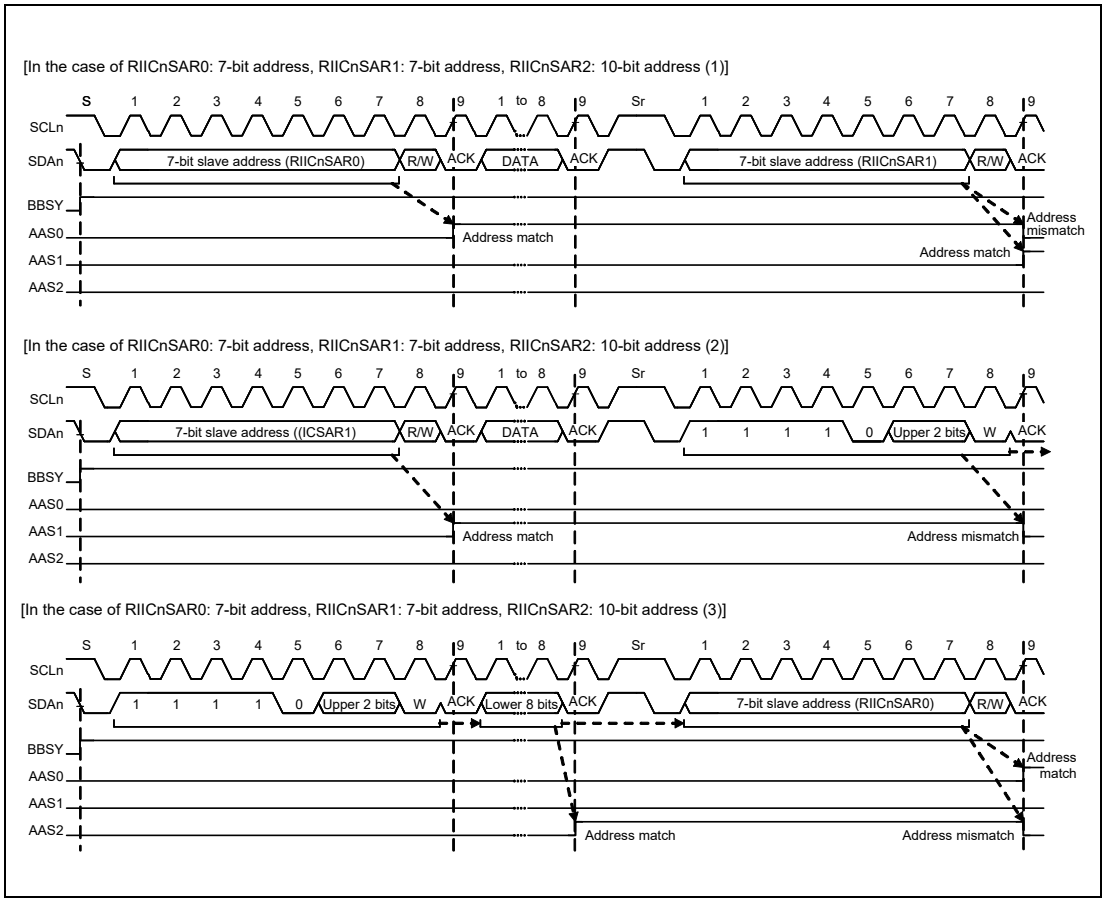

Figure 18.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

18.9.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address (0000 000_B + 0 [W]). This is enabled by setting the RIICnSER.GCE bit to 1.

If the address received after a start or restart condition is issued is 0000 000_B + 1[R] (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the RIICnSR1.GCA flag and the RIICnSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (INTRIICRI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

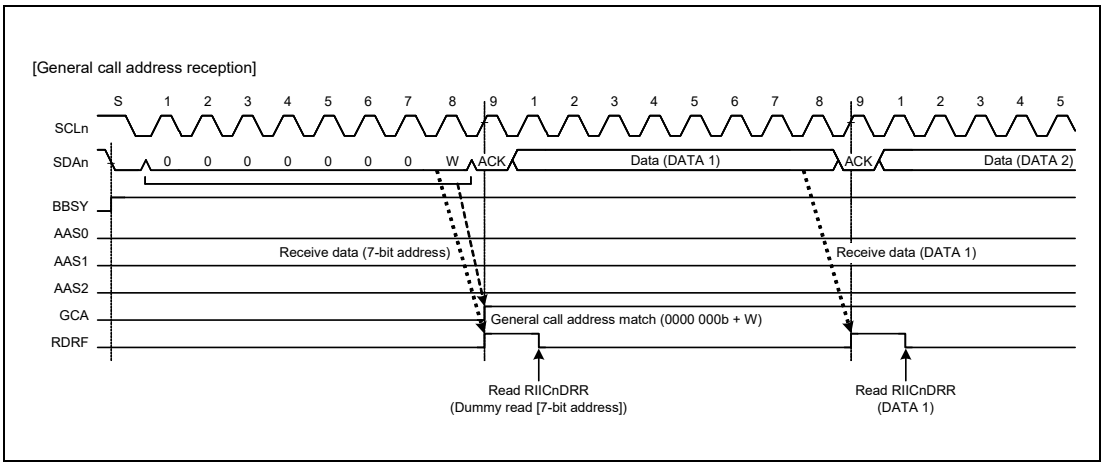

Figure 18.27 Timing of GCA Flag Setting during Reception of General Call Address

18.9.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conformant with the I2C bus specification (Rev. 03). When the RIIC receives 1111 100_B as the first byte after a start condition or restart condition was issued with the RIICnSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the RIICnSR1.DID flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding RIICnSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100_B) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the RIICnSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC clears the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100_B) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details, see I2C Bus Standard from NXP Semiconductors.

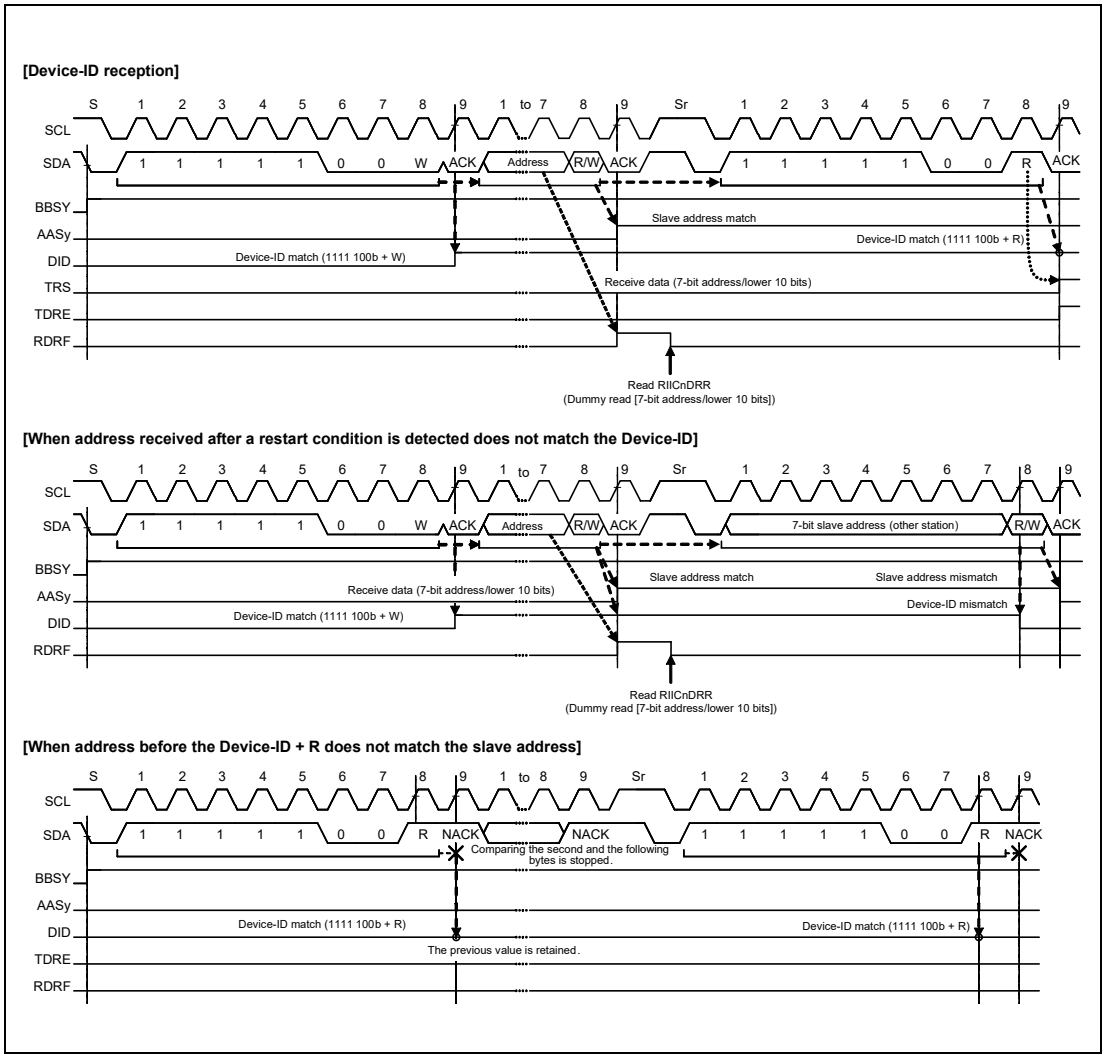

Figure 18.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

18.9.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the RIICnSER.HOAE bit is set to 1 while the RIICnMR3.SMBS bit is 1, the RIIC can detect the host address ($0001\ 000_B$) in slave receive mode (RIICnCR2.MST and TRS bits = 00_B).

When the RIIC detects the host address, the RIICnSR1.HOA flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the RIICnSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (INTRIICRI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address ($0001\ 000_B$) is an Rd bit (R/W# bit = 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

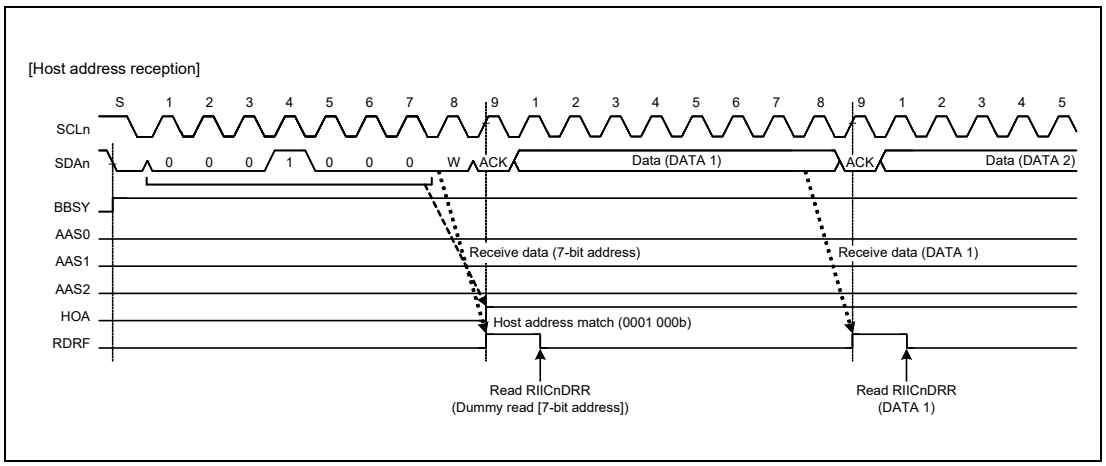

Figure 18.29 HOA Flag Set Timing during Reception of Host Address

18.10 Automatically Low-Hold Function for SCL

18.10.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (RIICnDRS) is empty when data have not been written to the transmit data register (RIICnDRT) with the RIIC in transmission mode (RIICnCR2.TRS bit = 1), the SCL signal is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

<Master transmit mode>

- Low-level interval after a start condition or restart condition is issued
- Low-level interval of one clock cycle between the ninth clock cycle of one transfer and the first clock cycle of the next

<Slave transmit mode>

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

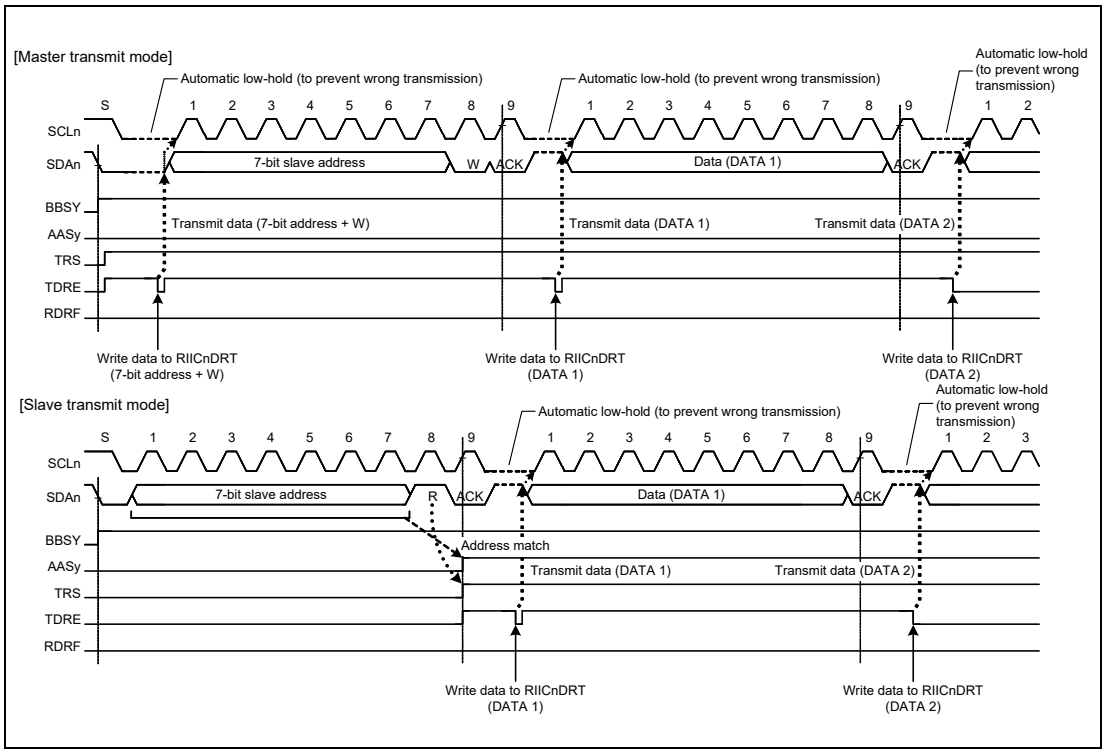

Figure 18.30 Automatic Low-Hold Operation in Transmit Mode

18.10.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (RIICnCR2.TRS bit = 1). This function is enabled when the RIICnFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (RIICnSR2.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (RIICnSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to clear the NACKF flag to 0. In master transmit mode, clear the NACKF flag to 0 after issuing a restart condition or clear the NACKF and STOP flags to 0 after confirming that a stop condition has been issued, and then issue a start condition.

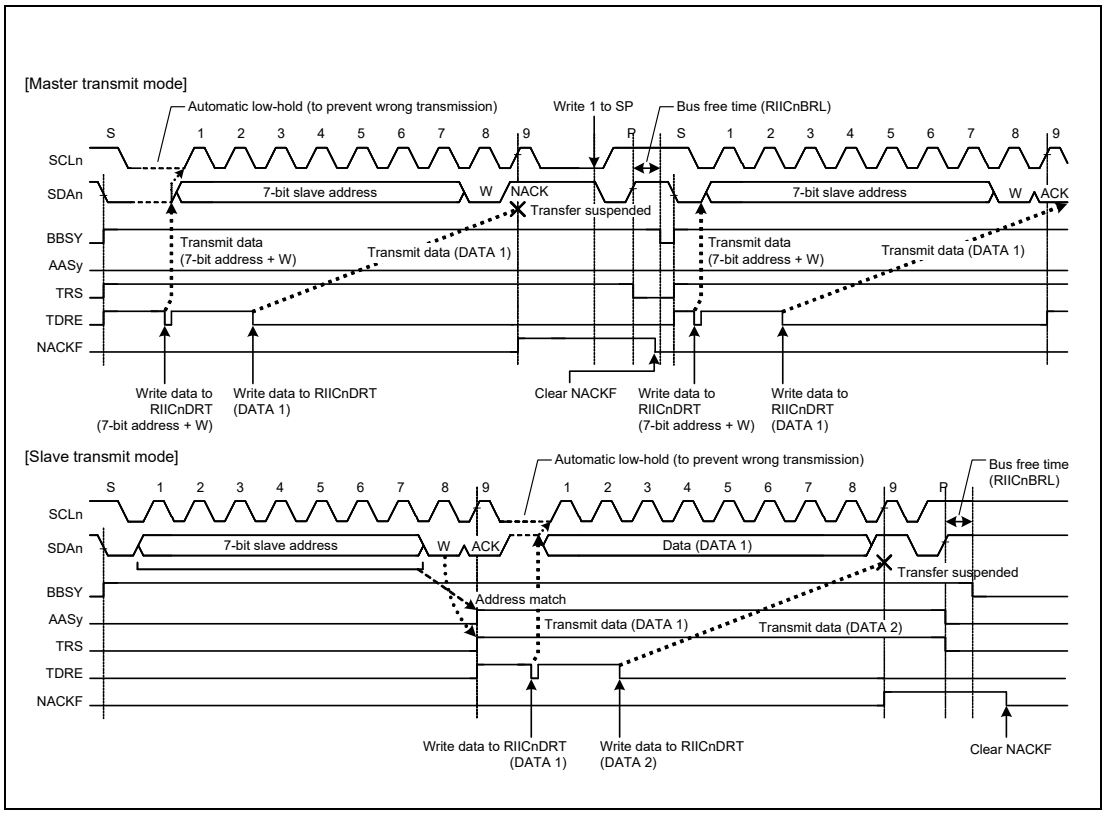

Figure 18.31 Suspension of Data Transfer when NACK is Received (NACKE = 1)

18.10.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (RIICnDRR) read is delayed for a period of one transfer frame or more with receive data full (RIICnSR2.RDRF flag = 1) in receive mode (RIICnCR2.TRS = 0), the RIIC holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCL line low when a mismatch with its own slave address occurs after a stop condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RIICnMR3.WAIT and RDRFS bits.

(1) One-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the RIICnMR3.WAIT bit is set to 1, the RIIC performs one-byte receive operation using the WAIT bit function.
Furthermore, when the RIICnMR3.RDRFS bit is 0, the RIIC automatically sends the RIICnMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from RIICnDRR, which enables bytewise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) One-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RIICnMR3.RDRFS bit is set to 1, the RIIC performs one-byte receive operation using the RDRFS bit function.
When the RIICnSR2.RDRFS bit is set to 1, the RDRF flag (receive data full) in RIICnSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This lowhold is released by writing a value to the RIICnMR3.ACKBT bit, but cannot be released by reading data from RIICnDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

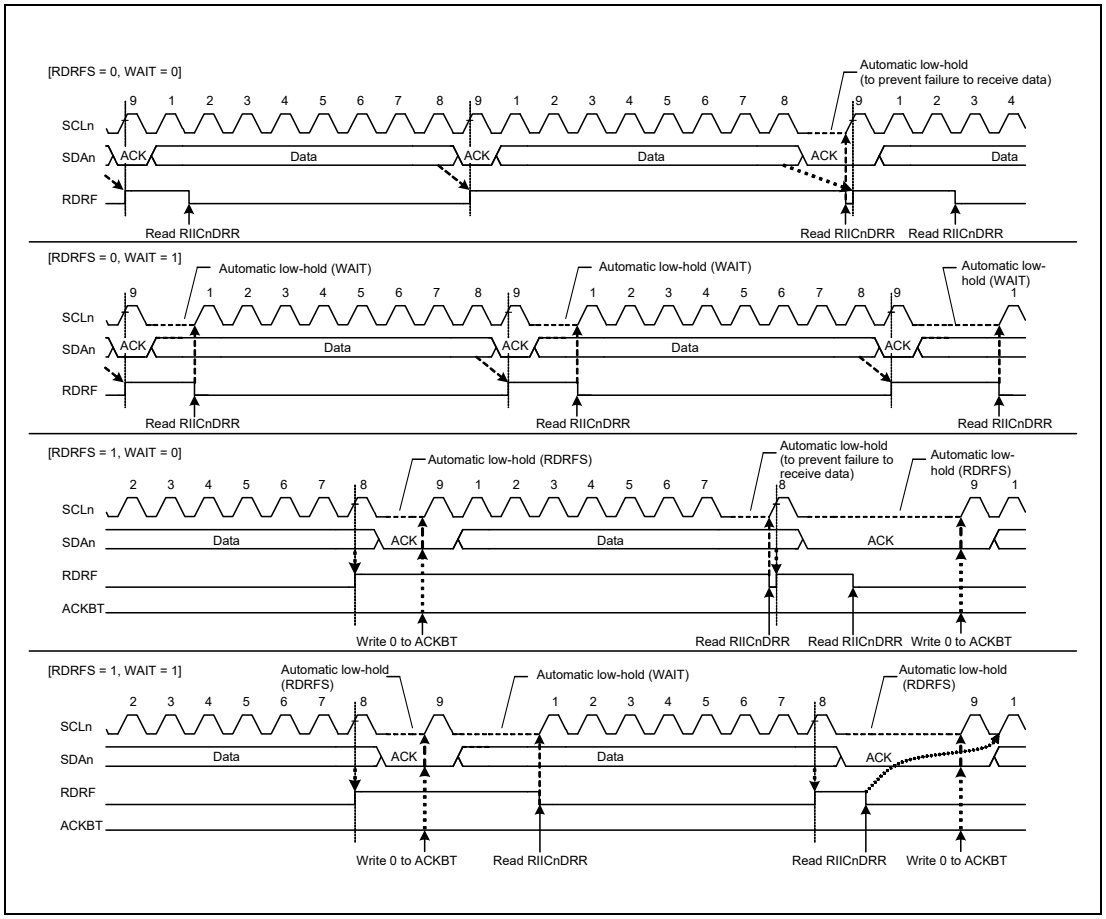

Figure 18.32 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

18.11 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

18.11.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a start condition, the RIIC regards its own issuing of a start condition as an error and considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the RIICnCR2.ST bit to 1 while the bus is busy (RIICnCR2.BBSY flag = 1), the RIIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration, thus preventing a failure of transfer due to issuing of a start condition while transfer is in progress.

When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line, the RIIC loses in arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the RIICnFER.MALE bit is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a start condition was issued by setting the RIICnCR2.ST bit to 1 while the RIICnCR2.BBSY flag was cleared to 0 (erroneous issuing of a start condition)
- Setting of the RIICnCR2.ST bit to 1 (start condition double-issue error) while the RIICnCR2.BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (RIICnCR2.MST and TRS bits = 11_B)

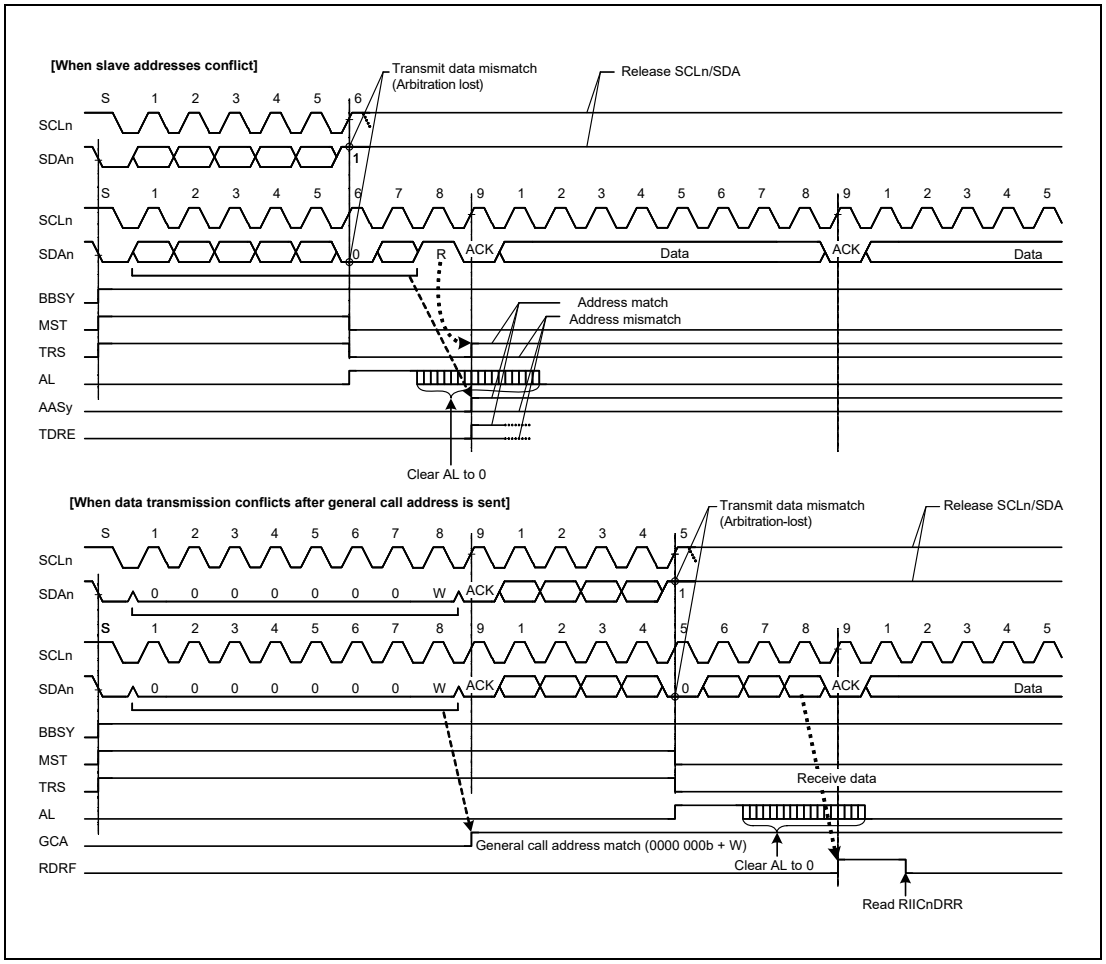

Figure 18.33 Examples of Master Arbitration-Lost Detection (MALE = 1)

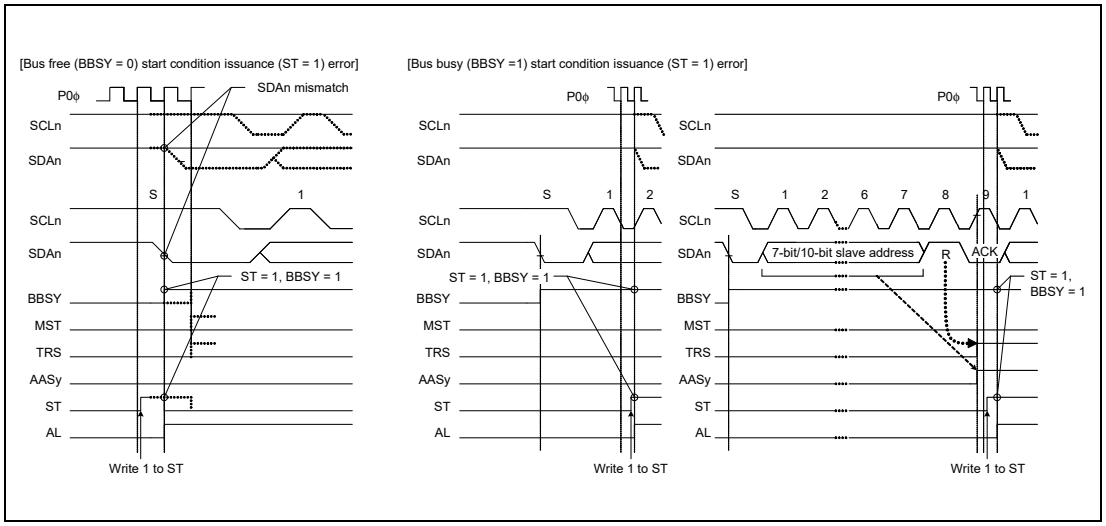

Figure 18.34 Arbitration-Lost when a Start Condition is Issued (MALE = 1)

18.11.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 18.35 shows an example of arbitration-lost detection during transmission of NACK.

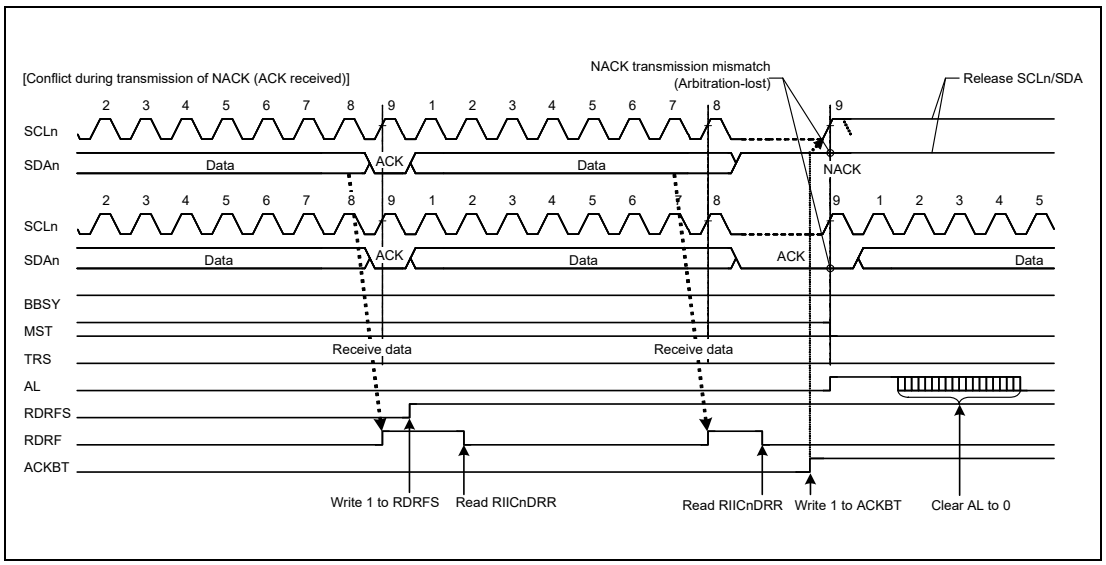

Figure 18.35 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition.

Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as FF_H

transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign address command.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the RIICnFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (RIICnMR3.ACKBT bit = 1)

18.11.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the highimpedance state) and the low level is detected on the SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When it loses slave arbitration, the RIIC enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates

subsequent redundant processing (processing for the transmission of FF_H).

The RIIC detects slave arbitration-lost when the following condition is met with the RIICnFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

When transmit data excluding acknowledge (internal SDA output level) does not match the SDA line in slave transmit mode (RIICnCR2.MST and TRS bits = 01_B)

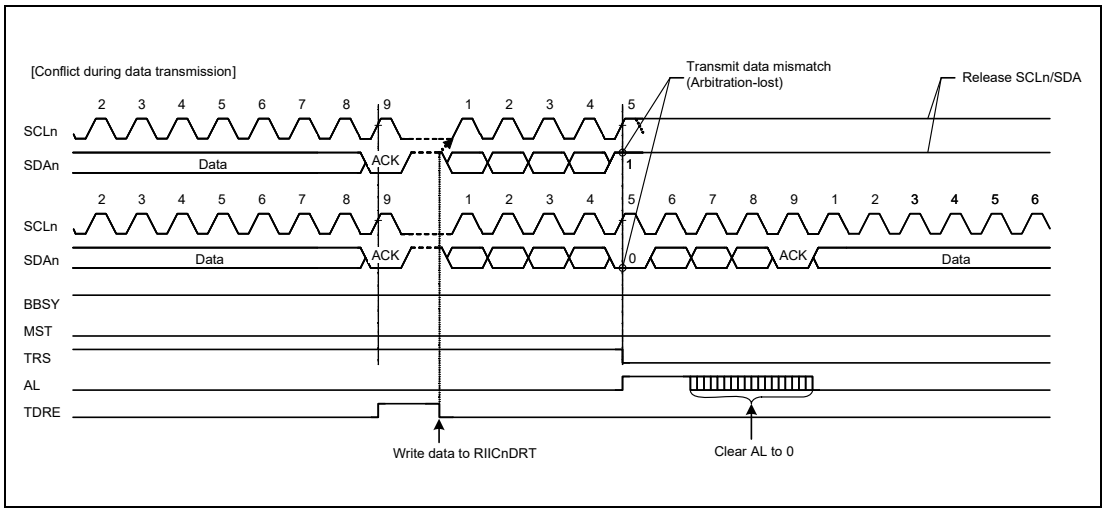

Figure 18.36 Example of Slave Arbitration-Lost Detection (SALE = 1)

18.12 Start Condition/Restart Condition/Stop Condition Issuing Function

18.12.1 Issuing a Start Condition

The RIIC issues a start condition when the RIICnCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the RIICnCR2.BBSY flag is 0 (bus free). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.

A start condition is issued in the following sequence.

[Start condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the start condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

18.12.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RIICnCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition issuance request is made and the RIIC issues a restart condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A restart condition is issued in the following sequence.

[Restart condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRL and the restart condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the restart condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

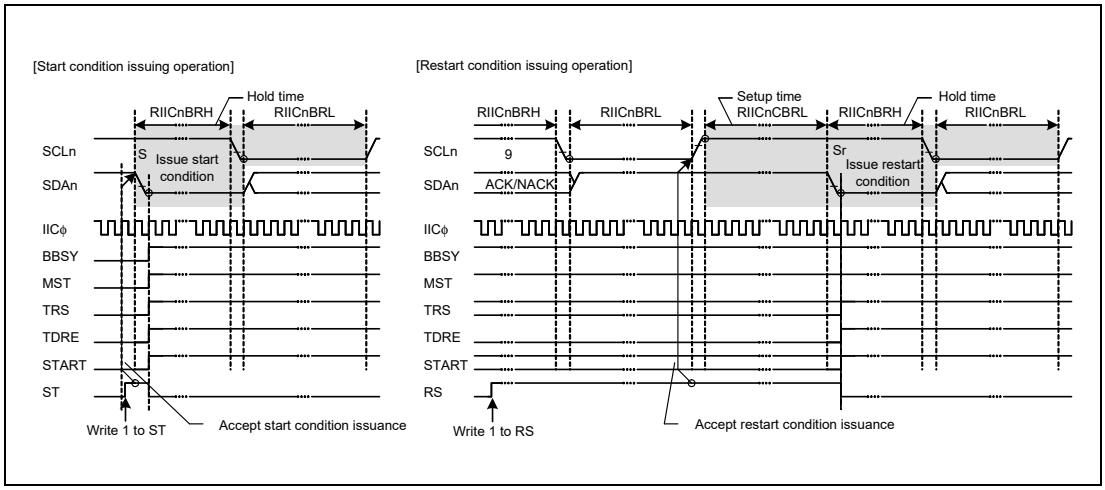

Figure 18.37 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

18.12.3 Issuing a Stop Condition

The RIIC issues a stop condition when the RIICnCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRH and the stop condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in RIICnBRL and the bus free time.
- Clear the BBSY flag to 0 (to release the bus mastership).

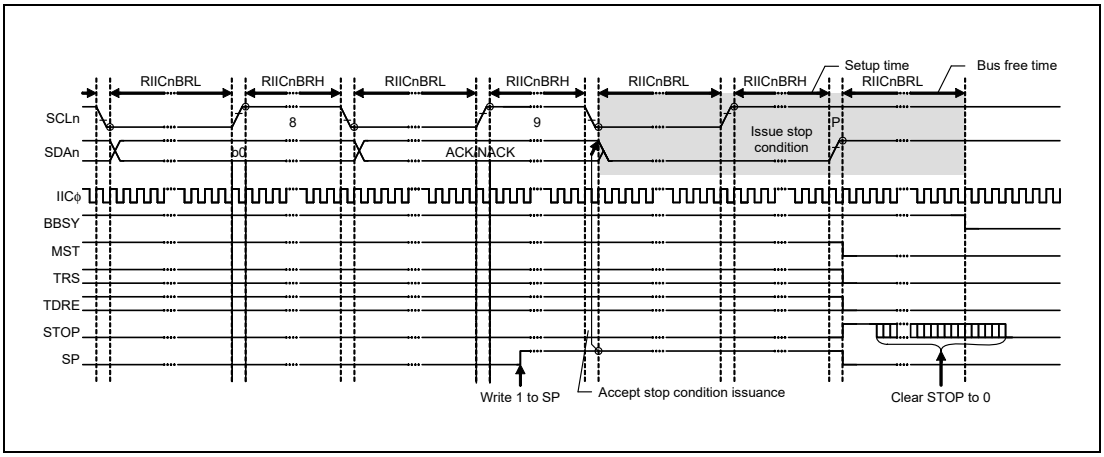

Figure 18.38 Stop Condition Issue Timing (SP Bit)

18.13 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I2C bus might hang with a fixed level on the SCL line and/or SDA line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, and the RIIC/internal reset function.

By checking the RIICnCR1.SCLO, SDAO, SCLI, and SDAI bits, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL or SDA lines.

18.13.1 Timeout Function

The RIIC has the timeout function to detect an abnormality that the SCL line is held for a certain period of time. The RIIC can detect an abnormal bus state by monitoring that the SCL line is held low or high for a predetermined time.

The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, the RIIC can detect the timeout and report the bus abnormality.

This timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state in which the SCL line is held low or high in the following cases.

<1> The bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1).

<2> The bus is busy (RIICnCR2.BBSY = 1) and the RIIC's own slave address matches (RIICnSR1 is not 00_H) in slave mode (RIICnCR2.MST = 0).

<3> The bus is free (RIICnCR2.BBSY = 0) and issuing of a start condition is being requested (RIICnCR2.ST = 1).

The internal counter of the timeout function works using the internal reference clock (IICϕ) set by the RIICnMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (RIICnMR2.TMOS bit = 0) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL line level (low/high or both levels) during which this counter is activated can be selected by the setting of the RIICnMR2.TMOH and TMOL bits. If both TMOL and TMOH bits are cleared to 0, the internal counter does not work.

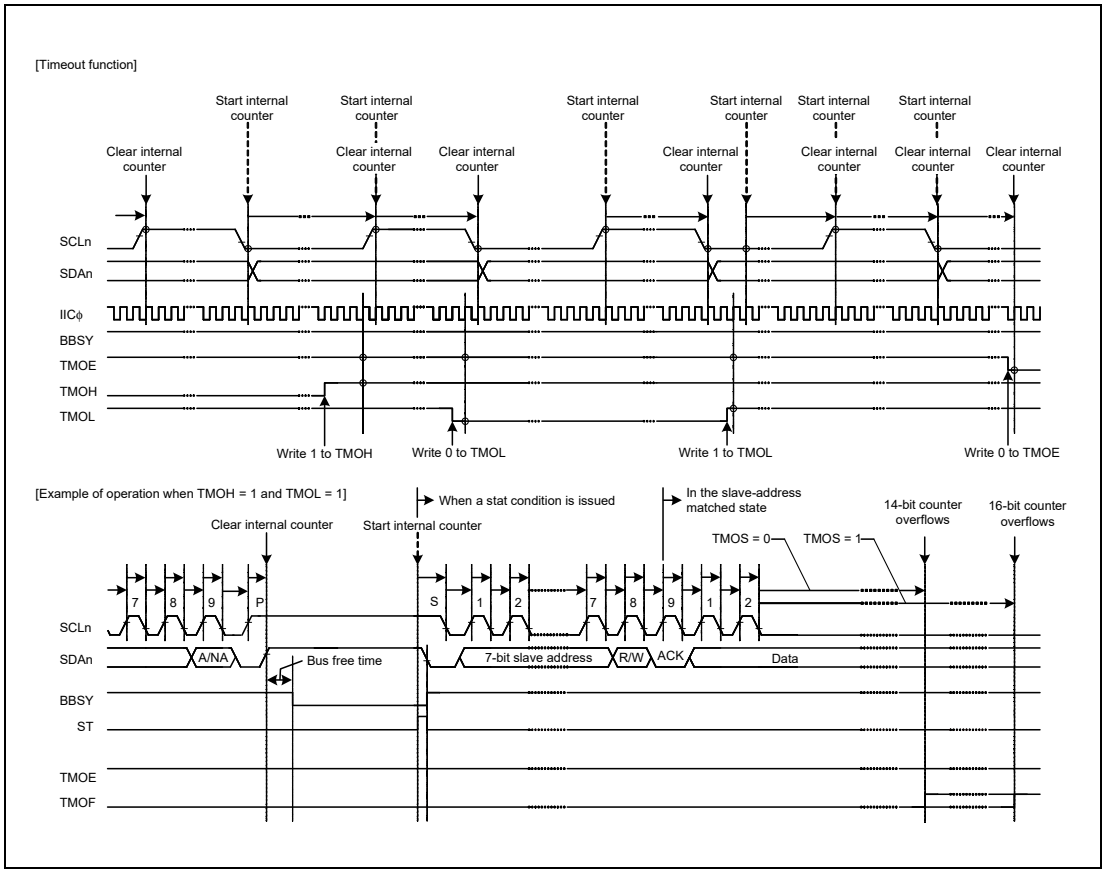

Figure 18.39 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

18.13.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL (clock) cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL (clock) signal as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the RIICnCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the RIICnMR1.CKS[2:0] bits, and of the RIICnBRH and RIICnBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically cleared to 0. Therefore, further extra clock cycles can be output consecutively by the software program writing 1 to the CLO bit after having read CLO = 0.

When the RIIC module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL (clock) signal can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the RIICnCR1.SDAI bit. After confirming release of the SDA line by the slave device, complete communications by reissuing the stop condition.

Use this facility with the RIICnFER.MALE bit (master arbitration-lost detection disabled) cleared to 0. If the MALE bit is set to 1 (master arbitration-lost detection enabled), arbitration is lost when the value of the RIICnCR1.SDAO bit does not match the state of the SDA line, so take care on this point.

[Output conditions for using the RIICnCR1.CLO bit]

- When the bus is free (RIICnCR2.BBSY flag = 0) or in master mode (RIICnCR2.MST bit = 1 and BBSY flag = 1)
- When the communication device does not hold the SCL line low

Figure 18.40 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

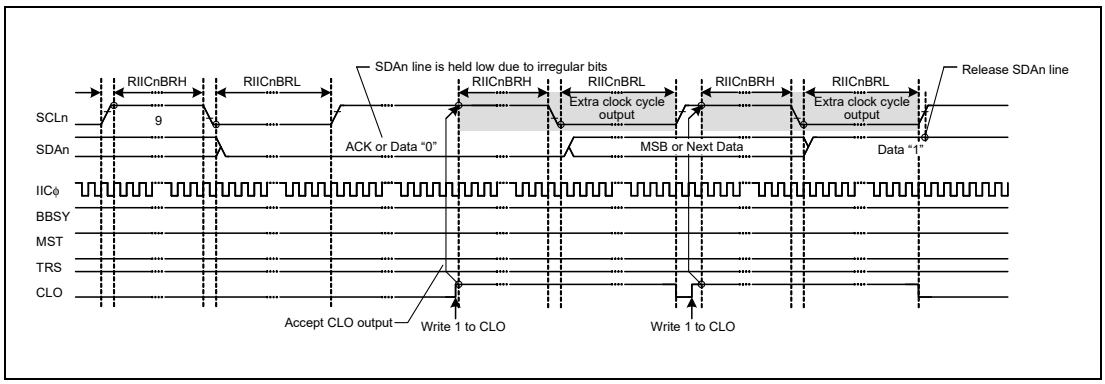

Figure 18.40 Extra SCL Clock Cycle Output Function (CLO Bit)

18.13.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the RIICnCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings.

After issuing a reset, be sure to clear the RIICnCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCL and SDA pins to the high impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (RIICnCR1.ICE and IICRST bits = 01_B).

For a detailed description of the RIIC and internal resets, see Section 18.15, Reset Function of RIIC.

18.14 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the RIICnMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the RIICnMR1.CKS[2:0] bits, RIICnCBRH, and RIICnBRL. In addition, determine the values of the RIICnMR2.DLCS bit and the RIICnMR2.SDDL[2:0] bits to meet the data hold time specification of 300 ns or more. If the RIIC is used only as a slave device, the transfer rate setting is not necessary. When the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the RIICnBRL needs to be set to a value equal to or longer than the data setup time (250 ns).

For the SMBus device default address ($1100\ 001_B$), use one of the slave address registers L0 to L2 (RIICnSAR0, RIICnSAR1, and RIICnSAR2), and set the corresponding RIICnSARy.FSy bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the RIICnFER.SALE bit to 1 to enable the slave arbitration lost detection function.

18.14.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:\ SEXT}$) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

  To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the internal timer using a start condition detection interrupt (INTRIICSTI) and stop condition detection interrupt (INTRIICSPI) of the RIIC. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:\ SEXT}$: 25 ms (max.) of the SMBus standard.
  If the time measured with the internal timer exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus standard, the slave device must release the bus by writing 1 to the RIICnCR1.IICRST bit to issue an internal reset of the RIIC. When an internal reset is issued, the RIIC stops driving the bus for the SCL pin and SDA pin and make the SCL/SDA pin outputs high impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:\ MEXT}$) must be measured for master devices in SMBus communication.

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the internal timer using a start condition detection interrupt (INTRIICSTI), stop condition detection interrupt (INTRIICSPI), and transmit end interrupt (INTRIICTEI) or receive data full interrupt (INTRIICRI) of the RIIC. The measured timeout period must be within the total clock low-level extended period [master device] $T_{LOW:\ MEXT}$: 10 ms (max.) of the SMBus standard, and the total of all $T_{LOW:\ MEXT}$ from start condition to stop condition must be within $T_{LOW:\ SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SMBCLK clock cycle), monitor theRIICnSR2. TEND flag in master transmit mode (master transmitter) and the RIICnSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the RIICnMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SMBCLK clock cycle.

If the period measured with the internal timer exceeds the total clock low-level extended period [master device] $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to RIICnDRT).

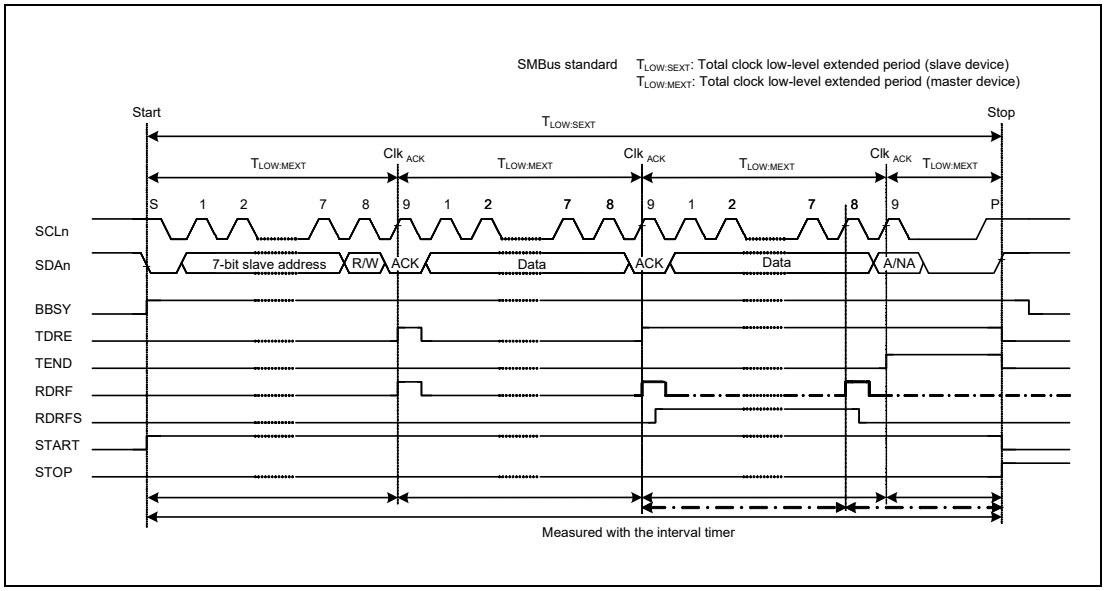

Figure 18.41 SMBus Timeout Measurement

18.14.2 SMBus Host Notification Protocol/Notify ARP Master

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of (or request the SMBus host for) its own slave address or to request its own slave address from the SMBus host.

For this LSI to operate as an SMBus host (or ARP master), the host address ($0001\ 000_B$) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the RIICnMR3.SMBS bit and the RIICnSER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

18.15 Reset Function of RIIC

The RIIC has chip reset, RIIC reset, and internal reset functions. Table 18.24 lists the scope of each reset and reset conditions.

Table 18.24 RIIC Reset Functions (1/2)

Register		RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start Condition/ Restart Condition Detection	Stop Condition Detection

Note 1. When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.
When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.

19. Serial Sound Interface

The serial sound interface is a module designed to send or receive audio data interface with various devices offering I^2S bus compatibility. It also provides additional modes for other common formats, as well as support for multi-channel mode.

19.1 Features

- Number of channels: Four channels
- Operating mode: Non-compressed mode
  The non-compressed mode supports serial audio streams divided by channels.
- Serves as both a transmitter and a receiver
  Channels 0, 1, and 3 support full-duplex communications.
- Capable of using serial bus format
- Asynchronous transfer takes place between the data buffer and the shift register.
- It is possible to select a dividing ratio for the clock used by the serial bus interface.
- It is possible to control data transmission or reception with DMA transfer and interrupt requests.
  A path is also provided for direct data transfer between this module and the SCUX module.
- Selects the oversampling clock input from among the following pins:
  —AUDIO_CLK (1 to 50 MHz)
  —AUDIO_X1, AUDIO_X2 (when connecting a crystal resonator: 10 to 50 MHz, when used to input external clock: 1 to 50 MHz)
- Includes 8-stage FIFO buffers in transmitter and receiver
- Supports multi-channel mode (TDM mode) in which the SSIWS signal is high only for system word 1 period.
- Supports WS continue mode in which the SSIWS signal is not stopped.
- An interrupt is used to notify the CPU of a change of sampling frequency during transfer.

Figure 19.1 shows a block diagram of this module.

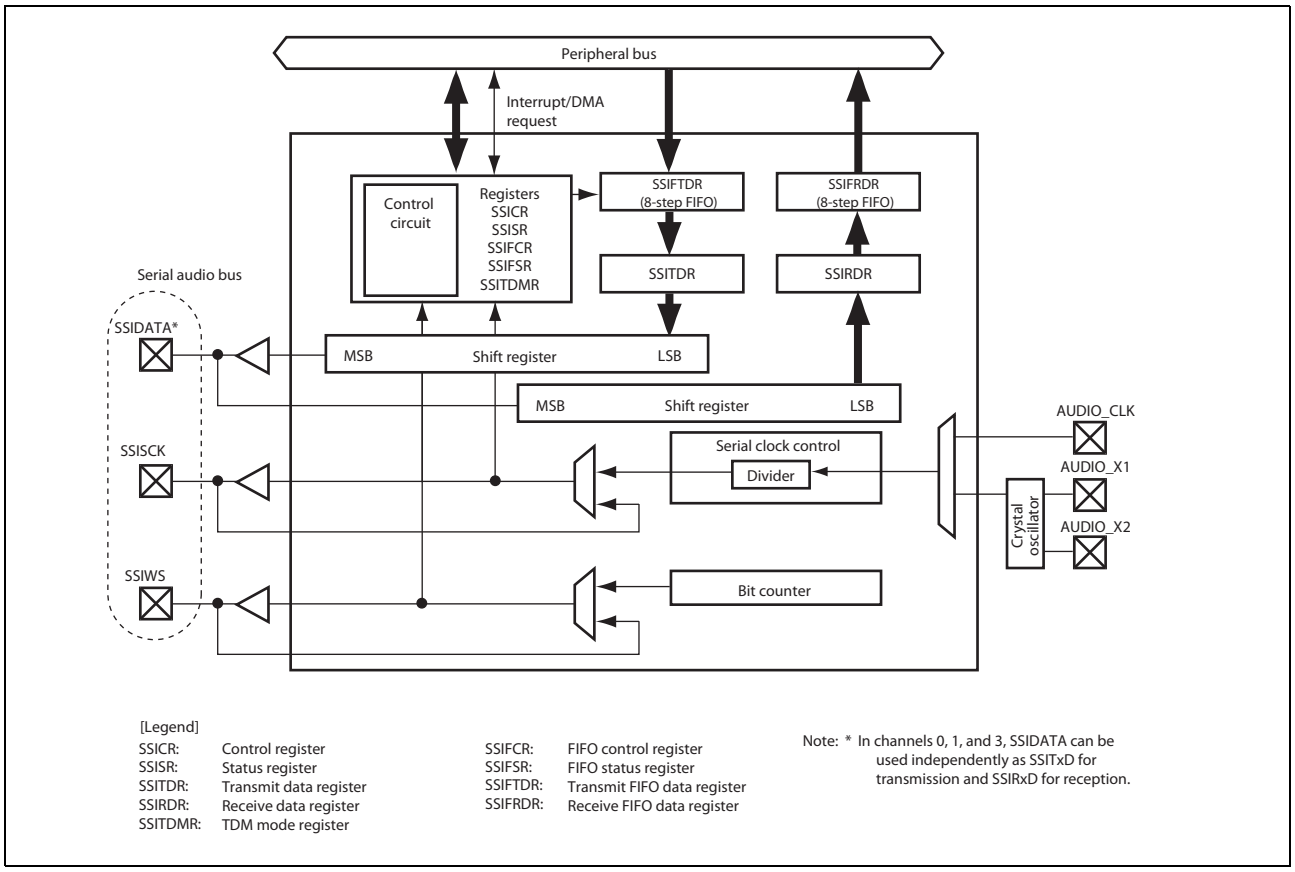

Figure 19.1 Block Diagram of Serial Sound Interface

19.2 Input/Output Pins

Table 19.1 shows the pin assignments relating to this module.

Table 19.1 Pin Assignments

Channel	Pin Name	I/O	Description
0, 1, 3	SSISCK0*1*3, SSISCK1*1*3, SSISCK3*1*3	I/O	Serial bit clock
	SSIWS0*1*3, SSIWS1*1*3, SSIWS3*1*3	I/O	Word selection
	SSITxD0, SSITxD1, SSITxD3	Output	Serial data output
	SSIRxD0*1, SSIRxD1*1, SSIRxD3*1	Input	Serial data input
2	SSISCK2*1*3	I/O	Serial bit clock
	SSIWS2*1*3	I/O	Word selection
	SSIDATA2*1	I/O	Serial data input/output
Common	AUDIO_CLK*2	Input	External clock for audio (input oversampling clock)
	AUDIO_X1	Input	Crystal resonator/external clock for audio (input oversampling clock)
	AUDIO_X2	Output	

Note 1. In slave mode, whether or not to use the noise canceler in the input route can be selected. For details, refer to section 41.3.15, Serial Sound Interface Noise Canceler Control Register (SNCR), under section 41, Ports.

Note 2. When the SSInCKS bit (n = 0 to 3) is set to 1, the MLB_CLK pin is used as the AUDIO_CLK pin. For details, refer to section 37.3.70, SSI Pin Mode Register (SSIPMD_CIM) and section 37.4.4, Pin Connection Specifications of SSIF.

Note 3. Each of SSIF1 to SSIF3 can use SSISCK0 and SSIWS0 of SSIF0 as its own SSISCK and SSIWS. For details, refer to section 37.3.70, SSI Pin Mode Register (SSIPMD_CIM) and section 37.4.4, Pin Connection Specifications of SSIF. When SSIF1 to SSIF3 uses SSIF0 as the master, the noise canceler function cannot be used.

19.3 Register Description

Table 19.2 lists the register configuration. Note that explanation in the text does not refer to the channels.

Table 19.2 Register Configuration

Channel	Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
0	Control register 0	SSICR_0	R/W	H'00000000	H'E820B000	32
	Status register 0	SSISR_0	R/W*1	H'02000013	H'E820B004	32
	FIFO control register 0	SSIFCR_0	R/W	H'00000000	H'E820B010	32

	FIFO status register 1	SSIFSR_1	R/(W)*2	H'00010000	H'E820B814	32
	Transmit FIFO data register 1	SSIFTDR_1	W	Undefined	H'E820B818	32
	Receive FIFO data register 1	SSIFRDR_1	R	Undefined	H'E820B81C	32
	TDM mode register 1	SSITDMR_1	R/W	H'00000000	H'E820B820	32
	FC control register 1	SSIFCCR_1	R/W	H'00000000	H'E820B824	32
	FC mode register 1	SSIFCMR_1	R/W	H'00000000	H'E820B828	32
	FC status register 1	SSIFCSR_1	R/(W)*3	H'00000000	H'E820B82C	32
2	Control register 2	SSICR_2	R/W	H'00000000	H'E820C000	32
	Status register 2	SSISR_2	R/W*1	H'02000013	H'E820C004	32
	FIFO control register 2	SSIFCR_2	R/W	H'00000000	H'E820C010	32
	FIFO status register 2	SSIFSR_2	R/(W)*2	H'00010000	H'E820C014	32
	Transmit FIFO data register 2	SSIFTDR_2	W	Undefined	H'E820C018	32
	Receive FIFO data register 2	SSIFRDR_2	R	Undefined	H'E820C01C	32
	TDM mode register 2	SSITDMR_2	R/W	H'00000000	H'E820C020	32
	FC control register 2	SSIFCCR_2	R/W	H'00000000	H'E820C024	32
	FC mode register 2	SSIFCMR_2	R/W	H'00000000	H'E820C028	32
	FC status register 2	SSIFCSR_2	R/(W)*3	H'00000000	H'E820C02C	32
3	Control register 3	SSICR_3	R/W	H'00000000	H'E820C800	32
	Status register 3	SSISR_3	R/W*1	H'02000013	H'E820C804	32
	FIFO control register 3	SSIFCR_3	R/W	H'00000000	H'E820C810	32
	FIFO status register 3	SSIFSR_3	R/(W)*2	H'00010000	H'E820C814	32
	Transmit FIFO data register 3	SSIFTDR_3	W	Undefined	H'E820C818	32
	Receive FIFO data register 3	SSIFRDR_3	R	Undefined	H'E820C81C	32
	TDM mode register 3	SSITDMR_3	R/W	H'00000000	H'E820C820	32
	FC control register 3	SSIFCCR_3	R/W	H'00000000	H'E820C824	32
	FC mode register 3	SSIFCMR_3	R/W	H'00000000	H'E820C828	32
	FC status register 3	SSIFCSR_3	R/(W)*3	H'00000000	H'E820C82C	32

Note 1. Although bits 29 to 26 in these registers can be read from or written to, bits other than these are read-only. For details, refer to section 19.3.2, Status Register (SSISR).

Note 2. To bits 16 and 0 in these registers, only 0 can be written to clear the flags. Other bits are read-only. For details, refer to section 19.3.6, FIFO Status Register (SSIFSR).
Note 3. To bit 24 in these registers, only 0 can be written to clear the flag. Other bits are read-only. For details, refer to section 19.3.12, FC Status Register (SSIFCSR).

19.3.1 Control Register (SSICR)

SSICR is a 32-bit readable/writable register that controls the IRQ, selects the polarity status, and sets operating mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	CKS	TUIEN	TOIEN	RUIEN	ROIEN	IIEN	-	CHNL[1:0]		DWL[2:0]			SWL[2:0]

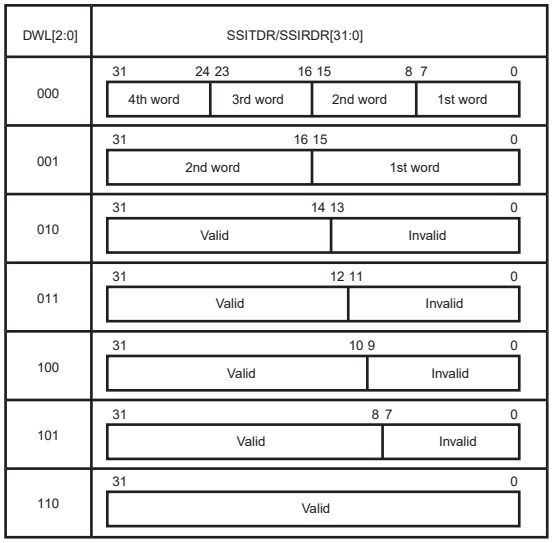
Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved The read value is undefined. The write value should always be 0.
30	CKS	0	R/W	Oversampling Clock Select Selects the clock source for oversampling. 0: AUDIO_X1 input 1: AUDIO_CLK input
29	TUIEN	0	R/W	Transmit Underflow Interrupt Enable 0: Disables an underflow interrupt. 1: Enables an underflow interrupt.
28	TOIEN	0	R/W	Transmit Overflow Interrupt Enable 0: Disables an overflow interrupt. 1: Enables an overflow interrupt.
27	RUIEN	0	R/W	Receive Underflow Interrupt Enable 0: Disables an underflow interrupt. 1: Enables an underflow interrupt.
26	ROIEN	0	R/W	Receive Overflow Interrupt Enable 0: Disables an overflow interrupt. 1: Enables an overflow interrupt.
25	IIEN	0	R/W	Idle Mode Interrupt Enable 0: Disables an idle mode interrupt. 1: Enables an idle mode interrupt.
24	—	0	R	Reserved The read value is undefined. The write value should always be 0.
23, 22	CHNL[1:0]	00	R/W	Channels [When TDM = 0] These bits show the number of channels in each system word. 00: Having one channel per system word 01: Having two channels per system word 10: Having three channels per system word 11: Having four channels per system word [When TDM = 1] These bits show the number of system words in each TDM frame. 00: Setting prohibited 01: Having four system words per TDM frame 10: Having six system words per TDM frame 11: Having eight system words per TDM frame

Bit	Bit Name	Initial Value	R/W	Description
21 to 19	DWL[2:0]	000	R/W	Data Word Length These bits indicate the number of bits in a data word. 000: 8 bits 001: 16 bits 010: 18 bits 011: 20 bits 100: 22 bits 101: 24 bits 110: 32 bits 111: Setting prohibited
18 to 16	SWL[2:0]	000	R/W	System Word Length These bits indicate the number of bits in a system word. 000: 8 bits 001: 16 bits 010: 24 bits 011: 32 bits 100: 48 bits 101: 64 bits 110: 128 bits 111: 256 bits
15	SCKD	0	R/W	Serial Bit Clock Direction 0: Serial bit clock is input, slave mode. 1: Serial bit clock is output, master mode. Note: Only the following settings are allowed: (SCKD, SWSD) = (0, 0) or (1, 1). Other settings are prohibited.
14	SWSD	0	R/W	Serial WS Direction 0: Serial word select is input, slave mode. 1: Serial word select is output, master mode. Note: Only the following settings are allowed: (SCKD, SWSD) = (0,0) or (1,1). Other settings are prohibited.
13	SCKP	0	R/W	Serial Bit Clock Polarity 0: SSIWS and SSIDATA change at the SSISCK falling edge (sampled at the SCK rising edge). 1: SSIWS and SSIDATA change at the SSISCK rising edge (sampled at the SCK falling edge).

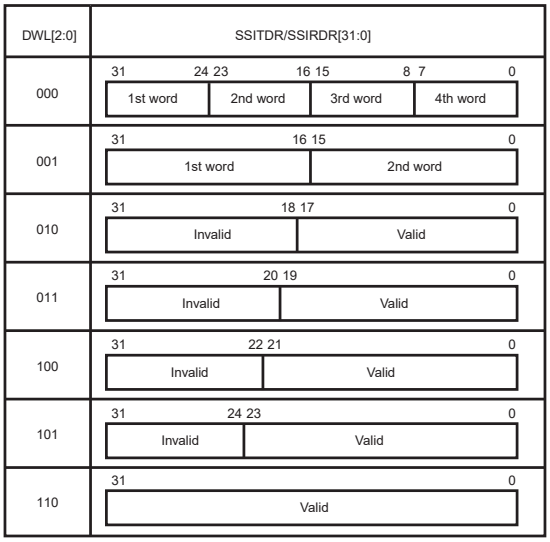
	SCKP =0	SCKP = 1
SSIDATA input sampling timing at the time of reception	SSISCK rising edge	SSISCK falling edge
SSIDATA output change timing at the time of transmission	SSISCK falling edge	SSISCK rising edge
SSIWS input sampling timing at the time of slave mode (SWSD = 0)	SSISCK rising edge	SSISCK falling edge
SSIWS output change timing at the time of master mode (SWSD = 1)	SSISCK falling edge	SSISCK rising edge

12	SWSP	0	R/W	Serial WS Polarity [When TDM = 0] 0: SSIWS is low for the 1st channel, high for the 2nd channel. 1: SSIWS is high for the 1st channel, low for the 2nd channel. [When TDM = 1] 0: SSIWS is high only for system word 1 period, low for other periods. 1: Setting prohibited
11	SPDP	0	R/W	Serial Padding Polarity This bit is used to specify the active sense of padding bits. It is also used to specify the logical value to be output from the SSITxD pin when the MUEN bit is set to 0 with transfer disabled in WS continue mode. 0: Padding bits are low. 1: Padding bits are high.

Bit	Bit Name	Initial Value	R/W	Description
10	SDTA	0	R/W	Serial Data Alignment 0: Transmitting and receiving in the order of serial data and padding bits 1: Transmitting and receiving in the order of padding bits and serial data
9	PDTA	0	R/W	Parallel Data Alignment When the data word length is 32 bits, this configuration field has no meaning. This bit applies to SSIRDR in receive mode and SSITDR in transmit mode. When data word length is 8 or 16 bits: 0: The lower bits of parallel data (SSITDR, SSIRDR) are transferred prior to the upper bits. 1: The upper bits of parallel data (SSITDR, SSIRDR) are transferred prior to the lower bits. When data word length is 18, 20, 22, or 24 bits: 0: Parallel data (SSITDR, SSIRDR) is left-aligned. 1: Parallel data (SSITDR, SSIRDR) is right-aligned. • PDTA = 0



• PDTA = 1



Note: This bit has no meaning in direct transfer between this module and the SCUX. Use the SWAP function of the SCUX.

8	DEL	0	R/W	Serial Data Delay 0: 1 clock cycle delay between SSIWS and SSIDATA 1: No delay between SSIWS and SSIDATA

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	CKDV[3:0]	0000	R/W	Serial Oversampling Clock Division Ratio Sets the ratio between the oversampling clock (AUDIOφ) and the serial bit clock. When the SCKD bit is 0, the setting of these bits is ignored. The serial bit clock is used in the shift register and is supplied from the SSISCK pin. 0000: AUDIOφ 0001: AUDIOφ/2 0010: AUDIOφ/4 0011: AUDIOφ/8 0100: AUDIOφ/16 0101: AUDIOφ/32 0110: AUDIOφ/64 0111: AUDIOφ/128 1000: AUDIOφ/6 1001: AUDIOφ/12 1010: AUDIOφ/24 1011: AUDIOφ/48 1100: AUDIOφ/96 1101: Setting prohibited 1110: Setting prohibited 1111: Setting prohibited
3	MUEN	0	R/W	Mute Enable This bit is used to specify muting of the signals from this module during transmission. It is also used to specify the logical value to be output from the SSITxD pin when the MUEN bit is set to 0 with transfer disabled in WS continue mode. 0: This module is not muted. 1: This module is muted. Note: When this module is muted, serial data to be output is rewritten to 0 but data transmission in the module is not stopped. Write dummy data to the SSIFTDR not to generate a transmit underflow because the number of data in the transmit FIFO is decreasing.
2	—	0	R	Reserved The read value is undefined. The write value should always be 0.
1	TEN	0	R/W	Transmit Enable 0: Disables the transmit operation. 1: Enables the transmit operation. Note: When transmission stop/start is controlled by the SSI control register (SSICTRL_CIM) in the SCUX, set this bit to 0.
0	REN	0	R/W	Receive Enable 0: Disables the receive operation. 1: Enables the receive operation. Note: When reception stop/start is controlled by the SSI control register (SSICTRL_CIM) in the SCUX, set this bit to 0.

19.3.2 Status Register (SSISR)

SSISR consists of status flags indicating the operational status of this module and bits indicating the current channel numbers and word numbers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	-	-	-	-	-	-	-	-	-
Initial value:	Undefined	Undefined	0	0	0	0	1	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined
R/W:	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	TCHNO[1:0]		TSWNO	RCHNO[1:0]		RSWNO	IDST
Initial value:	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	Undefined	0	0	1	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note: * The bit can be read or written to. Writing 0 initializes the bit, but writing 1 is ignored.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	Undefined	R	Reserved The read value is undefined. The write value should always be 0.
29	TUIRQ	0	R/(W)*	Transmit Underflow Error Interrupt Status Flag This status flag indicates that transmit data was supplied at a lower rate than was required. This bit is set to 1 regardless of the value of the TUIEN bit and can be cleared by writing 0 to this bit. If TUIRQ = 1 and TUIEN = 1, an SSI interrupt occurs. If TUIRQ = 1, SSITDR did not have data written to it before it was required for transmission. This will lead to the same data being transmitted once more and a potential corruption of multi-channel data. As a result, this module will output erroneous data. Note: When an underflow error occurs, the current data in the data buffer of this module is transmitted until the next data is written.
28	TOIRQ	0	R/(W)*	Transmit Overflow Error Interrupt Status Flag This status flag indicates that transmit data was supplied at a higher rate than was required. This bit is set to 1 regardless of the value of the TOIEN bit and can be cleared by writing 0 to this bit. If TOIRQ = 1 and TOIEN = 1, an SSI interrupt occurs. If TOIRQ = 1, SSIFTDR had data written to it while the transmit FIFO is full (TDC = H'8). This will lead to the loss of data and a potential corruption of multi-channel data.
27	RUIRQ	0	R/(W)*	Receive Underflow Error Interrupt Status Flag This status flag indicates that receive data was supplied at a lower rate than was required. This bit is set to 1 regardless of the value of the RUIEN bit and can be cleared by writing 0 to this bit. If RUIRQ = 1 and RUIEN = 1, an SSI interrupt occurs. If RUIRQ = 1, SSIFRDR was read while the receive FIFO is empty (RDC = H'0).This can cause invalid receive data to be stored, which may lead to corruption of multi-channel data.
26	ROIRQ	0	R/(W)*	Receive Overflow Error Interrupt Status Flag This status flag indicates that receive data was supplied at a higher rate than was required. This bit is set to 1 regardless of the value of the ROIEN bit and can be cleared by writing 0 to this bit. If ROIRQ = 1 and ROIEN = 1, an SSI interrupt occurs. If ROIRQ = 1, SSIRDR was not read before there was new unread data written to it. This will lead to the loss of data and a potential corruption of multi-channel data. Note: When an overflow error occurs, the current data in the data buffer of this module is overwritten by the next incoming data from the SSI interface.

Bit	Bit Name	Initial Value	R/W	Description
25	IIRQ	1	R	Idle Mode Interrupt Status Flag This status flag indicates whether this module is in the idle state. This bit is set to 1 regardless of the value of the IIEN bit to allow polling. The interrupt can be masked by clearing IIEN to 0, but cannot be cleared by writing 0 to this bit. If IIRQ = 1 and IIEN = 1, an SSI interrupt occurs. 0: This module is not in idle state. 1: This module is in idle state.
24 to 7	—	Undefined	R	Reserved The read value is undefined. The write value should always be 0.
6, 5	TCHNO [1:0]	00	R	Transmit Channel Number These bits show the current channel number. These bits indicate the number of a channel whose data is required to be written to SSITDR. This value will change as the data is copied to the shift register, regardless of whether the data is written to SSITDR. When TDM or CONT is 1, these bits cannot be used.
4	TSWNO	1	R	Transmit Serial Word Number This status bit indicates the current word number. This bit indicates which system word is required to be written to SSITDR. This value will change as the data is copied to the shift register, regardless of whether the data is written to SSITDR. When TDM or CONT is 1, this bit cannot be used.
3, 2	RCHNO [1:0]	00	R	Receive Channel Number These bits show the current channel number. These bits indicate which channel the data in SSIRDR currently represents. This value will change as the data in SSIRDR is updated from the shift register. When TDM or CONT is 1, these bits cannot be used.
1	RSWNO	1	R	Receive Serial Word Number This status bit indicates the current word number. This bit indicates which system word the data in SSIRDR currently represents. This value will change as the data in SSIRDR is updated from the shift register, regardless of whether SSIRDR has been read. When TDM or CONT is 1, this bit cannot be used.
0	IDST	1	R	Idle Mode Status Flag This status flag indicates that the serial bus activity has stopped. This bit is cleared to 0 if the serial bus is currently active while TEN = 1 or REN = 1. This bit is automatically set to 1 if both TEN and REN are cleared to 0 and the current system word communication is completed. Note: If the external device stops the serial bus clock before the current system word is completed, this bit is not set.

Note: * The bit can be read or written to. Writing 0 initializes the bit, but writing 1 is ignored.

19.3.3 Transmit Data Register (SSITDR)

SSITDR is a 32-bit register that stores data to be transmitted. The data for transmission to be stored to SSITDR is automatically transferred from the transmit FIFO data register.

Data written to this register is transferred to the shift register upon transmission request. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR.

The CPU cannot read or write data from/to SSITDR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

19.3.4 Receive Data Register (SSIRDR)

SSIRDR is a 32-bit register that stores received data. The received data stored in SSIRDR is automatically transferred to the receive FIFO data register.

Data in this register is transferred from the shift register each time data word is received. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR.

The CPU cannot read or write data from/to SSIRDR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

19.3.5 FIFO Control Register (SSIFCR)

SSIFCR is a 32-bit readable/writable register that specifies the data trigger numbers for the transmit and receive FIFO data registers, and enables or disables FIFO data resets and interrupt requests.
SSIFCR can always be read or written by the CPU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	TTRG[1:0]		RTRG[1:0]		TIE	RIE	TFRST	RFRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7, 6	TTRG[1:0]	00	R/W	Transmit Data Trigger Number When the FIFO is operating for transmission, these bits specify the number of bytes for transmission in the FIFO (trigger number for transmission) at which the TDE flag in the FIFO status register (SSIFSR) will be set. The TDE flag is set to 1 when the number of bytes for transmission in the transmit FIFO data register (SSIFTDR) has fallen to or below the trigger number corresponding to the setting as shown below. 00: 7 (1)* 01: 6 (2)* 10: 4 (4)* 11: 2 (6)* Note: * The values in parentheses are the number of empty stages in SSIFTDR at which the TDE flag is set.
5, 4	RTRG[1:0]	00	R/W	Receive Data Trigger Number When the FIFO is operating for reception, these bits specify the number of received bytes in the FIFO (trigger number for reception) at which the RDF flag in the FIFO status register (SSIFSR) will be set. The RDF flag is set to 1 when the number of received bytes in the receive FIFO data register (SSIFRDR) has risen to or above the trigger number corresponding to the setting as shown below. 00: 1 01: 2 10: 4 11: 6
3	TIE	0	R/W	Transmit Interrupt Enable This bit enables or disables generation of transmit data empty interrupt (TXI) requests in the following situation: when the FIFO is operating for transmission, the data for transmission in the transmit FIFO data register (SSIFTDR) are transferred to the transmit data register (SSITDR) and the number of data bytes in the transmit FIFO data register has become less than the set transmit trigger number, so that the TDE flag in the FIFO status register (SSIFSR) is set to 1. 0: Transmit data empty interrupt (TXI) request is disabled. 1: Transmit data empty interrupt (TXI) request is enabled.* Note: * TXI can be cleared by clearing either the TDE flag (see the description of the TDE bit for details) or TIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
2	RIE	0	R/W	Receive Interrupt Enable Enables or disables generation of receive data full interrupt (RXI) requests when the RDF flag in the FIFO status register (SSIFSR) is set to 1 while the FIFO is operating for reception. 0: Receive data full interrupt (RXI) request is disabled. 1: Receive data full interrupt (RXI) request is enabled.* Note: * RXI can be cleared by clearing either the RDF flag (see the description of the RDF bit for details) or RIE bit to 0.
1	TFRST	0	R/W	Transmit FIFO Data Register Reset Invalidates the data in the transmit FIFO data register (SSIFTDR) to reset the FIFO to an empty state. 0: Reset is disabled.* 1: Reset is enabled. Note: * FIFO is reset at a power-on reset.
0	RFRST	0	R/W	Receive FIFO Data Register Reset Invalidates the data in the receive FIFO data register (SSIFRDR) to reset the FIFO to an empty state. 0: Reset is disabled.* 1: Reset is enabled. Note: * FIFO is reset at a power-on reset.

19.3.6 FIFO Status Register (SSIFSR)

SSIFSR contains status flags that indicate the state of operation of the transmit and receive FIFO data registers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	TDC[3:0]				-	-	-	-	-	-	-	TDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	RDC[3:0]				-	-	-	-	-	-	-	RDF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 24	TDC[3:0]	0000	R	Number of Data Bytes Stored in SSIFTDR TDC[3:0] = H'0 indicates no data for transmission. TDC[3:0] = H'8 indicates that 32 bytes of data for transmission is stored in SSIFTDR.
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	TDE	1	R/(W)*	Transmit Data Empty Indicates that, when the FIFO is operating for transmission, the data for transmission in the transmit FIFO data register (SSIFTDR) is transferred to the transmit data register (SSITDR), the number of data bytes in SSIFTDR has become less than the transmit trigger number specified by TTRG[1:0] in the FIFO control register (SSIFCR), and thus writing of transmit data to SSIFTDR has been enabled. 0: Number of data bytes for transmission in SSIFTDR is greater than the set transmit trigger number. [Clearing conditions] • 0 is written to TDE after data of the number of bytes larger than the set transmit trigger number is written to SSIFTDR. • The direct memory access controller is activated by transmit data empty (TXI) interrupt, and data of the number of bytes larger than the set transmit trigger number is written to SSIFTDR. 1: Number of data bytes for transmission in SSIFTDR is equal to or less than the set transmit trigger number.*1 [Setting conditions] • Power-on reset • Number of transmission data bytes stored in SSIFTDR has become equal to or less than the set transmit trigger number. Note: *1 Since SSIFTDR is an 8-stage FIFO register, the amount of data that can be written to it while TDE = 1 is "8 – transmit trigger number to be specified" bytes at maximum. Writing more data will be ignored. The number of data bytes in SSIFTDR is indicated in the TDC bits in SSIFSR.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	RDC[3:0]	0000	R	Number of Data Bytes Stored in SSIFRDR RDC[3:0] = H'0 indicates no received data. RDC[3:0] = H'8 indicates that 32 bytes of received data is stored in SSIFRDR.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	RDF	0	R/(W)*	Receive Data Full Indicates that, when the FIFO is operating for reception, the received data is transferred to the receive FIFO data register (SSIFRDR) and the number of data bytes in SSIFRDR has become greater than the receive trigger number specified by RTRG[1:0] in the FIFO control register (SSIFCR). 0: Number of received data bytes in SSIFRDR is less than the set receive trigger number. [Clearing conditions] • Power-on reset • 0 is written to RDF after the receive FIFO is emptied with writing 1 to RFRST. • 0 is written to RDF after data is read from SSIFRDR until the number of data bytes in SSIFRDR becomes less than the set receive trigger number. • The direct memory access controller is activated by receive data full (RXI) interrupt, and data is read from SSIFRDR until the number of data bytes in SSIFRDR becomes less than the set receive trigger number. 1: Number of received data bytes in SSIFRDR is equal to or greater than the set receive trigger number. [Setting condition] • Data of the number of bytes that is equal to or greater than the set receive trigger number is stored in SSIFRDR.*1 Note: *1 Since SSIFRDR is an 8-stage FIFO register, the amount of data that can be read from it while RDF = 1 is the set receive trigger number of bytes at maximum. Continuing to read data from SSIFRDR after reading all the data will result in undefined data to be read. The number of data bytes in SSIFRDR is indicated in the RDC bits in SSIFSR.

Note: * The bit can be read or written to. Writing 0 initializes the bit, but writing 1 is ignored.

19.3.7 Transmit FIFO Data Register (SSIFTDR)

SSIFTDR is a FIFO register consisting of eight stages of 32-bit registers for storing data to be serially transmitted. On detecting that the transmit data register (SSITDR) is empty, this module transfers the data for transmission written to SSIFTDR to SSITDR to start serial transmission, which can continue until SSIFTDR becomes empty. SSIFTDR can be written to by the CPU at any time.
Note that when SSIFTDR is full of transmit data (32 bytes), the next data cannot be written to it. If writing is attempted, it will be ignored and an overflow occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Note: * Not writable while FIFO is receiving data.

19.3.8 Receive FIFO Data Register (SSIFRDR)

SSIFRDR is a FIFO register consisting of eight stages of 32-bit registers for storing serially received data. When four bytes of data have been received, this module transfers the received data in the receive data register (SSIRDR) to SSIFRDR to complete reception operation. Reception can continue until 32 bytes of data have been stored to SSIFRDR. SSIFRDR can be read but cannot be written to by the CPU. Note that when SSIFRDR is read while it does not hold received data, the value read is undefined and a reception underflow will occur.
After SSIFRDR becomes full of received data, the data received thereafter will be lost and a receive overflow occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

19.3.9 TDM Mode Register (SSITDMR)

SSITDMR is a 32-bit readable/writable register that enables or disables muting of receive data in direct transfer, TDM mode, and WS continue mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RXD MUTE	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CONT	-	-	-	-	-	-	-	TDM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	RXDMUTE	0	R/W	Receive Direct Data Mute Setting When receive data is output directly to the SCUX, the output data is forcibly muted so that there is no signal (output as 0 data). 0: The receive data is output without change. 1: 0 data is output.
16	—	0	R/W	Reserved Always write 0 to this bit.
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CONT	0	R/W	WS Continue Mode 0: Disables WS continue mode. 1: Enables WS continue mode. Note: This bit can be set only in master mode (SCKD = 1 and SWSD = 1)
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TDM	0	R/W	TDM Mode 0: Disables TDM mode. 1: Enables TDM mode.

19.3.10 FC Control Register (SSIFCCR)

SSIFCCR is a 32-bit readable/writable register that controls frequency change detection.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	FIEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	FCEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	FIEN	0	R/W	Frequency Change Detection Interrupt Enable 0: Disables a frequency change detection interrupt. 1: Enables a frequency change detection interrupt.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	FCEN	0	R/W	Frequency Change Detection Enable When this bit is set to 1, counting up of cycles of peripheral clock 1 (P1φ) starts at the beginning of the next SSIWS cycle. On the start of each SSIWS cycle, the current counted value is moved to the VALUE bits in the FC Status Register (SSIFCSR). The counter is then cleared to 0 and counting up is resumed. When this bit is set to 0, the counter is cleared to 0 and counting up is stopped. 0: Disables frequency change detection. 1: Enables frequency change detection. Note: Set this bit to 1 after setting the desired values in SSICR, SSIFCMR, and SSITDMR.

19.3.11 FC Mode Register (SSIFCMR)

SSIFCMR sets the maximum and minimum allowable numbers of cycles of the peripheral clock 1 (P1ϕ) for each SSIWS cycle, when frequency change detection is enabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	MAXV													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	MINV													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	MAXV	0	R/W	Maximum Value Sets the maximum allowable number of cycles of the peripheral clock 1 (P1φ) for each SSIWS cycle, when SSIFCCR.FCEN = 1.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	MINV	0	R/W	Minimum Value Sets the minimum allowable number of cycles of the peripheral clock 1 (P1φ) for each SSIWS cycle, when SSIFCCR.FCEN = 1.

19.3.12 FC Status Register (SSIFCSR)

SSIFCSR consists of the frequency change detection status flag and the bits that indicate the current cycle count of the peripheral clock 1 (P1ϕ).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	FCIRQ	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/(W)*	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	VALUE													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FCIRQ	0	R/(W)*	Frequency Change Detection Error Interrupt Status Indicates VALUE > SSIFCMR.MAXV or 0 < VALUE < SSIFCMR.MINV when SSIFCCR.FCEN = 1. This bit is set to 1 regardless of the setting of the FIEN bit in SSIFCCR. Write 0 to clear this flag to 0. When FCIRQ = 1 and SSIFCCR.FIEN = 1, an SSI interrupt is generated.
23 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VALUE	0	R	VALUE Indicates the current cycle count of the peripheral clock 1 (P1φ) in an SSIWS cycle, when SSIFCCR.FCEN = 1. Each time the next SSIWS cycle starts, the value is updated. Note: When the SSISCK signal stops, the start of an SSIWS cycle cannot be detected. Consequently, the value is not updated.

Note: * The bit can be read or written to. Writing 0 initializes the bit, but writing 1 is ignored.

19.4 Operation Description

19.4.1 Bus Format

This module can operate as a transmitter or a receiver and can be configured into many serial bus formats in either mode. The bus format can be selected from one of the twelve major modes shown in Table 19.3.

Table 19.3 Bus Format for SSIF Module

	TEN	REN	SCKD	SWSD	TDM	MUEN	IIEN	TOIEN	TUIEN	ROIEN	RUIEN	CONT	SWSP	DEL	PDTA	SDTA	SPDP	SCKP	SWL[2:0]	DWL[2:0]	CHNL[1:0]
Non-Compression Slave Receiver	0	1	0	0	0	Control Bits							Configuration Bits								
Non-Compression Slave Transmitter	1	0	0	0	0																
Non-Compression Slave Transceiver*	1	1	0	0	0																
Non-Compression Master Receiver	0	1	1	1	0																
Non-Compression Master Transmitter	1	0	1	1	0																
Non-Compression Master Transceiver*	1	1	1	1	0																
TDM Slave Receiver	0	1	0	0	1								0	Configuration Bits							
TDM Slave Transmitter	1	0	0	0	1								0								
TDM Slave Transceiver*	1	1	0	0	1								0								
TDM Master Receiver	0	1	1	1	1								0								
TDM Master Transmitter	1	0	1	1	1								0								
TDM Master Transceiver*	1	1	1	1	1								0								

Note: * Set the TEN and REN bits to 1 at the same time when using transceiver mode.

19.4.2 Non-Compressed Modes

The non-compressed modes support all serial audio streams split into channels. It supports the I^{2}S compatible format as well as many more variants on these modes.

(1) Slave Receiver

This mode allows the module to receive serial data from another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(2) Slave Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(3) Slave Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(4) Master Receiver

This mode allows the module to receive serial data from another device. The clock and word select signals are internally derived from the oversampling clock. The format of these signals is defined in the configuration fields of this module. If the incoming data from another device does not follow the configured format, operation is not guaranteed.

(5) Master Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signals are internally derived from the oversampling clock. The format of these signals is defined in the configuration fields of this module.

(6) Master Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signals are internally derived from the oversampling clock. The format of these signals is defined in the configuration fields of this module.

(7) Operation Setting Related to Word Length

All bits related to the SSICR's word length are valid in non-compressed modes. There are many configurations this module supports, but some of the combinations are shown below for the I^{2}S compatible format, MSB-first and left-aligned format, and MSB-first and right-aligned format.

- I²S Compatible Format

Figure 19.2 and Figure 19.3 show the I²S compatible formats without and with padding, respectively. Padding occurs when the data word length is smaller than the system word length.

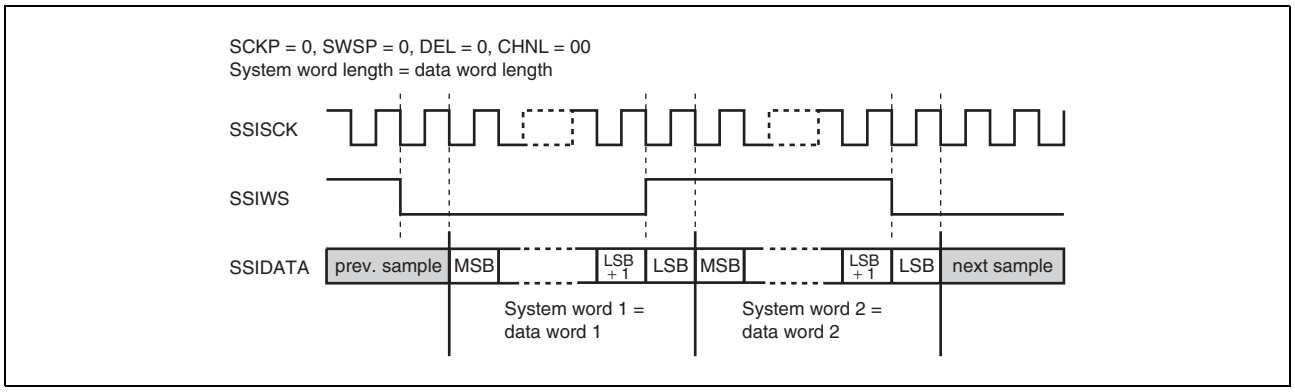

Figure 19.2 I²S Compatible Format (without Padding)

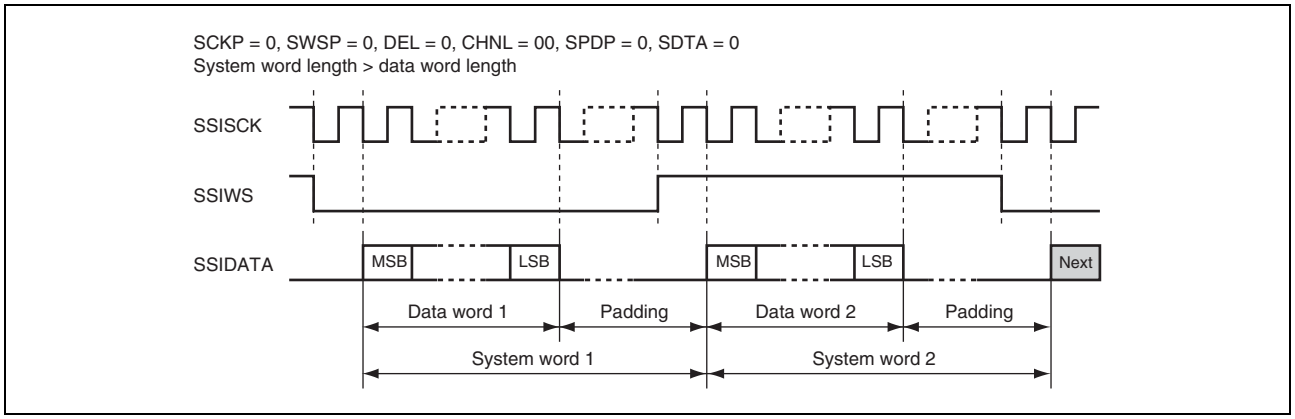

Figure 19.3 I²S Compatible Format (with Padding)

Figure 19.4 shows the MSB-first and left-aligned format and Figure 19.5 shows the MSB-first and right-aligned format.

- MSB-first and Left-aligned Format

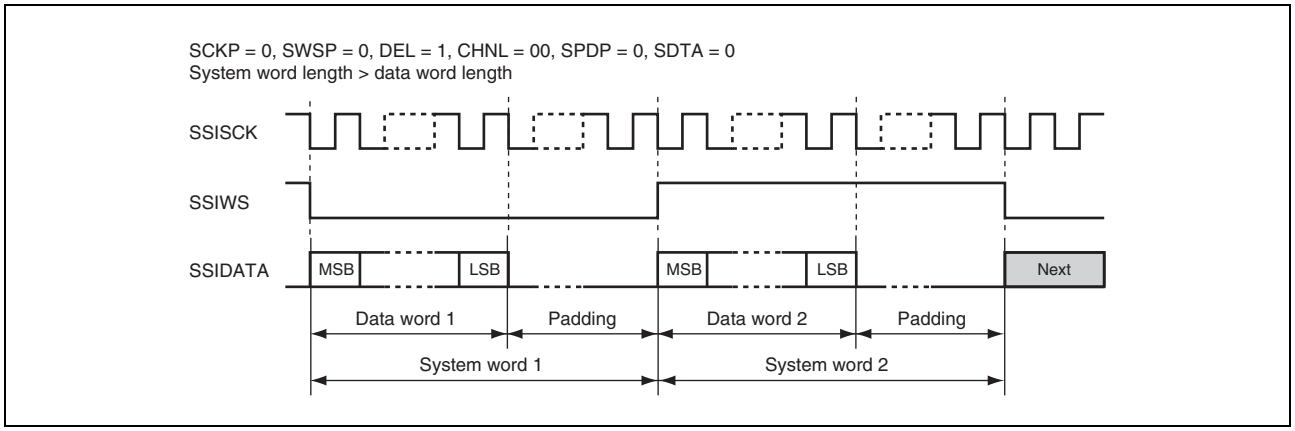

Figure 19.4 MSB-first and Left-aligned Format (Transmitted and Received in the Order of Serial Data and Padding Bits)

- MSB-first and Right-aligned Format

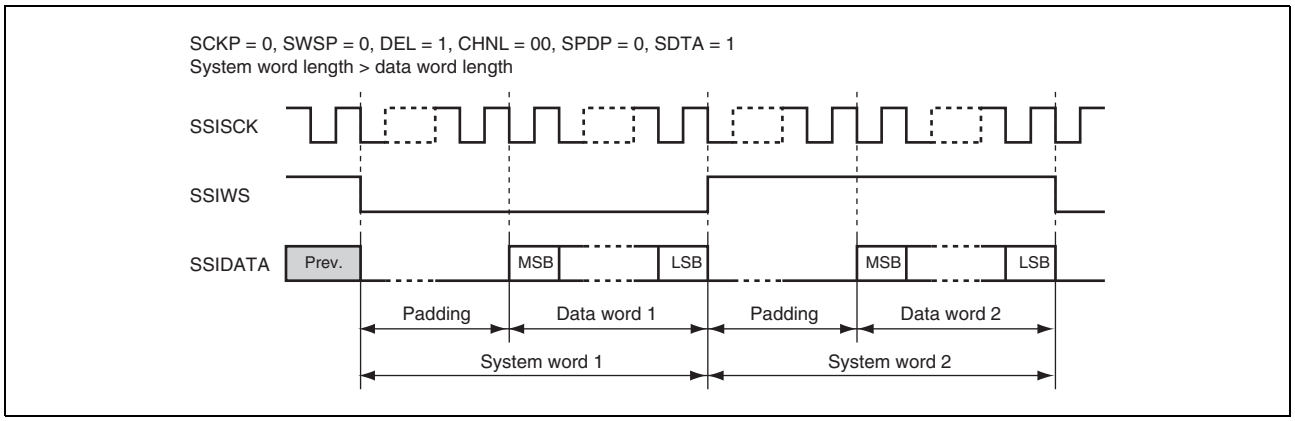

Figure 19.5 MSB-first and Right-aligned Format (Transmitted and Received in the Order of Padding Bits and Serial Data)

(8) Multi-channel Formats

Some devices extend the definition of the I²S bus specification and allow more than 2 channels to be transferred within two system words.

This module supports the transfer of 4, 6, and 8 channels by using the CHNL, SWL and DWL bits only when the system word length (SWL) is greater than or equal to the data word length (DWL) multiplied by channels (CHNL).

Table 19.4 shows the number of padding bits for each of the valid setting. If setting is not valid, "—" is indicated instead of a number.

Table 19.4 The Number of Padding Bits for Each Valid Setting

Padding Bits per System Word			DWL[2:0]	000	001	010	011	100	101	110
CHNL [1:0]	Decoded Channels per System Word	SWL [2:0]	Decoded Word Length	8	16	18	20	22	24	32

		111	256	224	192	184	176	168	160	128

When this module acts as a transmitter, each word written to SSITDR is transmitted to the serial audio bus in the order they are written. When this module acts as a receiver, each word received by the serial audio bus is read from the SSIRDR register in the order they are received.

Figure 19.6 to Figure 19.8 show how the data on 4, 6, and 8 channels are transferred to the serial audio bus. Note that there are no padding bits in the first example (Figure 19.6), the second example (Figure 19.7) is left-aligned and the third (Figure 19.8) is right-aligned. The other conditions in these examples have been selected arbitrarily.

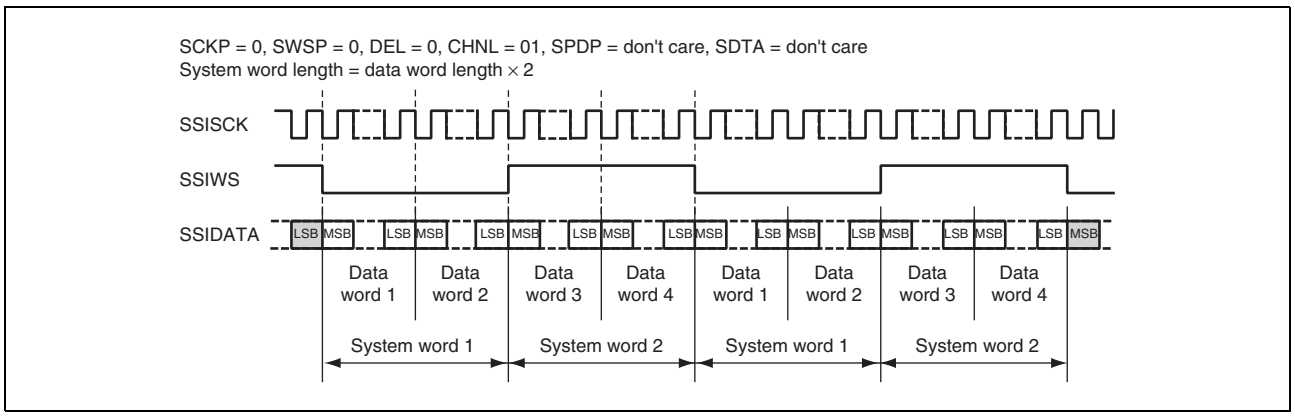

Figure 19.6 Multi-Channel Format (4 Channels Without Padding)

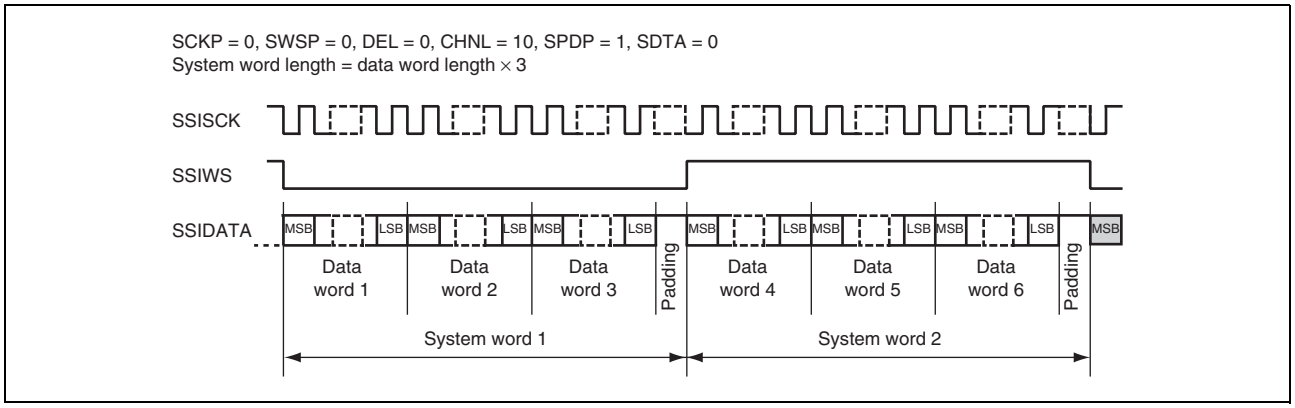

Figure 19.7 Multi-Channel Format (6 Channels with High Padding)

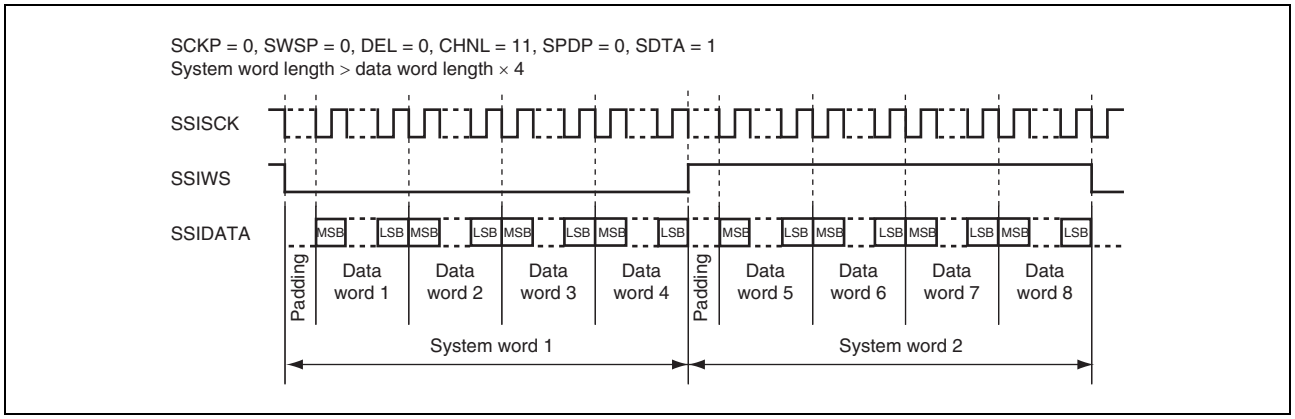

Figure 19.8 Multi-Channel Format (8 Channels; Transmitting and Receiving in the Order of Padding Bits and Serial Data ; with Padding)

(9) Operation Format Configuration Bits

Several more configuration bits in non-compressed mode are shown below. These bits are not mutually exclusive, but some combinations may not be useful.
These configuration bits are described below with reference to the basic sample format in Figure 19.9.

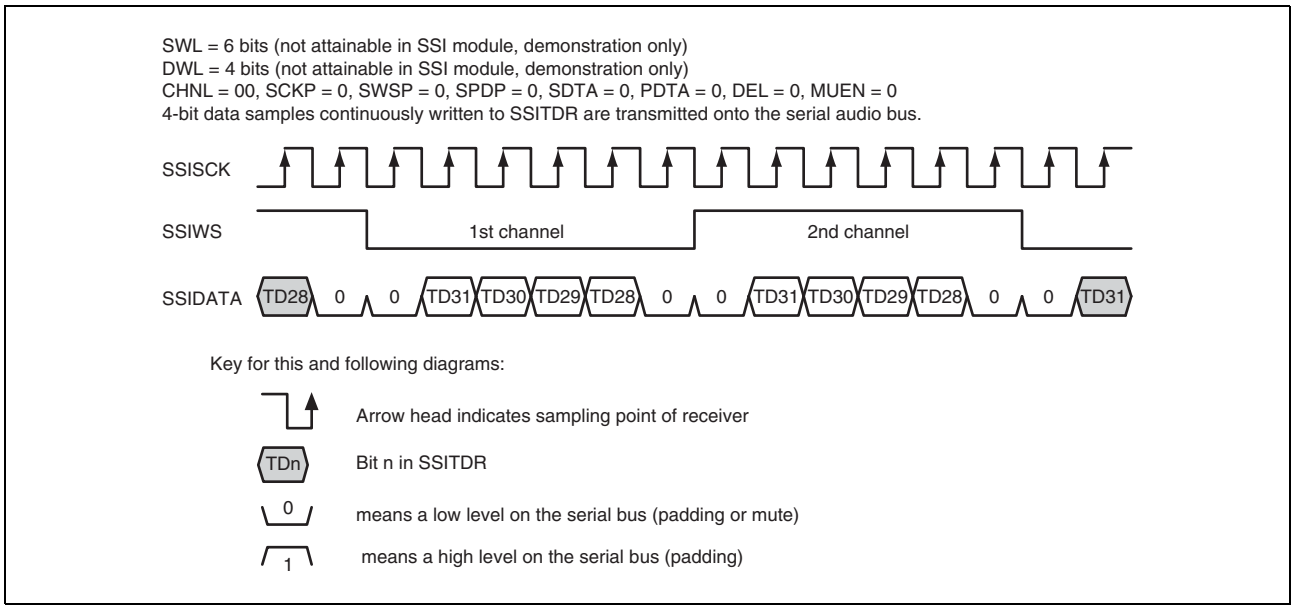

Figure 19.9 Basic Sample Format (Transmit Mode with Example System/Data Word Length)

Figure 19.9 uses a system word length of 6 bits and a data word length of 4 bits. These settings are not possible with this module but are used as an example only for clarification of the other configuration bits.

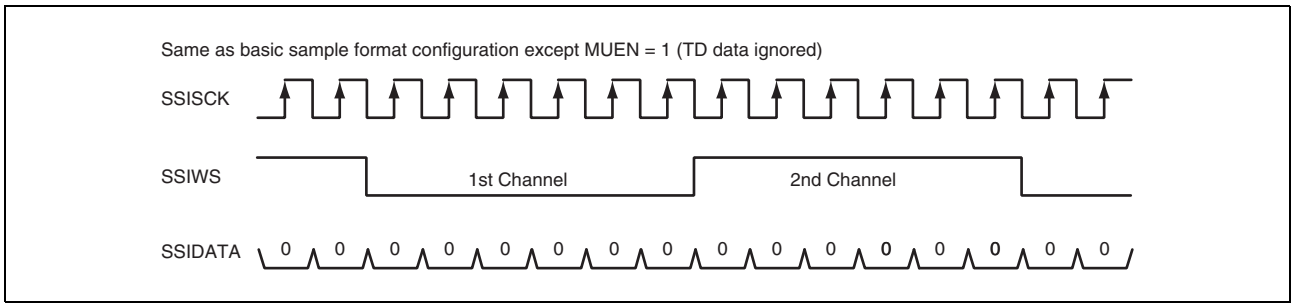

Figure 19.17 Mute Enabled

19.4.3 TDM Mode

TDM mode is provided to enable connection to multi-channel devices for TDM. This mode can be set using the TDM bit in the TDM mode register (SSITDMR). In this mode, the SSIWS signal is high only for system word 1 period and low for the other periods. The pulse produced on the SSIWS signal is defined as SYNC pulse. Note that the SYNC pulse always has the positive polarity (high only for system word 1 period).
Figure 19.18 and Figure 19.19 show the TDM formats without and with padding, respectively.

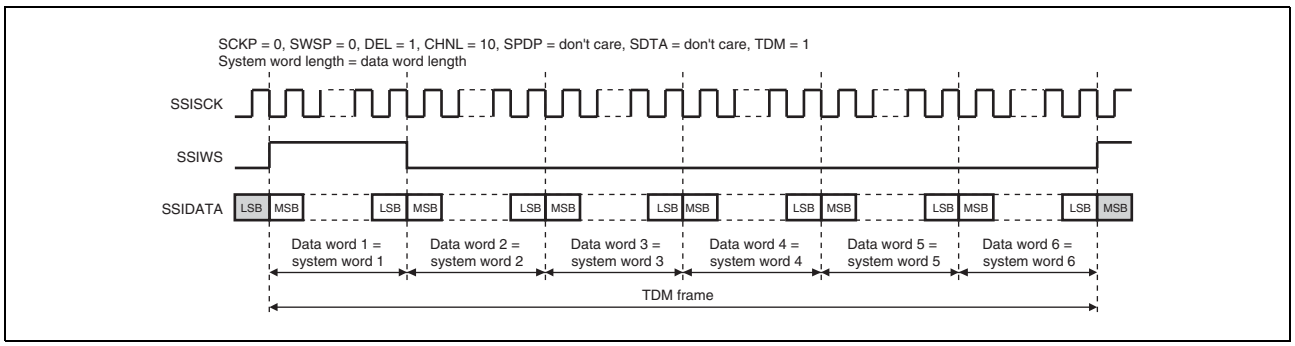

Figure 19.18 TDM Format (6 system words, no padding)

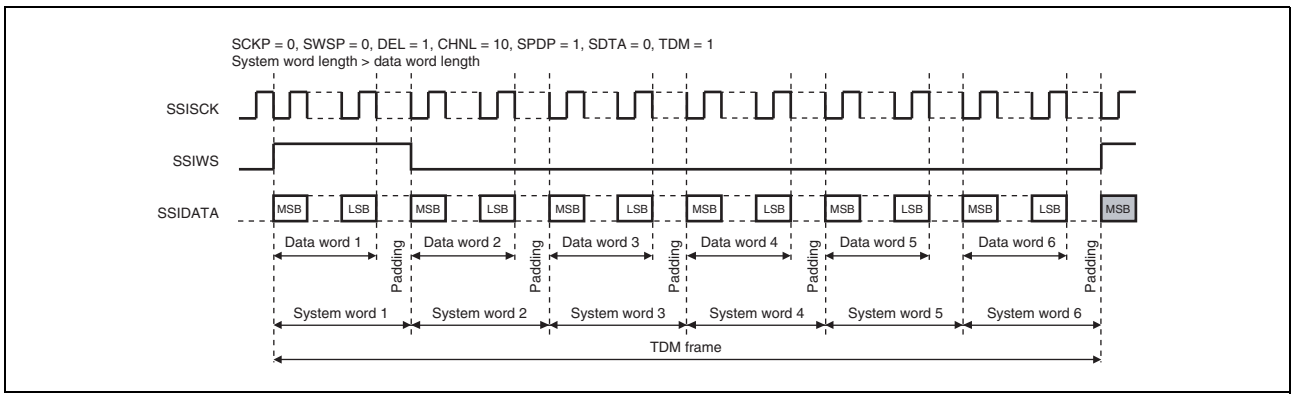

Figure 19.19 TDM Format (6 system words, with padding)

19.4.4 WS Continue Mode

In WS continue mode, the SSIWS signal continues to be output irrespective whether data transfer is enabled or disabled. This mode can be set using the CONT bit in the TDM mode register (SSITDMR). With this mode enabled, the SSIWS signal does not stop but continues operating even if TEN and REN bits in the control register (SSICR) are both set to 0 (transfer disabled). While transfer is disabled, the SSITxD pin outputs 0 if the MUEN bit in SSICR is set to 0, and outputs the value specified by the SPDP bit in SSICR if the MUEN bit is set to 0. With this mode disabled, the SSIWS signal stops if TEN and REN bits are both set to 0.
Figure 19.20 and Figure 19.21 show the operations with WS continue mode enabled and disabled, respectively.

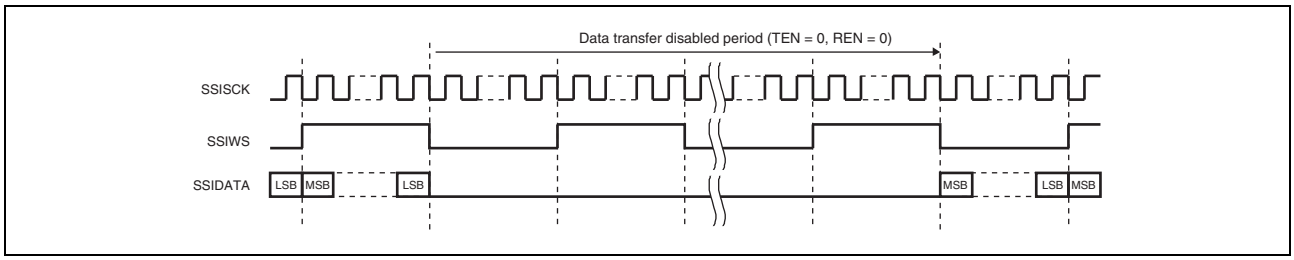

Figure 19.20 WS Continue Mode Enabled

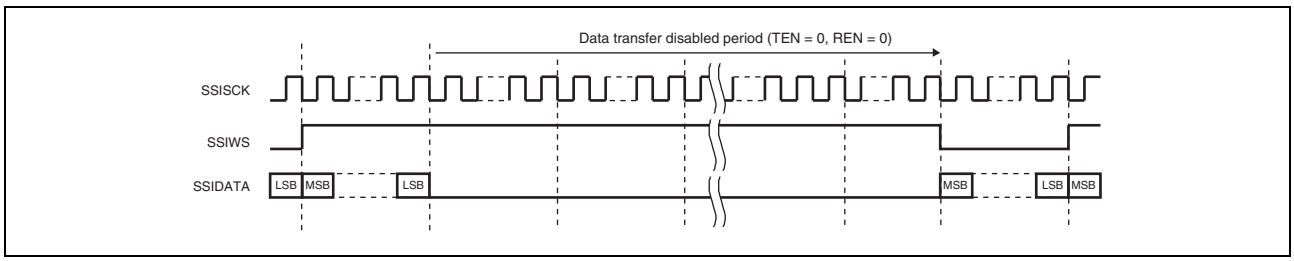

Figure 19.21 WS Continue Mode Disabled

19.4.5 Operation Modes

There are three modes of operation: configuration, enabled and disabled. Figure 19.22 shows how the module enters each of these modes.

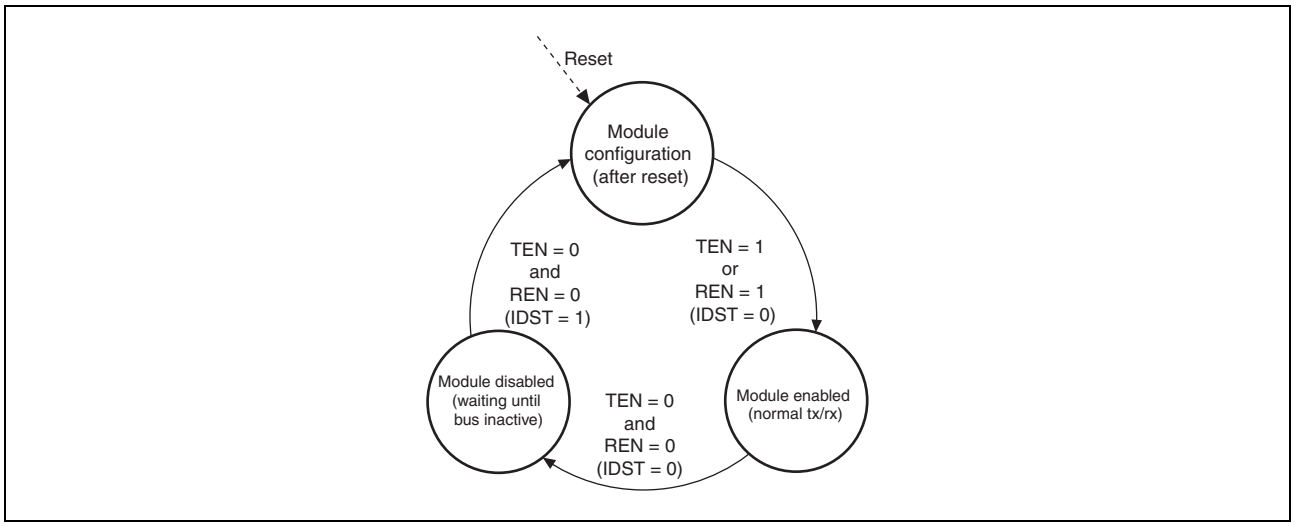

Figure 19.22 Operation Modes

(1) Configuration Mode

This mode is entered after the module is released from reset. All required configuration fields in the control register should be defined in this mode, before this module is enabled by setting the TEN and REN bits.
Setting the TEN and REN bits causes the module to enter the module enabled mode.

(2) Module Enabled Mode

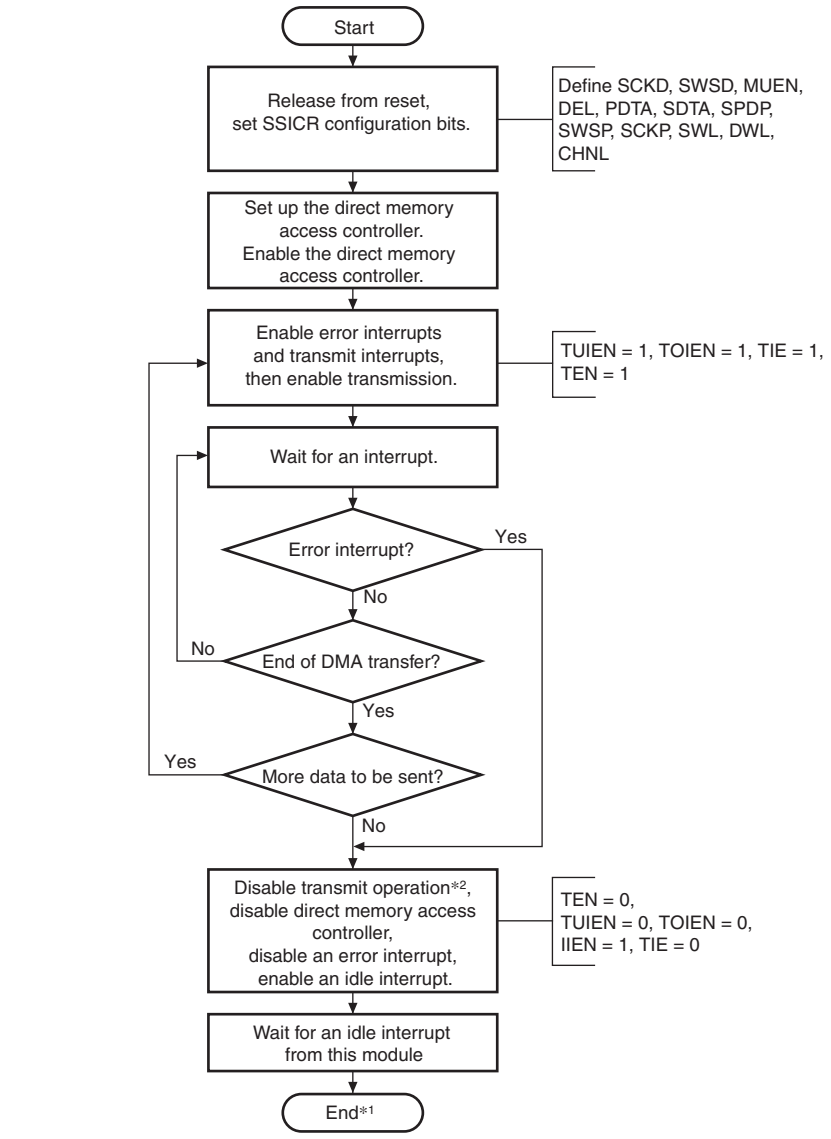
Operation of the module in this mode is dependent on the operation mode selected. For details, refer to section 19.4.6, Transmit Operation, and section 19.4.7, Receive Operation, below.

19.4.6 Transmit Operation

Transmission can be controlled either by DMA transfer or interrupt.
DMA control is preferred to reduce the processor load. In DMA control mode, the processor will only receive interrupts if there is an underflow or overflow of data or if the DMA transfer has been completed.
The alternative method is using the interrupts that this module generates to supply data as required.
When disabling this module, the clock* must be kept supplied to this module until the IIRQ bit indicates that the module is in the idle state.
Figure 19.23 shows the transmit operation in DMA control mode, and Figure 19.24 shows the transmit operation in interrupt control mode.

Note: * Input clock from the SSISCK pin when SCKD = 0.
Oversampling clock when SCKD = 1.

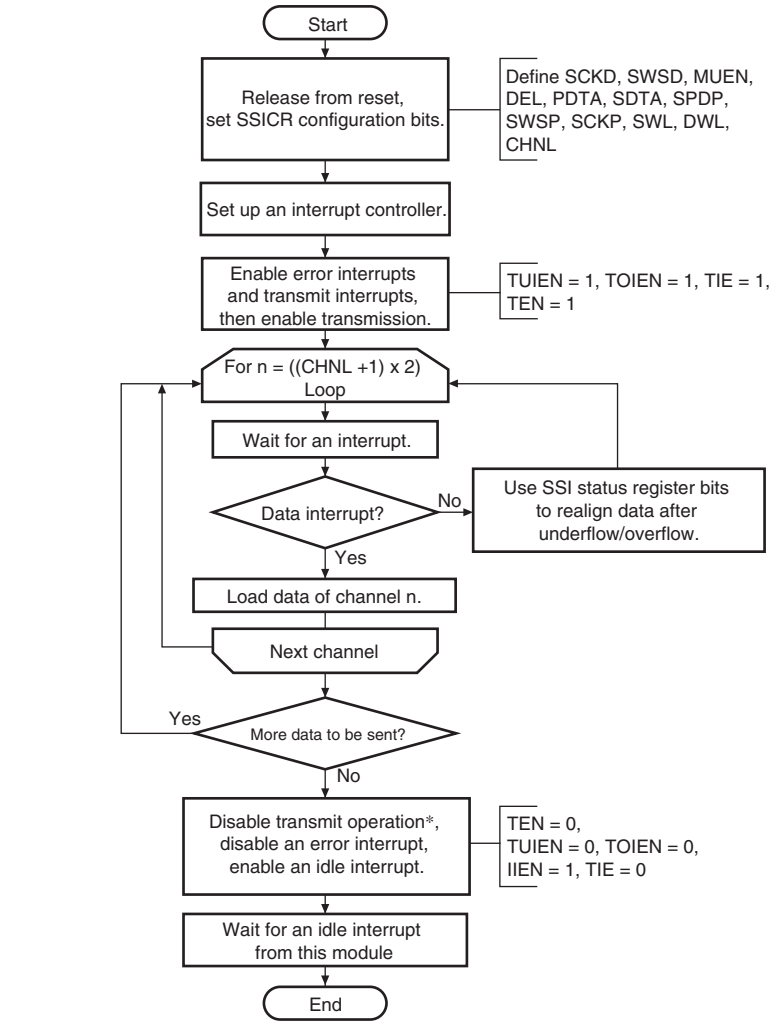
(1) Transmission Using Direct Memory Access Controller



Notes: 1. If an error interrupt (underflow/overflow) occurs, go back to the start in the flowchart again.
2. When WS continue mode is disabled, to restart the transmission after it is disabled (TEN = 0), perform a software reset and then go back to the start in the flowchart again.

Figure 19.23 Transmission Using Direct Memory Access Controller

(2) Transmission Using Interrupt-Driven Data Flow Control



Note: * When WS continue mode is disabled, to restart the transmission after it is disabled (TEN = 0), perform a software reset and then go back to the start in the flowchart again.

Figure 19.24 Transmission Using Interrupt-Driven Data Flow Control

19.4.7 Receive Operation

Like transmission, reception can be controlled either by DMA transfer or interrupt.

Figure 19.25 and Figure 19.26 show the flow of operation.

When disabling this module, the clock* must be kept supplied to this module until the IIRQ bit indicates that the module is in the idle state.

Note: * Input clock from the SSISCK pin when SCKD = 0.
Oversampling clock when SCKD = 1.

(1) Reception Using Direct Memory Access Controller

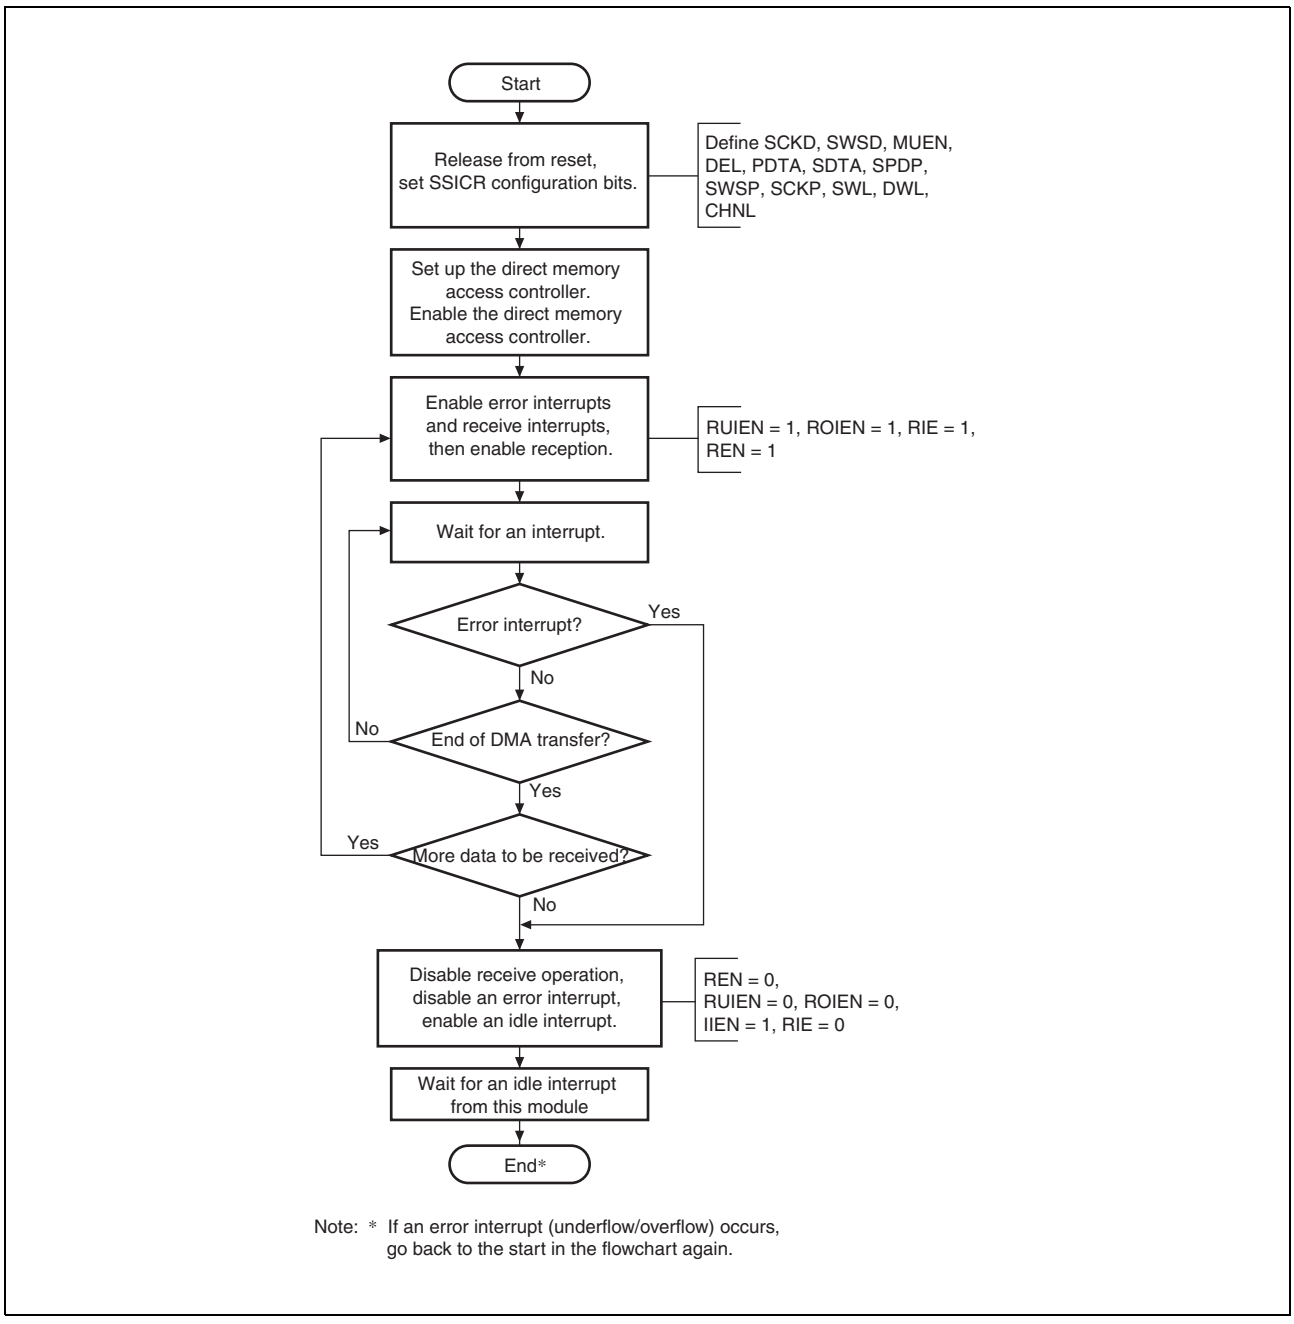


Figure 19.25 Reception Using Direct Memory Access Controller

(2) Reception Using Interrupt-Driven Data Flow Control

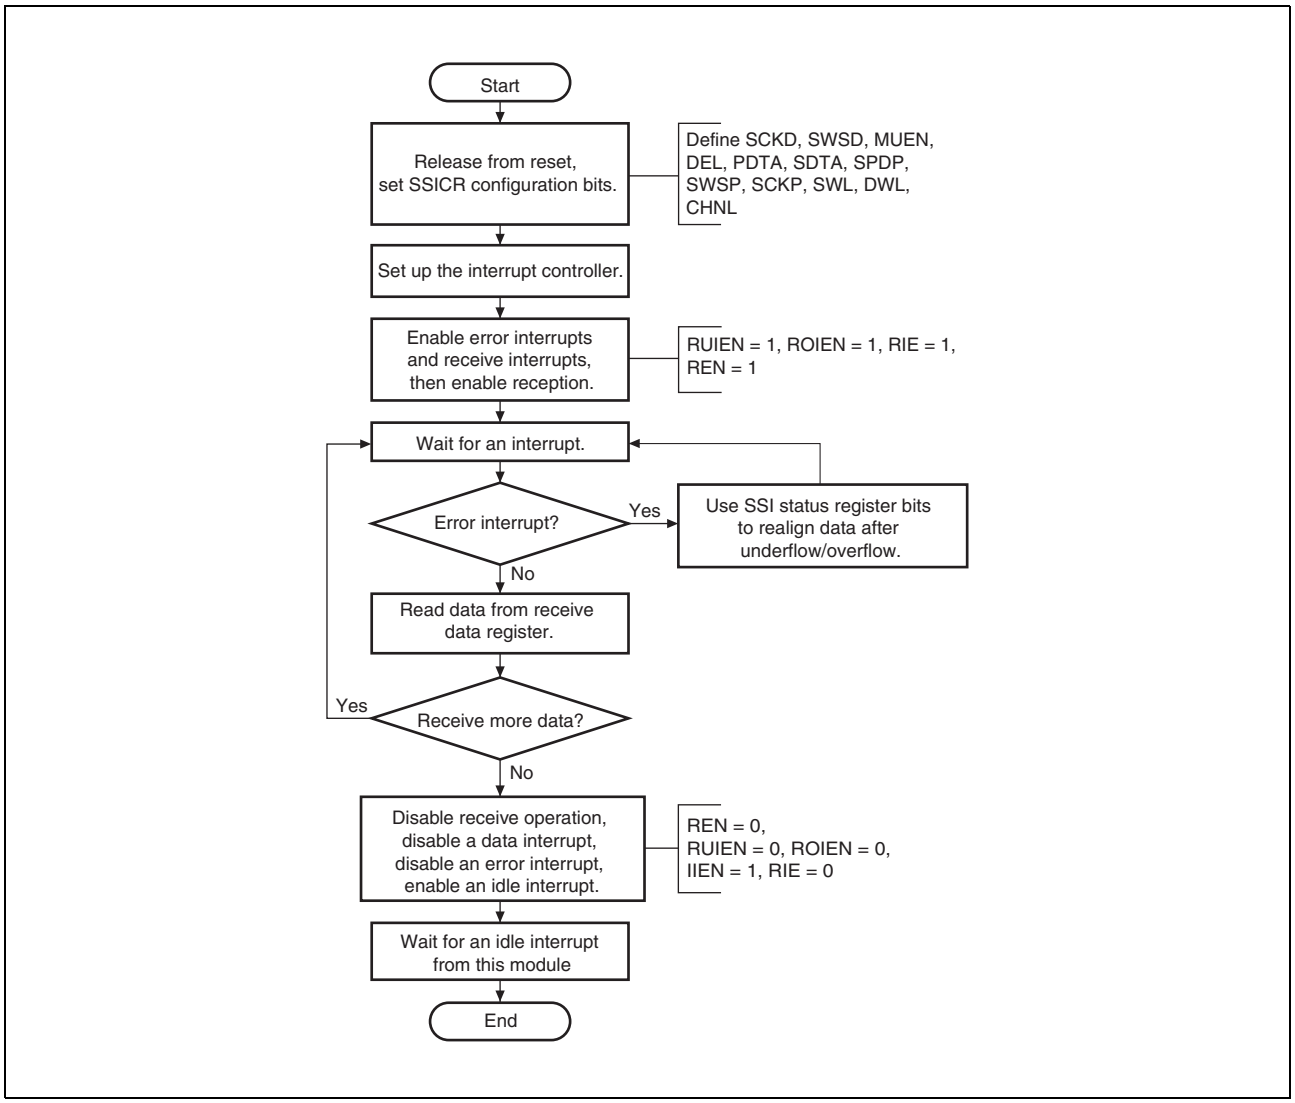

Figure 19.26 Reception Using Interrupt-Driven Data Flow Control

When an underflow or overflow error condition has matched, this module can be recovered to the status before underflow or overflow condition match by using the TCHNO [1:0] and TSWNO bits in transmission and the RCHNO[1:0] and RSWNO bits in reception. When an underflow or overflow occurs, the host CPU can read the channel number and system word number to determine what point the serial audio stream has reached. In the transmitter case, the host CPU can skip forward through the data it wants to transmit until it finds the sample data that matches what this module is expecting to transmit next, and so resynchronize with the audio data stream. In the receiver case the host CPU can store null data to make the number of receive data items consistent until it is ready to store the sample data that this module is indicating will be received next, and so resynchronize with the audio data stream.

19.4.8 Serial Bit Clock Control

This function is used to control and select the clock that is used for the serial bus interface.
If the serial bit clock direction is set to input (SCKD = 0), this module is in clock slave mode and the shift register uses the bit clock that was input to the SSISCK pin.
If the serial bit clock direction is set to output (SCKD = 1), this module is in clock master mode, and the shift register uses the oversampling clock or a divided oversampling clock as the bit clock. The oversampling clock is divided by the ratio specified by the serial oversampling clock division ratio bits (CKDV) in SSICR for use as the bit clock by the shift register.
In either case above, the output of the SSISCK pin is the same as the bit clock.

19.5 Usage Notes

19.5.1 Limitations from Underflow or Overflow during DMA Operation

If an underflow or overflow occurs while the DMA is in operation, the module should be restarted. The transmit and receive buffers in the SSIF consists of 32-bit registers that share the L and R channels. Therefore, data to be transmitted and received at the L channel may sometimes be transmitted and received at the R channel if an underflow or overflow occurs, for example, under the following condition: the control register (SSICR) has a 32-bit setting for both data word length (DWL2 to DWL0) and system word length (SWL2 to SWL0).
If an error interrupt (transmit underflow, transmit overflow, receive underflow, and receive overflow) or setting of a corresponding error status flag (the bits TUIRQ, TOIRQ, RUIRQ, and ROIRQ in SSISR) indicates an error, write 0 to the TEN or REN bit in SSICR to disable DMA transfer requests from this module, thus stopping the operation. Make the setting to stop the direct memory access controller. After this, if reception had been in progress, write 0 to the error status flag bit to clear it, set the direct memory access controller again, and restart the transfer. For transmission, issue a software reset and execute the procedure to start again.

19.5.2 Note on Changing Mode from Master Transceiver to Master Receiver

If a transmit underflow occurs in master transceiver mode while WS continue mode is disabled (SSITDMR.CONT = 0) and the TEN bit in SSICR is set to 0 in order to disable transmit operation, SSIWS output is broken. In order to receive seamlessly after changing mode to master receiver mode, write dummy data to SSIFTDR to suppress transmit underflow.

19.5.3 Limits on TDM mode and WS Continue Mode

If TDM mode or WS continue mode setting is changed, the operation of the SSISCK and SSIWS signals immediately after switching are not guaranteed. If it affects the device to be connected, do not change the setting dynamically.
To temporarily halt and restart transmission while the WS continue mode is enabled (SSITDMR.CONT = 1), after writing to the transmit FIFO data register (SSIFTDR) a multiple of two times, use the transmit underflow error interrupt or the corresponding error status flag (SSISR.TUIRQ) to confirm that an error has occurred, and then write 0 to the TEN bit of the SSISCR register.
Note that after the transmit underflow error, the last value written to SSIFTDR will be repeatedly sent as long as SSISCR.TEN = 1. Therefore, write a dummy value as the last data for transmission or mute the signal by writing 1 to the MUEN bit of the SSISCR register.
To restart transmission, do not apply a software reset; after writing 0 to the error status flag bit to clear it, use the idle mode status flag (SSISR.IDST) to confirm that this module is in the idle state, and then write 1 to the TEN bit of the SSISCR register.

20. Media Local Bus

This module is only incorporated in the RZ/A1L.
This product supports the media local bus as an interface to connect to the MOST controller.

20.1 Features

- 3-pin interface
- A maximum of 50 Mbps of data can be transferred.

For details on the functions and registers, contact Renesas Electronics Corporation's sales office.

Figure 20.1 shows the block diagram.

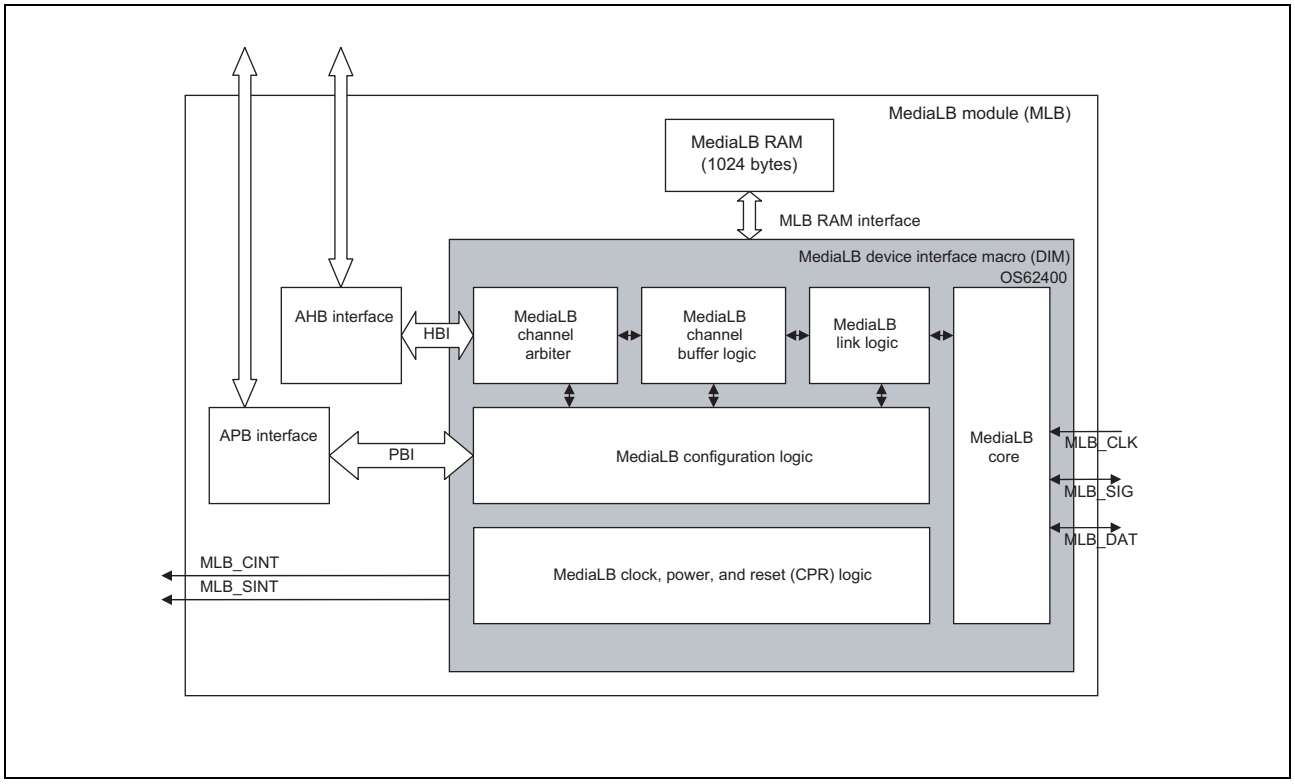

Figure 20.1 Block Diagram

20.2 Input/Output Pins

Table 20.1 shows the pin configuration.

Table 20.1 Pin Configuration

Pin Name	I/O	Description
MLB_CLK	I	MediaLB clock input
MLB_SIG	I/O	MediaLB signal information I/O
MLB_DAT	I/O	MediaLB data I/O

20.3 Register Description

Table 20.2 shows the register configuration.

For details on the registers, contact Renesas Electronics Corporation's sales office.

Table 20.2 Register Configuration

	Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Configuration control register	Device control configuration register	DCCR	*1	*1	H'E8034000	32
	System status configuration register	SSCR	*1	*1	H'E8034004	32
	System data configuration register	SDCR	*1	*1	H'E8034008	32
	System mask configuration register	SMCR	*1	*1	H'E803400C	32
	Version control configuration register	VCCR	*1	*1	H'E803401C	32
	Synchronous base address configuration register	SBCR	*1	*1	H'E8034020	32
	Asynchronous base address configuration register	ABCR	*1	*1	H'E8034024	32
	Control base address configuration register	CBCR	*1	*1	H'E8034028	32
	Isochronous base address configuration register	IBCR	*1	*1	H'E803402C	32

Channel m*2 configuration register	Channel m entry configuration register	CECRm	*1	*1	H'E8034040 + m x 10	32
	Channel m status configuration register	CSCRm	*1	*1	H'E8034044 + m x 10	32
	Channel m current buffer configuration register	CCBCRm	*1	*1	H'E8034048 + m x 10	32
	Channel m next buffer configuration register	CNBCRm	*1	*1	H'E803404C + m x 10	32
	Local channel m buffer configuration register	LCBCRm	*1	*1	H'E8034280 + m x 4	32

Note 1. Contact Renesas Electronics Corporation's sales office.
Note 2. Each channel of the media local bus is identified by “m” (m = 0 to 30).

21. CAN Interface

This section gives an overall description of the CAN interface (RS-CAN).

The first section describes the features specific to this LSI, including the number of units and the register base addresses. The subsequent sections describe the RS-CAN's functions and registers.

21.1 Overview

21.1.1 Units

This microcontroller incorporates the following number of units of the CAN interface (RS-CAN).

Table 21.1 Units of RS-CAN

	RS-CAN
Number of units	1
Name	RSCAN0

The RS-CAN has two channels.

Table 21.2 Channels of RS-CAN

	RS-CAN
Number of channels	2
Name	CAN0, CAN1

Table 21.3 Index

Index	Meaning	Available Number of CAN Channels and Index
		2 channels
n	Throughout this section, the unit of the RS-CAN is identified by the index "n": for example, RSCANnGCFG is the global configuration register in the RS-CANn unit.	n = 0
m	Throughout this section, the individual channels in the RS-CAN units are identified by the index "m": for example, RSCAN0CmSTS is the channel m status register in the RS-CAN0 unit.	m = 0 or 1
j	The individual receive rule table registers in the RS-CAN units are identified by the index "j": for example, RSCAN0GAFLIDj is the receive rule ID register j in the RS-CAN0 unit.	j = 0 to 15
k	The individual transmit/receive FIFO in the RS-CAN units are identified by the index "k" (k = 0 to channel m × 3 + 2): for example, RSCAN0CFCCk is the transmit/receive FIFO buffer configuration and control register k in the RS-CAN0 unit.	k = 0 to 5
q	The individual receive buffer in the RS-CAN units are identified by the index "q" (q = 0 to channel m × 16 + 15): for example, RSCAN0RMIDq is the receive buffer ID register q in the RS-CAN0 unit.	q = 0 to 31
p	The individual transmit buffers in the RS-CAN units are identified by the index "p" (p = 0 to channel m × 16 + 15): for example, RSCAN0TMCp is the transmit buffer control register p in the RS-CAN0 unit.	p = 0 to 31
y	When the registers other than above are collectively explained, they are identified by the index "y" (y = 0): for example, RSCAN0RMNDy is the receive buffer new data register in the RS-CAN0 unit.	y = 0

21.1.2 Register addresses

RS-CAN base addresses are listed in the following table.

RS-CAN register addresses are given as offsets from the base addresses.

Table 21.4 Register base address

Base Address Name	Base Address
<RSCAN0_base>	E803 A000$_H$

21.1.3 Clock supply

The RS-CAN provides two clock inputs:

Table 21.5 RS-CAN clock supply

Module	RS-CAN clock Clock	Connected to
RSCAN0	clk_xincan	CAN_CLK
	clkc	P1ϕ/2
	pclk	P1ϕ

The operating frequency of the RS-CAN depends on the transfer rate and the number of channels in use. Table 21.6 shows the range of the frequency.

Table 21.6 Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in this LSI

Condition		Range of Operating Frequency		
Transfer Rate	No. of Channels in Use	pclk	clk_xincan*1	clkc*1, *2
1 Mbps	2ch	pclk ≥ 26 MHz	8 MHz ≤ clk_xincan ≤ pclk/2	12.5 MHz ≤ clkc ≤ pclk/2
	1ch	pclk ≥ 18 MHz		
500 kbps	2ch	pclk ≥ 13 MHz	4 MHz ≤ clk_xincan ≤ pclk/2	12.5 MHz ≤ clkc ≤ pclk/2
	1ch	pclk ≥ 8 MHz		
125 kbps	2ch	pclk ≥ 8 MHz	4 MHz ≤ clk_xincan ≤ pclk/2	12.5 MHz ≤ clkc ≤ pclk/2
	1ch			

Note 1. Setting the DCS bit in RSCAN0GCFG enables to select either clk_xincan or clkc. Set clocks less than or equal to pclk/2.

Note 2. Select clk_xincan when pclk < 25 MHz.

21.1.4 Interrupts

The Controller Area Network (RS-CAN) can generate the interrupt requests shown in the following table.

Table 21.7 RS-CAN interrupt requests

Unit Interrupt Name	Outline	Interrupt ID	DMA Trigger Number
	RSCAN0		
INTRCANGERR	CAN global error interrupt	253	—
INTRCANGRECC	CAN receive FIFO interrupt	254	—
	CAN0		
INTRCANmERR (m = 0)	CAN0 error interrupt	256	—
INTRCANmREC (m = 0)	CAN0 transmit/receive FIFO receive completion interrupt	255	—
INTRCANmTRX (m = 0)	CAN0 transmit interrupt	257	—
	CAN1		
INTRCANmERR (m = 1)	CAN1 error interrupt	259	—
INTRCANmREC (m = 1)	CAN1 transmit/receive FIFO receive completion interrupt	258	—
INTRCANmTRX (m = 1)	CAN1 transmit interrupt	260	—

21.1.5 I/O signals

Table 21.8 lists the I/O pins of the RS-CAN module.

Table 21.8 I/O Pins of the RS-CAN Module

Unit Signal Name	Outline	Alternative port pin signal
	CAN0	
CANmRX (m = 0)	CAN0 receive data input	CAN0RX
CANmTX (m = 0)	CAN0 transmit data output	CAN0TX
	CAN1	
CANmRX (m = 1)	CAN1 receive data input	CAN1RX
CANmTX (m = 1)	CAN1 transmit data output	CAN1TX

21.2 Function

This LSI incorporates one unit of the CAN interface (RS-CAN) which consists of two channels (CAN0 and CAN1) of the CAN controller conforming to the ISO11898-1 specifications. Table 21.9 shows the RSCAN module specifications.

Figure 21.1 shows the RS-CAN module block diagram.

Table 21.9 RS-CAN Module Specifications (1/2)

Item	Specification
Number of channels	2
Protocol	ISO11898-1 compliant
Communication speed	• Maximum 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ $\text{CANm bit time} = \text{CANmTq} \times \text{Tq count per bit}$ $\text{CANmTq} = \frac{\text{(BRP[9:0] bits in the RSCAN0CmCFG register + 1)}}{\text{fCAN}}$ m = 0 or 1 Tq: Time quantum fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCAN0GCFG register)
Buffer	160 buffers in total • Individual buffers: 32 buffers (16 buffers × 2 channels) Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel • Shared buffers: 128 buffers for all channels Receive buffer: 0 to 31 buffers Receive FIFO buffer: 8 FIFO buffers (up to 96 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 96 buffers allocatable to each)
Reception function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (CAN mode receives its own transmitted messages.) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive messages according to 128 receive rules. • Sets the number of receive rules (0 to 128) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Sets DLC check value for each acceptance rule.
Receive message transfer function	• Routing function to transfer receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit messages at intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.

Table 21.9 RS-CAN Module Specifications (2/2)

Item	Specification
Transmit history function	Stores the history information of transmitted messages.
Gateway function	A received message is automatically routed to a different channel.
Bus off recovery mode selection	Selects the method for returning from bus off state. • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel standby mode by program request • Transition to the error-active state by program request
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	8 sources • Global Interrupts [2 sources: common among channels] Receive FIFO interrupt [1 source: common among channels] Global error interrupt [1 source: common among channels] • Channel interrupts [6 sources: 3 sources × number of channels] CANm transmit interrupt [1 source for each channel] – CANm transmit complete interrupt – CANm transmit abort interrupt – CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) – CANm transmit history interrupt – CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) [1 source for each channel] CANm error interrupt [1 source for each channel] (m = 0 or 1)
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CAN module.
CAN clock source	Selects the clkc or the clk_xincan. As for the range of operating frequency, refer to Table 21.6.
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Inter-channel communication test

21.3 Registers

Table 21.10 lists the registers of the RS-CAN module.n = 0, 1.

Table 21.10 List of RS-CAN Module Registers (1/12)

Register Name	Symbol	After Reset	Address	Access Size
Channel 0 configuration register	RSCAN0C0CFG	0000 0000_H	<RSCAN0_base> + 0000_H	8, 16, 32
Channel 0 control register	RSCAN0C0CTR	0000 0005_H	<RSCAN0_base> + 0004_H	8, 16, 32
Channel 0 status register	RSCAN0C0STS	0000 0005_H	<RSCAN0_base> + 0008_H	8, 16, 32
Channel 0 error flag register	RSCAN0C0ERFL	0000 0000_H	<RSCAN0_base> + $000C_H$	8, 16, 32
Channel 1 configuration register	RSCAN0C1CFG	0000 0000_H	<RSCAN0_base> + 0010_H	8, 16, 32
Channel 1 control register	RSCAN0C1CTR	0000 0005_H	<RSCAN0_base> + 0014_H	8, 16, 32
Channel 1 status register	RSCAN0C1STS	0000 0005_H	<RSCAN0_base> + 0018_H	8, 16, 32
Channel 1 error flag register	RSCAN0C1ERFL	0000 0000_H	<RSCAN0_base> + $001C_H$	8, 16, 32
Global configuration register	RSCAN0GCFG	0000 0000_H	<RSCAN0_base> + 0084_H	8, 16, 32
Global control register	RSCAN0GCTR	0000 0005_H	<RSCAN0_base> + 0088_H	8, 16, 32
Global status register	RSCAN0GSTS	0000 $000D_H$	<RSCAN0_base> + $008C_H$	8, 16, 32
Global error flag register	RSCAN0GERFL	0000 0000_H	<RSCAN0_base> + 0090_H	8, 16, 32
Global timestamp counter register	RSCAN0GTSC	0000 0000_H	<RSCAN0_base> + 0094_H	16, 32
Receive rule entry control register	RSCAN0GAFLECTR	0000 0000_H	<RSCAN0_base> + 0098_H	8, 16, 32
Receive rule configuration register 0	RSCAN0GAFLCFG0	0000 0000_H	<RSCAN0_base> + $009C_H$	8, 16, 32
Receive buffer number register	RSCAN0RMNB	0000 0000_H	<RSCAN0_base> + $00A4_H$	8, 16, 32
Receive buffer new data register 0	RSCAN0RMND0	0000 0000_H	<RSCAN0_base> + $00A8_H$	8, 16, 32
Receive FIFO buffer configuration and control register 0	RSCAN0RFCC0	0000 0000_H	<RSCAN0_base> + $00B8_H$	8, 16, 32
Receive FIFO buffer configuration and control register 1	RSCAN0RFCC1	0000 0000_H	<RSCAN0_base> + $00BC_H$	8, 16, 32
Receive FIFO buffer configuration and control register 2	RSCAN0RFCC2	0000 0000_H	<RSCAN0_base> + $00C0_H$	8, 16, 32
Receive FIFO buffer configuration and control register 3	RSCAN0RFCC3	0000 0000_H	<RSCAN0_base> + $00C4_H$	8, 16, 32
Receive FIFO buffer configuration and control register 4	RSCAN0RFCC4	0000 0000_H	<RSCAN0_base> + $00C8_H$	8, 16, 32
Receive FIFO buffer configuration and control register 5	RSCAN0RFCC5	0000 0000_H	<RSCAN0_base> + $00CC_H$	8, 16, 32
Receive FIFO buffer configuration and control register 6	RSCAN0RFCC6	0000 0000_H	<RSCAN0_base> + $00D0_H$	8, 16, 32
Receive FIFO buffer configuration and control register 7	RSCAN0RFCC7	0000 0000_H	<RSCAN0_base> + $00D4_H$	8, 16, 32
Receive FIFO buffer status register 0	RSCAN0RFSTS0	0000 0001_H	<RSCAN0_base> + $00D8_H$	8, 16, 32
Receive FIFO buffer status register 1	RSCAN0RFSTS1	0000 0001_H	<RSCAN0_base> + $00DC_H$	8, 16, 32
Receive FIFO buffer status register 2	RSCAN0RFSTS2	0000 0001_H	<RSCAN0_base> + $00E0_H$	8, 16, 32
Receive FIFO buffer status register 3	RSCAN0RFSTS3	0000 0001_H	<RSCAN0_base> + $00E4_H$	8, 16, 32
Receive FIFO buffer status register 4	RSCAN0RFSTS4	0000 0001_H	<RSCAN0_base> + $00E8_H$	8, 16, 32
Receive FIFO buffer status register 5	RSCAN0RFSTS5	0000 0001_H	<RSCAN0_base> + $00EC_H$	8, 16, 32
Receive FIFO buffer status register 6	RSCAN0RFSTS6	0000 0001_H	<RSCAN0_base> + $00F0_H$	8, 16, 32
Receive FIFO buffer status register 7	RSCAN0RFSTS7	0000 0001_H	<RSCAN0_base> + $00F4_H$	8, 16, 32
Receive FIFO buffer pointer control register 0	RSCAN0RFPCTR0	—	<RSCAN0_base> + $00F8_H$	8, 16, 32
Receive FIFO buffer pointer control register 1	RSCAN0RFPCTR1	—	<RSCAN0_base> + $00FC_H$	8, 16, 32

15 to 10	Reserved	These bits are always read as 0. The write value should always be 0.
9 to 0	BRP[9:0]	Prescaler Division Ratio Set When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

Modify the RSCAN0CmCFG register in channel reset mode or channel halt mode. Set this register before requesting a transition to channel communication mode or channel wait mode. For a description of the bit timing parameters and settings, see Section 21.10.1, Initial Settings.

SJW[1:0] Bits

These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive.
Set a value less than or equal to the value of the TSEG2 bits.

TSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase buffer segment 2 (PHASE_SEG2). Allowed values are 2 Tq to 8 Tq, inclusive.
Set a value smaller than the value of the TSEG1 bits.

TSEG1[3:0] Bits

These bits are used to specify a Tq value for the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1).
Allowed values are 4 Tq to 16 Tq, inclusive.

BRP[9:0] Bits

The CANmTq (fCANTQm) clock is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler, ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 Time Quantum (Tq).

21.3.2 RSCAN0CmCTR — Channel Control Register (m = 0 or 1)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0004_H + (m * 0010_H)

Initial value: 0000 0005_H

Table 21.16 RSCAN0CmCTR register contents (1/2)

Bit Position	Bit Name	Function
31 to 27	Reserved	These bits are always read as 0. The write value should always be 0.
26, 25	CTMS[1:0]	Communication Test Mode Select b26 b25 0 0: Standard test mode 0 1: Listen-only mode 1 0: Self-test mode 0 (external loopback mode) 1 1: Self-test mode 1 (internal loopback mode)
24	CTME	Communication Test Mode Enable 0: Communication test mode is disabled. 1: Communication test mode is enabled.
23	ERRD	Error Display Mode Select 0: Error flags are displayed only for the first error information after bits 14 to 8 in RSCAN0CmERFL are all cleared. 1: Error flags for all error information are displayed.
22, 21	BOM[1:0]	Bus Off Recovery Mode Select b22 b21 0 0: ISO11898-1 compliant 0 1: Entry to channel halt mode automatically at bus-off entry 1 0: Entry to channel halt mode automatically at bus-off end 1 1: Entry to channel halt mode (during bus-off recovery period) by program request
20 to 17	Reserved	These bits are always read as 0. The write value should always be 0.
16	TAIE	Transmit Abort Interrupt Enable 0: Transmit abort interrupt is disabled. 1: Transmit abort interrupt is enabled.
15	ALIE	Arbitration Lost Interrupt Enable 0: Arbitration lost interrupt is disabled. 1: Arbitration lost interrupt is enabled.
14	BLIE	Bus Lock Interrupt Enable 0: Bus lock interrupt is disabled. 1: Bus lock interrupt is enabled.
13	OLIE	Overload Frame Transmit Interrupt Enable 0: Overload frame transmit interrupt is disabled. 1: Overload frame transmit interrupt is enabled.
12	BORIE	Bus Off Recovery Interrupt Enable 0: Bus off recovery interrupt is disabled. 1: Bus off recovery interrupt is enabled.

Table 21.16 RSCAN0CmCTR register contents (2/2)

Bit Position	Bit Name	Function
11	BOEIE	Bus Off Entry Interrupt Enable 0: Bus off entry interrupt is disabled. 1: Bus off entry interrupt is enabled.
10	EPIE	Error Passive Interrupt Enable 0: Error passive interrupt is disabled. 1: Error passive interrupt is enabled.
9	EWIE	Error Warning Interrupt Enable 0: Error warning interrupt is disabled. 1: Error warning interrupt is enabled.
8	BEIE	Bus Error Interrupt Enable 0: Bus error interrupt is disabled. 1: Bus error interrupt is enabled.
7 to 4	Reserved	These bits are always read as 0. The write value should always be 0.
3	RTBO	Forcible Return from Bus-off When this bit is set to 1, forcible return from the bus off state is made. This bit is always read as 0.
2	CSLPR	Channel Stop Mode 0: Other than channel stop mode 1: Channel stop mode
1, 0	CHMDC[1:0]	Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode only. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify these bits in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control the display mode of bits 14 to 8 in the RSCAN0CmERFL register.
When this bit is clear to 0, only the flags of the first error are set to 1. If two or more errors occur in the first error, all the flags of the detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.

Modify this bit only in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select the bus off recovery mode of the RS-CAN module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CAN module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CAN module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CAN module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCAN0CmCTR register (m = 0 or 1) are set to 10_B and the RS-CAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are cleared to 00_H.

When the RS-CAN module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CAN module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CAN module is in the bus off state, the RS-CAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CAN module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

If the CPU requests a transition to channel reset mode at the same time as the RS-CAN module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), the CPU's request takes precedence. Modify the BOM bits only in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode.

ALIE Bit

When the ALF flag in the RSCAN0CmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BLIE Bit

When the BLF flag in the RSCAN0CmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

OLIE Bit

When the OVLF flag in the RSCAN0CmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BORIE Bit

When the BORF flag in the RSCAN0CmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCAN0CmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EPIE Bit

When the EPF flag in the RSCAN0CmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EWIE Bit

When the EWF flag in the RSCAN0CmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BEIE Bit

When the BEF flag in the RSCAN0CmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

RTBO Bit

Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register to 00_H and also clears the BOSTS flag in the RSCAN0CmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCAN0CmCTR register are 00_B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RSCAN module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel into channel stop mode.

Clearing this bit to 0 makes the channel exit channel stop mode.

Modify this bit from 0 to 1 only in channel reset mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see Section 21.5.2, Channel Modes. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to 11_B. When the CAN module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become 10_B.

21.3.3 RSCAN0CmSTS — Channel Status Register (m = 0 or 1)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0008_H + (m * 0010_H)

Initial value: 0000 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TEC[7:0]								REC[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	COMSTS	RECSTS	TRMSTS	BOSTS	EPSTS	CSLPSTS	CHLTSTS	CRSTSTS
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.17 RSCAN0CmSTS register contents

Bit Position	Bit Name	Function
31 to 24	TEC[7:0]	The transmit error counter (TEC) can be read.
23 to 16	REC[7:0]	The receive error counter (REC) can be read.
15 to 8	Reserved	These bits are always read as 0.
7	COMSTS	Communication Status Flag 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission or bus off state 1: In reception
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	Bus Off Status Flag 0: Not in bus off state 1: In bus off state
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state
2	CSLPSTS	Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode
1	CHLTSTS	Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode

TEC[7:0] Bits

These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

COMSTS Flag

This bit indicates that communication is ready.

This flag becomes 1 when the CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the bus off state (TEC[7:0] > 255) is entered. It is cleared to 0 when the CAN module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the RS-CAN module has entered the error passive state ((128 ≤ TEC[7:0] ≤ 255) or (128 ≤ REC[7:0])), It is cleared to 0 when the RS-CAN module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel stop mode, and is cleared to 0 when the CAN module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel halt mode, and is cleared to 0 when the CAN module has returned from channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel reset mode, and is cleared to 0 when the CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the CAN module transitions from channel reset mode to channel stop mode.

21.3.4 RSCAN0CmERFL — Channel Error Flag Register (m = 0 or 1)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $000C_H$ + (m * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	CRCREG[14:0]														
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	ADERR	B0ERR	B1ERR	CERR	AERR	FERR	SERR	ALF	BLF	OVLF	BORF	BOEF	EPF	EWF	BEF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.18 RSCAN0CmERFL register contents (1/2)

Bit Position	Bit Name	Function
31	Reserved	This bit is always read as 0. The write value should always be 0.
30 to 16	CRCREG[14:0]	CRC Calculation Data A CRC value calculated based on the transmit message or receive message is indicated.
15	Reserved	This bit is always read as 0. The write value should always be 0.
14	ADERR	ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	Form Error Flag 0: No form error is detected. 1: Form error is detected.
8	SERR	Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	Arbitration-lost Flag 0: No arbitration-lost is detected. 1: Arbitration-lost is detected.
6	BLF	Dominant Lock Flag 0: No dominant lock is detected. 1: Dominant lock is detected.

Table 21.18 RSCAN0CmERFL register contents (2/2)

Bit Position	Bit Name	Function
5	OVLF	Overload Flag 0: No overload is detected. 1: Overload is detected.
4	BORF	Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	Error Passive Flag 0: No error passive is detected. 1: Error passive is detected.
1	EWF	Error Warning Flag 0: No error warning is detected. 1: Error warning is detected.
0	BEF	Protocol Error Flag 0: No protocol error is detected. 1: Protocol error is detected.

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these error occurs at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0. If the ERRD bit in the RSCAN0CmCTR register is set to 0 (ie, only the flags from the first error event are displayed) and an error related to bits 14 to 8 of RSCAN0CmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the time the error occurred.

CRCREG[14:0] Flag

When the CTME bit in the RSCAN0CmCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmit or receive message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration-lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, dominant lock can be detected again if any of the following conditions is met.

- a recessive bit is detected after the BLF bit has been cleared from 1 to 0.
- the CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0.

OVLF Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the CAN module returns from the bus off state. However, this flag is not set to 1 if the CAN module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCAN0CmCTR register is set to 1 (forcible return from the bus off state is made).
- The BOM[1:0] bits in the RSCAN0CmCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCAN0CmCTR register (m = 0 or 1) set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).

This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWF Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCAN0CmERFL register is set to 1.

21.3.5 RSCAN0GCFG — Global Configuration Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0084_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.19 RSCAN0GCFG register contents (2/2)

Bit Position	Bit Name	Function
3	MME	Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	Transmit Priority Select 0: ID priority 1: Transmit buffer number priority

Note 1. When specifying CKSCLK_ICANOSC as the timestamp counter count source, set bits TSBTCS[2:0] to 000_B.

Note 2. For the setting of the CAN clock frequency, see Table 21.6, Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in this LSI.

Modify the RSCAN0GCFG register only in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. Refer to Section 21.7.3.1, Interval Transmission Function

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

TSSS Bit

This bit is used to select a clock source of the timestamp counter.

TSP[3:0] Bits

A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source.

DCS Bit

When this bit is set to 0, clkc is used as the clock source of the CAN clock (f_{CAN}).

When this bit is set to 1, clk_xincan is used as the clock source of the CAN clock (f_{CAN}).

For the setting of the CAN clock frequency, see Table 21.6, Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in this LSI.

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00_H is stored in each data byte beyond the first n bytes, where n is the DLC value of the receive rule.

The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled).

DCE Bit

Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCAN0GAFLP0j register to 0000_B before clearing the DCE bit in the RSCAN0GCFG register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those with pending messages has the highest priority.

While the transmit queue is in use, this bit should be set to 0.

21.3.6 RSCAN0GCTR — Global Control Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0088_H

Initial value: $0000\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.20 RSCAN0GCTR register contents

Bit Position	Bit Name	Function
31 to 17	Reserved	These bits are always read as 0. The write value should always be 0.
16	TSRST	Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.
15 to 11	Reserved	These bits are always read as 0. The write value should always be 0.
10	THLEIE	Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	FIFO Message Lost Interrupt Enable 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	Reserved	These bits are always read as 0. The write value should always be 0.
2	GSLPR	Global Stop Mode 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCAN0GTSC register is cleared to 0000_H.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

GSLPR Bit

When the RSCAN module is in global reset mode, setting this bit to 1 places the RSCAN module into global stop mode.

Clearing this bit to 0 makes the RSCAN module leave from global stop mode.

Modify this bit only in global reset mode.

GMDC[1:0] Bits

These bits are used to select the mode of entire RS-CAN module (global operating mode, global reset mode, or global test mode). For details, see Section 21.5.1, Global Modes. Setting the GSLPR bit to 1 when in global reset mode places the RS-CAN module into global stop mode.

21.3.7 RSCAN0GSTS — Global Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $008C_H$

Initial value: 0000 $000D_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.21 RSCAN0GSTS register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	These bits are always read as 0.
3	GRAMINIT	CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	Global Test Status Flag 0: Not in global test mode 1: In global test mode
0	GRSTSTS	Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after this LSI has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to global stop mode, and is cleared to 0 when the CAN module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global test mode, and is cleared to 0 when the CAN module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global reset mode, and is cleared to 0 when the CAN module has exited global reset mode. This flag remains 1 even when the CAN module has transitioned from global reset mode to global stop mode.

21.3.8 RSCAN0GERFL — Global Error Flag Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0090_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.22 RSCAN0GERFL register contents

Bit Position	Bit Name	Function
31 to 29	Reserved	The read value is undefined. The write value should always be 0.
2	THLES	Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred.
1	MES	FIFO Message Lost Status Flag 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred.
0	DEF	DLC Error Flag 0: No DLC error has occurred. 1: A DLC error has occurred.

All flags in the RSCAN0GERFL register are cleared to 0 in global reset mode.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCAN0THLSTSm register (m = 0 or 1) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCAN0RFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCAN0CFSTSk register (k = 0 to 5) is set to 1.

This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit.

21.3.9 RSCAN0GTINTSTS0 — Global TX Interrupt Status Register 0

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0460_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	THIF1	CFTIF1	TQIF1	TAIF1	TSIF1	—	—	—	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R*1	R*1	R*1	R*1	R*1	R	R	R	R*1	R*1	R*1	R*1	R*1

Note 1. This bit is automatically cleared in the global reset or channel reset mode.

Table 21.23 RSCAN0GTINTSTS0 register contents

Bit Position	Bit Name	Function
31 to 13	Reserved	These bits are always read as 0. The write value should always be 0.
12	THIF1	Channel 1 transmit history interrupt status flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF1	Channel 1 transmit/receive FIFO transmit/gateway mode interrupt status flag 0: Transmit/receive FIFO transmit/gateway mode interrupt is not requested. 1: Transmit/receive FIFO transmit/gateway mode interrupt is requested.
10	TQIF1	Channel 1 transmit queue interrupt status flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF1	Channel 1 transmit buffer abort interrupt status flag 0: Transmit buffer transmit abort interrupt is not requested. 1: Transmit buffer transmit abort interrupt is requested.
8	TSIF1	Channel 1 transmit buffer interrupt status flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	Reserved	These bits are always read as 0. The write value should always be 0.
4	THIF0	Channel 0 transmit history interrupt status flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF0	Channel 0 transmit/receive FIFO transmit/gateway mode interrupt status flag 0: Transmit/receive FIFO transmit/gateway mode interrupt is not requested. 1: Transmit/receive FIFO transmit/gateway mode interrupt is requested.
2	TQIF0	Channel 0 transmit queue interrupt status flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF0	Channel 0 transmit buffer abort interrupt status flag 0: Transmit buffer transmit abort interrupt is not requested. 1: Transmit buffer transmit abort interrupt is requested.
0	TSIF0	Channel 0 transmit buffer interrupt status flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

TSIFm Bits

The TSIFm bit is set to 1 when the TMIE bit in the RSCAN0TMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCAN0TMSTSp register are set to 10_B (transmit completed without abort request) or 11_B (transmit completed with abort request).

When the TMTRF[1:0] flags are cleared to 00_B under the condition that the TSIFm bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIE bit to 0 also clears this flag to 0.

TAIFm Bits

The TAIFm bit is set to 1 when the TAIE bit in the RSCAN0CmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCAN0TMSTSp register are set to 01_B (transmit abort completed).

This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to 00_B after the transmit abort is completed.

TQIFm Bits

When the TXQIE bit in the RSCAN0TXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCAN0TXQSTSm register is set to 1 (transmit queue interrupt request), the TQIFm bit is set to 1.

When the TXQIF bit (transmit queue interrupt request) in the RSCAN0TXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0.

CFTIFm Bits

When the CFTXIE bit in the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO buffer transmit interrupt enabled) and the CFTXIF bit in the RSCAN0CFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), the CFTIFm bit is set to 1.

When the CFTXIF bit is cleared to 0 under the condition that the CFTIFm bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0.

THIFm Bits

When the THLIE bit in the RSCAN0THLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCAN0THLSTSm register is set to 1 (transmit history interrupt request), the THIFm bit is set to 1.

When the THLIF bit in the RSCAN0THLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0.

21.3.10 RSCAN0GTSC — Global Timestamp Counter Register

Access: Can be read in 8-, 16- and 32-bit units

Address: <RSCAN0_base> + 0094_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.24 RSCAN0GTSC register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0.
15 to 0	TS[15:0]	Timestamp Value The timestamp counter value can be read. Counter Value: 0000_H to $FFFF_H$

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. The timestamp counter is initialized in global reset mode.

The timestamp counter starts and stops counting differently, depending on the count source.

- When the TSSS bit in the RSCAN0GCFG register is 0 (pclk):
  The timestamp counter starts counting when the RSCAN module has transitioned to global operating mode.
  This counter stops counting when the RSCAN module has transitioned to global stop mode or global test mode.
- When the TSSS bit is 1 (CANm bit time clock):
  The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode.
  This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

21.3.11 RSCAN0GAFLECTR — Receive Rule Entry Control Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0098_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	AFLDAE	—	—	—	AFLPN[4:0]				
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 21.25 RSCAN0GAFLECTR register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	These bits are always read as 0. The write value should always be 0.
8	AFLDAE	Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	Reserved	These bits are always read as 0. The write value should always be 0.
4 to 0	AFLPN[4:0]	Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (00000_B) to page 7 (00111_B).

AFLDAE Bit

Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 only in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within the range of 00000_B to 00111_B.

21.3.12 RSCAN0GAFLCFG0 — Receive Rule Configuration Register 0

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $009C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RNC0[7:0]								RNC1[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.26 RSCAN0GAFLCFG0 register contents

Bit Position	Bit Name	Function
31 to 24	RNC0[7:0]	Number of Rules for Channel 0 Set the number of receive rules exclusively used for channel 0.
23 to 16	RNC1[7:0]	Number of Rules for Channel 1 Set the number of receive rules exclusively used for channel 1.
15 to 0	Reserved	These bits are always read as 0. The write value should always be 0.

Modify the RSCAN0GAFLCFG0 register only in global reset mode.

Up to 64 x (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

21.3.13 RSCAN0GAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0500_H + (j * 0010_H)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLID[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.27 RSCAN0GAFLIDj register contents

Bit Position	Bit Name	Function
b31	GAFLIDE	IDE Select 0: Standard ID 1: Extended ID
b30	GAFLRTR	RTR Select 0: Data frame 1: Remote frame
b29	GAFLLB	Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received
b28 to b0	GAFLID[28:0]	ID Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0.

Modify the RSCAN0GAFLIDj register when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node.

When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing.

21.3.14 RSCAN0GAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0504_H + (j * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDEM	GAFLRTRM	—	GAFLIDM[28:16]												
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLIDM[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.28 RSCAN0GAFLMj register contents

Bit Position	Bit Name	Function
31	GAFLIDEM	IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared
29	Reserved	This bit is always read as 0. The write value should always be 0.
28 to 0	GAFLIDM[28:0]	ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCAN0GAFLMj register when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCAN0GAFLIDj register.

When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bit of the receive rule.

21.3.15 RSCAN0GAFLP0j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0508_H + (j * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLDLC[3:0]				GAFLPTR[11:0]											
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.29 RSCAN0GAFLP0j register contents

Bit Position	Bit Name	Function
31 to 28	GAFLDLC[3:0]	Receive Rule DLC b31 b30 b29 b28 0 0 0 0: DLC check is disabled. 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	GAFLPTR[11:0]	Receive Rule Label Set the 12-bit label information.
15	GAFLRMV	Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP[6:0]	Receive Buffer Number Select Set the receive buffer number to store receive messages.
7 to 0	Reserved	These bits are always read as 0. The write value should always be 0.

Modify the RSCAN0GAFLP0j register when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCAN0RMNB register.

21.3.16 RSCAN0GAFLP1j — Receive Rule Pointer 1 Register (j = 0 to 15)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $050C_H$ + (j * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.30 RSCAN0GAFLP1j register contents

Bit Position	Bit Name	Function
31 to 14	Reserved	These bits are always read as 0. The write value should always be 0.
13 to 0	GAFLFDP [13:0]	FIFO Buffer z Select (z = 0 to 13) z = 0 to 7 0: Receive FIFO buffer z is not selected. 1: Receiver FIFO buffer z is selected. z = 8 to 13 0: Transmit/receive FIFO buffer z-8 is not selected. 1: Transmit/receive FIFO buffer z-8 is selected.

Modify the RSCAN0GAFLP1j register when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP [13:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCAN0GAFLP0j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected.

Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCAN0CFCCk register are set to 00_B (receive mode) or 10_B (gateway mode) are selectable.

21.3.17 RSCAN0RMNB — Receive Buffer Number Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $00A4_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.31 RSCAN0RMNB register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are always read as 0. The write value should always be 0.
7 to 0	NRXMB[7:0]	Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 31.

Modify the RSCAN0RMNB register only in global reset mode.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the RS-CAN module. The maximum value is 16 × (number of channels).

Setting these bits all to 0 makes receive buffers unavailable.

21.3.18 RSCAN0RMNDy — Receive Buffer New Data Register y (y = 0)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $00A8_H$ + (y * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMNSq (q = y × 32 + 31 to y × 32 + 16 (y = 0))

Table 21.32 RSCAN0RMNDy register contents

Bit Position	Bit Name	Function
31 to 16	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.
15 to 0	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.

Write 0 to the RSCAN0RMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 31)

Each RMNS flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. It takes ten clock cycles of pclk to store a message.

These flags are cleared to 0 in global reset mode.

21.3.19 RSCAN0RMIDq — Receive Buffer ID Register (q = 0 to 31)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0600_H + (q * 0010_H)

Initial value: $0000\ 0000_H$

Bit Position	Bit Name	Function
31	RMIDE	Receive Buffer IDE 0: Standard ID 1: Extended ID
30	RMRTR	Receive Buffer RTR 0: Data frame 1: Remote frame
29	Reserved	This bit is always read as 0.
28 to 0	RMID[28:0]	Receive Buffer ID Data These bits contain the standard ID or extended ID of the received message. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer.

RMID[28:0] Bits

These bits contain the ID of the message stored in the receive buffer.

21.3.20 RSCAN0RMPTRq — Receive Buffer Pointer Register (q = 0 to 31)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0604_H + (q * 0010_H)

Initial value: 0000 0000_H

Table 21.34 RSCAN0RMPTRq

Bit Position	Bit Name	Function
31 to 28	RMDLC[3:0]	Receive Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	RMPTR[11:0]	Receive Buffer Label Data Label information of the received message.
15 to 0	RMTS[15:0]	Receive Buffer Timestamp Data Timestamp value of the received message.

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

21.3.21 RSCAN0RMDF0q — Receive Buffer Data Field 0 Register (q = 0 to 31)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0608_H + (q * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.37 RSCAN0RFCCx register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0. The write value should always be 0.
15 to 13	RFIGCV[2:0]	Receive FIFO Interrupt Request Timing Select b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full.
12	RFIM	Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	Reserved	This bit is always read as 0. The write value should always be 0.
10 to 8	RFDC[2:0]	Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages
7 to 2	Reserved	These bits are always read as 0. The write value should always be 0.
1	RFIE	Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

RFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B (fractions which are even multiples of 1/4). Modify these bits only in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to 000_B, no receive FIFO buffer should be used. Modify these bits only in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCAN0RFSTSx register to 1 (the receive FIFO buffer contains no unread message (buffer empty)). Modify this bit in global operating mode or global test mode.

21.3.24 RSCAN0RFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $00D8_H$ + (x * 0004_H)

Initial value: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.38 RSCAN0RFSTSx register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0. The write value should always be 0.
15 to 8	RFMC[7:0]	Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed.
7 to 4	Reserved	These bits are always read as 0. The write value should always be 0.
3	RFIF	Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.
2	RFMLT	Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty).

RFMC[7:0] Flag

This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes 00_H when the RFE bit in the RSCAN0RFCCx register is set to 0.

RFIF Flag

This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCAN0RFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

RFMLT Flag

This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCAN0RFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCAN0RFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCAN0RFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

21.3.25 RSCAN0RFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7)

Access: Can be written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $00F8_H$ + (x * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 21.39 RSCAN0RFPCTRx register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should always be 0.
7 to 0	RFPC[7:0]	Receive FIFO Pointer Control When these bits are set to FF_H, the read pointer moves to the next unread message in the receive FIFO buffer.

RFPC[7:0] Bits

When the RFPC[7:0] bits are set to FF_H, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCAN0RFSTSx register is decremented. Read the RSCAN0RFID, RSCAN0RFPTR, RSCAN0RFDF0, and RSCAN0RFDF1 registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

Write FF_H to these bits when the RFE bit in the RSCAN0RFCCx register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCAN0RFSTSx register is 0 (the receive FIFO buffer contains unread messages).

21.3.26 RSCAN0RFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $0E00_H$ + (x * 0010_H)

Initial value: $0000\ 0000_H$

30	RFRTR	Receive FIFO Buffer RTR 0: Data frame 1: Remote frame
29	Reserved	This bit is always read as 0.
28 to 0	RFID[28:0]	Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

21.3.27 RSCAN0RFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $0E04_H$ + (x * 0010_H)

Initial value: $0000\ 0000_H$

15 to 0	RFTS[15:0]	Receive FIFO Buffer Timestamp Data Timestamp value of the received message can be read.

RFDLC[3:0] Bits

These bits contain the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits contain the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits contain the timestamp value of the message stored in the receive FIFO buffer.

21.3.28 RSCAN0RFDF0x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $0E08_H$ + (x * 0010_H)

Initial value: 0000 0000_H

Table 21.44 RSCAN0CFCCk register contents (2/2)

Bit Position	Bit Name	Function
b12	CFIM	Transmit/Receive FIFO Interrupt Source Select 0: • Receive mode/gateway mode When the number of received messages has met the condition set by the CFIGCV[2:0] bits, a FIFO receive interrupt request is generated. • Transmit mode/gateway mode When the buffer becomes empty upon completion of message transmission, a FIFO transmit interrupt request is generated. 1: • Receive mode/gateway mode A FIFO receive interrupt request is generated each time a message has been received. • Transmit mode/gateway mode A FIFO transmit interrupt request is generated each time a message has been transmitted.
b11	Reserved	This bit is always read as 0. The write value should always be 0.
b10 to b8	CFDC[2:0]	Transmit/Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages
b7 to b3	Reserved	These bits are always read as 0. The write value should always be 0.
b2	CFTXIE	Transmit/Receive FIFO Transmit Interrupt Enable 0: Transmit/receive FIFO transmit interrupt is disabled. 1: Transmit/receive FIFO transmit interrupt is enabled.
b1	CFRXIE	Transmit/Receive FIFO Receive Interrupt Enable 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled.
b0	CFE	Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

CFITT[7:0] Bits

These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as m = k/3 (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be ((16 × m) + CFTML[3:0]).

Refer to Table 21.11 and Table 21.12, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p.

Setting the CFDC[2:0] bits to 001_B or more enables the setting of the CFTML[3:0] bits.

Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 1.

When this bit is 0, the interval timer clock source is the pclk/2 clock divided by the value of the ITRCP[15:0] bits in the RSCAN0GCFG register.

When this bit is 1, the interval timer clock source is the pclk/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCAN0GCFG register × 10).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.

When this bit is 1, the bit time clock of the channel to which the FIFO is linked is the count source of the interval timer.

CFM[1:0] Bits

These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode.

CFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00_B (receive mode) or 10_B (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).

An interrupt request is generated when the number of stored messages reaches the specified ratio (in fraction) of the storable messages set with the CFDC[2:0] bits.

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B, 011_B, 101_B, or B'111.

Modify these bits only in global reset mode.

CFIM Bit

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode.

CFDC[2:0] Bits

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to 000_B, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFTXIE Bit

When this bit is set to 1 and the CFTXIF flag in the RSCAN0CFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CFRXIF flag in the RSCAN0CFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode
  Modify this bit in the following mode.
- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

21.3.31 RSCAN0CFSTSk — Transmit/receive FIFO buffer Status Register (k = 0 to 5)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0178_H + (k * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.45 RSCAN0CFSTSk register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0. The write value should always be 0.
15 to 8	CFMC[7:0]	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer.
7 to 5	Reserved	These bits are always read as 0. The write value should always be 0.
4	CFTXIF	Transmit/Receive FIFO Transmit Interrupt Request Flag 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.
3	CFRXIF	Transmit/Receive FIFO Receive Interrupt Request Flag 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.
2	CFMLT	Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFFLL	Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.
0	CFEMP	Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCAN0CFCCk register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: In global reset mode
- When CFM[1:0] value is 01_B or 10_B: In channel reset mode

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 01_B or 10_B, and the factor selected by the CFIM bit in the RSCAN0CFCCk register occurs

The CFTXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFTXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B, and the factor selected by the CFIM bit in the RSCAN0CFCCk register occurs

The CFRXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFRXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFMLT flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode

- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode

CFFLL Flag

The CFFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCAN0CFCCk register.

The CFFLL flag is cleared to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits.
- When the CFE bit in the RSCAN0CFCCk register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B: All messages have been read, or in global reset mode
- When the CFM[1:0] bits are set to 01_B: All messages have been transmitted, or in channel reset mode
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B: At least one received message has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] bits are set to 01_B or 10_B: A value of FF_H has been written to the RSCAN0CFPCTRk register after data was written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers.

21.3.32 RSCAN0CFPCTRk — Transmit/receive FIFO buffer Pointer Control Register (k = 0 to 5)

Access: Can be written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $01D8_H$ + (k * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 21.46 RSCAN0CFPCTRk register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should always be 0.
7 to 0	CFPC[7:0]	Transmit/Receive FIFO Pointer Control • Receive mode: Writing FF_H to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. • Transmit mode: Writing FF_H to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. • Gateway mode: Setting prohibited

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCAN0CFCCk register is 00_B):
  Writing FF_H to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCAN0CFSTSk register is decremented. Read the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers to read messages from the transmit/receive FIFO buffer, and then write FF_H to the CFPC[7:0] bits.
  Write FF_H to these bits when the CFE bit in the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCAN0CFSTSk register is cleared to 0 (the transmit/receive FIFO buffer contains messages).

- Transmit mode (CFM[1:0] value in the RSCAN0CFCCk register is 01_B):
  Writing FF_H to the CFPC[7:0] bits stores the data written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers before writing FF_H to the CFPC[7:0] bits.
  Write FF_H to these bits when the CFE bit in the RSCAN0CFCCk register is set to 1 and the CFFLL flag in the RSCAN0CFSTSk register is cleared to 0 (the transmit/receive FIFO buffer is not full).
- Gateway mode (CFM[1:0] value in the RSCAN0CFCCk register is 10_B):
  Setting prohibited

21.3.33 RSCAN0CFIDk — Transmit/receive FIFO buffer Access ID Register (k = 0 to 5)

Access: Can be read/written in 8-, 16-, and 32-bit units

Bit Position	Bit Name	Function
b31	CFIDE	Transmit/Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID
b30	CFRTR	Transmit/Receive FIFO Buffer RTR 0: Data frame 1: Remote frame
b29	THLEN	Transmit History Data Store Enable This bit is valid only when the CFM[1:0] value is 01_B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
b28 to b0	CFID[28:0]	Transmit/Receive FIFO Buffer ID Data • When CFM[1:0] value is B'01 (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits b10 to b0 and write 0 to bits b28 to b11. • When CFM[1:0] value is B'00 (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits b10 to b0. Bits b28 to b11 are read as 0.

This register is writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This RSCAN0CFIDk register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, these bits are used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

This bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, this bit is used to set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, and buffer type) of transmit messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits contain the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is B'01, this bit is used to set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

21.3.34 RSCAN0CFPTRk — Transmit/receive FIFO buffer Access Pointer Register (k = 0 to 5)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $0E84_H$ + (k * 0010_H)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDLC[3:0]				CFPTR[11:0]

Table 21.48 RSCAN0CFPTRk register contents

Bit Position	Bit Name	Function
b31 to b28	CFDLC[3:0]	Transmit/Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
b27 to b16	CFPTR[11:0]	Transmit/Receive FIFO Buffer Label Data • When CFM[1:0] value is 01_B (transmit mode): Set the label information to be stored in the transmit history buffer. Only bits CFPTR[7:0] are valid. • When CFM[1:0] value is 00_B (receive mode): The label information of the received message can be read.
b15 to b0	CFTS[15:0]	Transmit/Receive FIFO Buffer Timestamp Data These bits are valid only when the CFM[1:0] value is B'00 (receive mode). The timestamp value of the received message can be read.

This register is writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, these bits are used to set the data length of the message to be transmitted from the transmit/receive FIFO buffer. If the data length is set to 9 bytes or more, the actual transmit data defaults to 8 bytes.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

21.3.35 RSCAN0CFDF0k — Transmit/receive FIFO buffer Access Data Field 0 Register (k = 0 to 5)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $0E88_H$ + (k * 0010_H)

Initial value: $0000\ 0000_H$

Table 21.51 RSCAN0FESTS register contents

Bit Position	Bit Name	Function
31 to 23	Reserved	These bits are always read as 0.
22 to 14	Reserved	These bits are always read as 1.
13	CF5EMP	Transmit/Receive FIFO Buffer Empty Status Flag 0: Transmit/receive FIFO buffer k contains a message. 1: Transmit/receive FIFO buffer k contains no message. (k = 0 to 5)
12	CF4EMP	
11	CF3EMP	
10	CF2EMP	
9	CF1EMP	
8	CF0EMP	
7	RF7EMP	Receive FIFO Buffer Empty Status Flag 0: Receive FIFO buffer x contains an unread message. 1: Receive FIFO buffer x contains no unread message (buffer empty). (x = 0 to 7)
6	RF6EMP	
5	RF5EMP	
4	RF4EMP	
3	RF3EMP	
2	RF2EMP	
1	RF1EMP	
0	RF0EMP	

The RSCAN0FESTS register is set to 007F $FFFF_H$ in global reset mode.

CFkEMP Flag (k = 0 to 5)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCAN0RFSTSx register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

21.3.38 RSCAN0FFSTS — FIFO Full Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $023C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.52 RSCAN0FFSTS register contents

Bit Position	Bit Name	Function
31 to 14	Reserved	These bits are always read as 0.
13	CF5FLL	Transmit/Receive FIFO Buffer Full Status Flag 0: Transmit/receive buffer k is not full. 1: Transmit/receive buffer k is full. (k = 0 to 5)
12	CF4FLL	
11	CF3FLL	
10	CF2FLL	
9	CF1FLL	
8	CF0FLL	
7	RF7FLL	Receive FIFO Buffer Full Status Flag 0: Receive FIFO buffer x is not full. 1: Receive FIFO buffer x is full. (x = 0 to 7)
6	RF6FLL	
5	RF5FLL	
4	RF4FLL	
3	RF3FLL	
2	RF2FLL	
1	RF1FLL	
0	RF0FLL	

The RSCAN0FFSTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkFLL Flag (k = 0 to 5)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer is full). When the CFFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full), the CFkFLL flag is cleared to 0.

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCAN0RFSTSx register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLL flag is cleared to 0.

21.3.39 RSCAN0FMSTS — FIFO Message Lost Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0240_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.53 RSCAN0FMSTS register contents

Bit Position	Bit Name	Function
31 to 14	Reserved	These bits are always read as 0.
13	CF5MLT	Transmit/Receive FIFO Buffer Message Lost Status Flag 0: No transmit/receive FIFO buffer k message is lost. 1: A transmit/receive FIFO buffer k message is lost. (k = 0 to 5)
12	CF4MLT	
11	CF3MLT	
10	CF2MLT	
9	CF1MLT	
8	CF0MLT	
7	RF7MLT	Receive FIFO Buffer Message Lost Status Flag 0: No receive FIFO buffer x message is lost. 1: A receive FIFO buffer x message is lost. (x = 0 to 7)
6	RF6MLT	
5	RF5MLT	
4	RF4MLT	
3	RF3MLT	
2	RF2MLT	
1	RF1MLT	
0	RF0MLT	

The RSCAN0FMSTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkMLT Flag (k = 0 to 5)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

21.3.40 RSCAN0RFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0244_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.54 RSCAN0RFISTS register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	These bits are always read as 0.
7	RF7IF	Receive FIFO Buffer Interrupt Request Status Flag 0: No receive FIFO buffer x interrupt request is present. 1: A receive FIFO buffer x interrupt request is present. (x = 0 to 7)
6	RF6IF	
5	RF5IF	
4	RF4IF	
3	RF3IF	
2	RF2IF	
1	RF1IF	
0	RF0IF	

The RSCAN0RFISTS register is cleared to $0000\ 0000_H$ in global reset mode.

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF flag is cleared to 0.

21.3.41 RSCAN0CFRISTS — Transmit/receive FIFO buffer Receive Interrupt Flag Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0248_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.55 RSCAN0CFRISTS register contents

Bit Position	Bit Name	Function
31 to 6	Reserved	These bits are always read as 0.
5	CF5RXIF	Transmit/Receive FIFO Buffer Receive Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k receive interrupt request is present. 1: A transmit/receive FIFO buffer k receive interrupt request is present. (k = 0 to 5)
4	CF4RXIF	
3	CF3RXIF	
2	CF2RXIF	
1	CF1RXIF	
0	CF0RXIF	

The RSCAN0CFRISTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkRXIF Flag (k = 0 to 5)

The CFkRXIF flag is set to 1 when the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). When the CFRXIF flag is cleared to 0, the CFkRXIF flag is cleared to 0.

21.3.42 RSCAN0CFTISTS — Transmit/receive FIFO buffer Transmit Interrupt Flag Status Register

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $024C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.56 RSCAN0CFTISTS register contents

Bit Position	Bit Name	Function
31 to 6	Reserved	These bits are always read as 0.
5	CF5TXIF	Transmit/Receive FIFO Buffer Transmit Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k transmit interrupt request is present. 1: A transmit/receive FIFO buffer k transmit interrupt request is present. (k = 0 to 5)
4	CF4TXIF	
3	CF3TXIF	
2	CF2TXIF	
1	CF1TXIF	
0	CF0TXIF	

The RSCAN0CFTISTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkTXIF Flag (k = 0 to 5)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

21.3.43 RSCAN0TMCp — Transmit Buffer Control Register (p = 0 to 31)

Access: Can be read/written in 8-bit units

Address: <RSCAN0_base> + 0250_H + (01_H × p)

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W*1	R/W*1

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Table 21.57 RSCAN0TMCp register contents

Bit Position	Bit Name	Function
7 to 3	Reserved	These bits are always read as 0. The write value should always be 0.
2	TMOM	One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested.
0	TMTR	Transmit Request 0: Transmission is not requested. 1: Transmission is requested.

When the RSCAN0TMCp register meets any of the following conditions, set it to 00_H.

- The RSCAN0TMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCAN0CFCCk register (p = m × 16 + the value of CFTML[3:0] bits).
- The RSCAN0TMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCAN0TXQCCm register (m = 0 or 1) (p = (m × 16 + 15) to (m × 16 + 15 - the value of TXQDC[3:0] bits)).

Bits in the RSCAN0TMCp register are all cleared to 0 in channel reset mode. Modify the RSCAN0TMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCAN0TMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted.

When the TMTAR bit can be set to 1 when TMTR bit is 1.

The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration loss has been detected.

If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed after the TMTAR bit was set to 1.
- An error or arbitration-lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCAN0TMSTSp register is 00_B.

21.3.44 RSCAN0TMSTSp — Transmit Buffer Status Register (p = 0 to 31)

Access: Can be read/written in 8-bit units

Address: <RSCAN0_base> + $02D0_H$ + ($01_H \times p$)

Initial value: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R

Table 21.58 RSCAN0TMSTSp register contents

Bit Position	Bit Name	Function
7 to 5	Reserved	These bits are always read as 0. The write value should always be 0.
4	TMTARM	Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present.
2, 1	TMTRF[1:0]	Transmit Buffer Transmit Result Status Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request).
0	TMTSTS	Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCAN0TMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCAN0TMCp register is set to 1.

The TMTARM flag is set to 0 when the TMTAR bit in the RSCAN0TMCp register is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCAN0TMCp register is set to 1.

The TMTRM flag is set to 0 when the TMTR bit in the RSCAN0TMCp register is set to 0

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00_B: Transmission is in progress or no transmit request is present.

01_B: Transmission from the transmit buffer was aborted.

10_B: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 0 (transmit abort is not requested).

11_B: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 1 (transmit abort is requested).

Write 00_B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00_B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost.

21.3.45 RSCAN0TMTRSTSy — Transmit Buffer Transmit Request Status Register y (y = 0)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0350_H + (y * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMTRSTSp (p = y × 32 + 31 to y × 32 + 16 (y = 0))															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.59 RSCAN0TMTRSTSy register contents

Bit Position	Bit Name	Function
31 to 16	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: No transmission is requested. 1: Transmission is requested.
15 to 0	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: No transmit request is present. 1: A transmit request is present.

TMTRSTSp Flags (p = 0 to 31)

These flags indicate the status of the TMTR bit in the RSCAN0TMCp register.

When the TMTR bit is set to 1 (transmission is requested), the corresponding TMTRSTSp flag is set to 1.

The corresponding TMTRSTSp flag is cleared to 0 when the TMTR bit is set to 0 (transmission is not requested) or in channel reset mode.

Table 21.60 shows the bit assignment.

Table 21.67 RSCAN0TMIECy register contents

Bit Position	Bit Name	Function
31 to 16	TMIEp	Transmit Buffer Interrupt Enable Bit p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled 1: Transmit buffer interrupt is enabled
15 to 0	TMIEp	Transmit Buffer Interrupt Enable Bit p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.

TMIEp Bits (p = 0 to 31)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCAN0TMSTSp register is 0 (no transmit request is present).

Write 0 to bits corresponding to transmit buffers linked to transmit/receive FIFO buffers or transmit buffers allocated to the transmit queue.

Table 21.68 shows the bit assignment.

Table 21.69 RSCAN0TMIDp register contents

Bit Position	Bit Name	Function
31	TMIDE	Transmit Buffer IDE 0: Standard ID 1: Extended ID
30	TMRTR	Transmit Buffer RTR 0: Data frame 1: Remote frame
29	THLEN	Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	TMID[28:0]	Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11.

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

THLEN Bit

When this bit is set to 1, the transmit history data of the transmit message (the label information and the number and type of the transmit buffer) are stored in the transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

21.3.51 RSCAN0TMPTRp — Transmit Buffer Pointer Register (p= 0 to 31)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 1004_H + (p * 0010_H)

Initial value: $0000\ 0000_H$

Table 21.70 RSCAN0TMPTRp register contents

Bit Position	Bit Name	Function
31 to 28	TMDLC[3:0]	Transmit Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 24	Reserved	These bits are always read as 0. The write value should always be 0.
23 to 16	TMPTR[7:0]	Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer.
15 to 0	Reserved	These bits are always read as 0. The write value should always be 0.

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCAN0TMIDp register is set to 0 (data frame). If the data length is set to 9 bytes or more, the transmit data is 8 bytes long.

When the TMRTR bit is set to 1 (remote frame), set the data length of messages to be requested.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

21.3.52 RSCAN0TMDF0p — Transmit Buffer Data Field 0 Register (p = 0 to 31)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 1008_H + (p * 0010_H)

Initial value: $0000\ 0000_H$

23 to 16	TMDB2[7:0]	
15 to 8	TMDB1[7:0]	
7 to 0	TMDB0[7:0]	

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p (p = m × 16 + 15) for the corresponding channel.

21.3.53 RSCAN0TMDF1p — Transmit Buffer Data Field 1 Register (p = 0 to 31)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $100C_H$ + (p * 0010_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.73 RSCAN0TXQCCm register contents

Bit Position	Bit Name	Function
31 to 14	Reserved	These bits are always read as 0. The write value should always be 0.
13	TXQIM	Transmit Queue Interrupt Source Select 0: When the buffer becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted.
12	TXQIE	Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.
11 to 8	TXQDC[3:0]	Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited.
7 to 1	Reserved	These bits are always read as 0. The write value should always be 0.
0	TXQE	Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used.

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.

Set the TXQE bit to 0 before modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from (m × 16 + 15) to (m × 16 + 0). For examples of how buffer allocation is done, see Figure 21.9. Modify these bits only in channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to 0010_B or more.

21.3.55 RSCAN0TXQSTSm — Transmit Queue Status Register (m = 0 or 1)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $03C0_H$ + (m * 0004_H)

Initial value: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFLL	TXQEMP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.74 RSCAN0TXQSTSm register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	The read value is undefined. The write value should always be 0.
2	TXQIF	Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.
1	TXQFLL	Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

TXQIF Flag

The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCAN0TXQCCm register has occurred.

The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCAN0TXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCAN0TXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is pending in the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

21.3.56 RSCAN0TXQPCTRm — Transmit Queue Pointer Control Register (m = 0 or 1)

Access: Can be written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $03E0_H$ + (m * 0004_H)

Initial value: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 21.75 RSCAN0TXQPCTRm register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should always be 0.
7 to 0	TXQPC[7:0]	Transmit Queue Pointer Control Writing FF_H to these bits moves the write pointer of the transmit queue to the next queue buffer. Set Value: FF_H

TXQPC[7:0] Bits

Writing FF_H to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCAN0TMIDp, RSCAN0TMPTRp, RSCAN0TMDF0p, and RSCAN0TMDF1p registers (p = 15 and 31) before writing FF_H to the TXQPC[7:0] bits.

Write FF_H only when the TXQE bit in the RSCAN0TXQCCm register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCAN0TXQSTSm register is set to 0 (not full).

21.3.57 RSCAN0THLCCm — Transmit History Configuration and Control Register (m = 0 or 1)

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0400_H + (m * 0004_H)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 21.76 RSCAN0THLCCm register contents

Bit Position	Bit Name	Function
31 to 11	Reserved	These bits are always read as 0. The write value should always be 0.
10	THLDTE	Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue
9	THLIM	Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored
8	THLIE	Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled.
7 to 1	Reserved	These bits are always read as 0. The write value should always be 0.
0	THLE	Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used.

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit only when the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of transmit messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

21.3.58 RSCAN0THLSTSm — Transmit History Status Register (m = 0 or 1)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0420_H + (m * 0004_H)

Initial value: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	THLMC[4:0]					—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 21.77 RSCAN0THLSTSm register contents

Bit Position	Bit Name	Function
31 to 13	Reserved	These bits are always read as 0. The write value should always be 0.
12 to 8	THLMC[4:0]	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	Reserved	These bits are always read as 0. The write value should always be 0.
3	THLIF	Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.
2	THLELT	Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	Transmit history Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCAN0THLCCm register occurs.

This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag.

THLELT Flag

The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (transmit history buffer is not used).

21.3.59 RSCAN0THLACCm — Transmit History Access Register (m = 0 or 1)

Access: Can be read in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 1800_H + (m * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.78 RSCAN0THLACCm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0.
15 to 8	TID[7:0]	Label Data The label information of stored data can be read.
7	Reserved	This bit is always read as 0.
6 to 3	BN[3:0]	Buffer Number Data The buffer number of transmit source (transmit buffer, transmit/receive FIFO or transmit queue) can be read.
2 to 0	BT[2:0]	Buffer Type Data b2 b1 b0 0 0 1: Transmit buffer 0 1 0: Transmit FIFO buffer 1 0 0: Transmit queue

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the transmit history data stored in the transmit history buffer.

21.3.60 RSCAN0THLPCTRm — Transmit History Pointer Control Register (m = 0 or 1)

Access: Can be written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0440_H + (m * 0004_H)

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 21.79 RSCAN0THLPCTRm register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should always be 0.
7 to 0	THLPC[7:0]	Transmit History List Pointer Control Writing FF_H to these bits moves the read pointer to the next unread data in the transmit history buffer. Set Value: FF_H

THLPC[7:0] Bits

When the THLPC[7:0] bits are set to FF_H, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCAN0THLSTSm register is decremented. Write FF_H to the THLPC[7:0] bits after reading from the RSCAN0THLACCm register.

Write FF_H only when the THLE bit in the RSCAN0THLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCAN0THLSTSm register is 0.

21.3.61 RSCAN0GTSTCFG — Global Test Configuration Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + 0468_H

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 21.80 RSCAN0GTSTCFG register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	These bits are always read as 0. The write value should always be 0.
1	C1ICBCE	CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.
0	C0ICBCE	CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled.

Modify the RSCAN0GTSTCFG register only in global test mode.

C1ICBCE Bit

Setting this bit to 1 enables the channel 1 inter-channel communication test.

C0ICBCE Bit

Setting this bit to 1 enables the channel 0 inter-channel communication test.

21.3.62 RSCAN0GTSTCTR — Global Test Control Register

Access: Can be read/written in 8-, 16-, and 32-bit units

Address: <RSCAN0_base> + $046C_H$

Initial value: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1

Note 1. Writing to these bits is effective only when the RS-CAN module is in global test mode.

Table 21.82 RSCAN0GLOCKK register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, an undefined value is returned. The write value should be 0.
15 to 0	LOCK[15:0]	Lock Key These bits are key bits to release protection of test mode.

The RSCAN0GLOCKK register releases protection of special test bits and is write-only.

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCAN0GTSTCTR register.

After the protection has been released, writing to the I/O register area (<RSCAN0_base> + 0000_H to <RSCAN0_base> + $04FF_H$) of the CAN (except the RAM) enables the protection again.

Reading from the I/O register area of the CAN or reading from/wring to other areas does not enable the protection.

21.4 Interrupt Sources

The RS-CAN module has 8 interrupts that are grouped into global interrupts and channel interrupts.

Global interrupts [2 sources: common among channels]:

- Receive FIFO interrupt [1 source: common among channels]
- Global error interrupt [1 source: common among channels]

Channel interrupts [6 sources: 3 sources × number of channels]:

- CANm transmit interrupt [1 source for each channel]
  - CANm transmit complete interrupt
  - CANm transmit abort interrupt
  - CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode)
  - CANm transmit history interrupt
  - CANm transmit queue Interrupt
- CANm transmit/receive FIFO receive complete interrupt (in transmit mode, gateway mode) [1 source for each channel]
- CANm error interrupt [1 source for each channel]

  (m = 0 or 1)

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is set to 1 (enabling interrupts), an interrupt request is output from the RS-CAN module. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the current interrupt request. The current interrupt request is still output until the interrupt request flag is cleared.

Table 21.83 lists the CAN interrupt sources. Figure 21.2 shows the CAN global interrupt block diagram. Figure 21.3 shows the CAN channel interrupt block diagram.

Table 21.83 List of CAN Interrupt Sources

Interrupt Source			Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Global interrupts	Receive FIFO	Receive FIFO 0	RFIF in the RSCAN0RFSTS0 register	RFIE in the RSCAN0RFCC0 register
		Receive FIFO 1	RFIF in the RSCAN0RFSTS1 register	RFIE in the RSCAN0RFCC1 register
		Receive FIFO 2	RFIF in the RSCAN0RFSTS2 register	RFIE in the RSCAN0RFCC2 register
		Receive FIFO 3	RFIF in the RSCAN0RFSTS3 register	RFIE in the RSCAN0RFCC3 register
		Receive FIFO 4	RFIF in the RSCAN0RFSTS4 register	RFIE in the RSCAN0RFCC4 register
		Receive FIFO 5	RFIF in the RSCAN0RFSTS5 register	RFIE in the RSCAN0RFCC5 register
		Receive FIFO 6	RFIF in the RSCAN0RFSTS6 register	RFIE in the RSCAN0RFCC6 register
		Receive FIFO 7	RFIF in the RSCAN0RFSTS7 register	RFIE in the RSCAN0RFCC7 register
	Global error		• DEF in the RSCAN0GERFL register • MES in the RSCAN0GERFL register • THLES in the RSCAN0GERFL register	• DEIE in the RSCAN0GCTR register • MEIE in the RSCAN0GCTR register • THLEIE in the RSCAN0GCTR register
Channel interrupts (m = 0 or 1)	CANm transmit	CANm transmit complete	TMTRF[1:0] in the RSCAN0TMSTSp register	TMIE in the RSCAN0TMIECy register
		CANm transmit abort	TMTRF[1:0] in the RSCAN0TMSTSp register	TAIE in the RSCAN0CmCTR register
		CANm transmit/receive FIFO transmit	CFTXIF in the RSCAN0CFSTSk register	CFTXIE in the RSCAN0CFCCk register
		CANm transmit queue	TXQIF in the RSCAN0TXQSTSm register	TXQIE in the RSCAN0TXQCCm register
		CANm transmit history	THLIF in the RSCAN0THLSTSm register	THLIE in the RSCAN0THLCCm register
	CANm transmit/receive FIFO receive		CFRXIF in the RSCAN0CFSTSk register	CFRXIE in the RSCAN0CFCCk register
	CANm error		• BEF in the RSCAN0CmERFL register • ALF in the RSCAN0CmERFL register • BLF in the RSCAN0CmERFL register • OVLF in the RSCAN0CmERFL register • BORF in the RSCAN0CmERFL register • BOEF in the RSCAN0CmERFL register • EPF in the RSCAN0CmERFL register • EWF in the RSCAN0CmERFL register	• BEIE in the RSCAN0CmCTR register • ALIE in the RSCAN0CmCTR register • BLIE in the RSCAN0CmCTR register • OLIE in the RSCAN0CmCTR register • BORIE in the RSCAN0CmCTR register • BOEIE in the RSCAN0CmCTR register • EPIE in the RSCAN0CmCTR register • EWIE in the RSCAN0CmCTR register

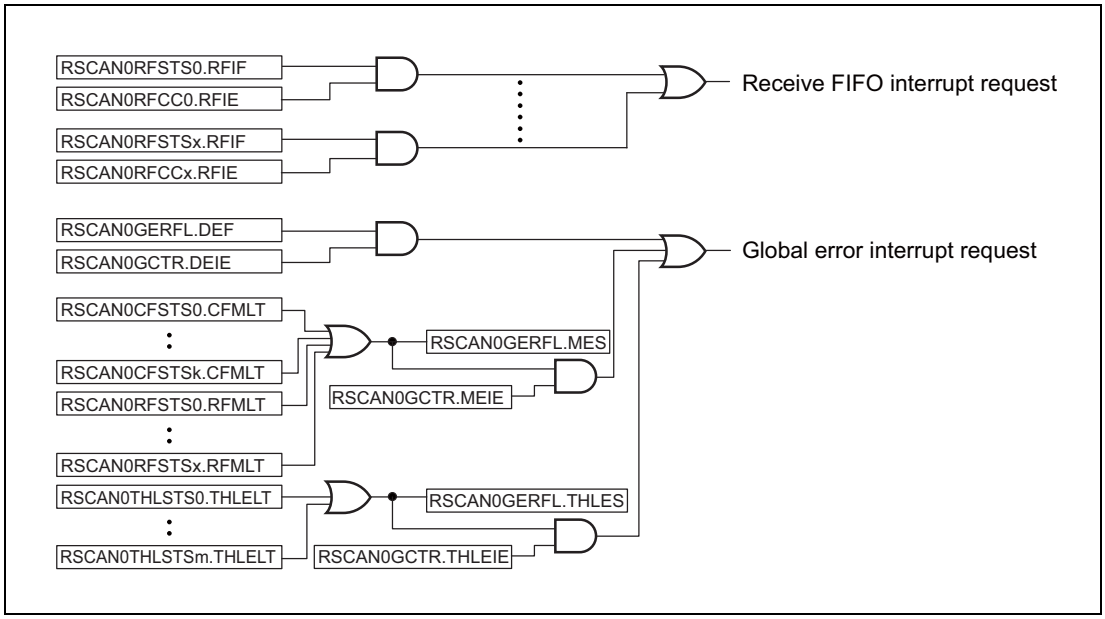

Figure 21.2 CAN Global Interrupt Block Diagram

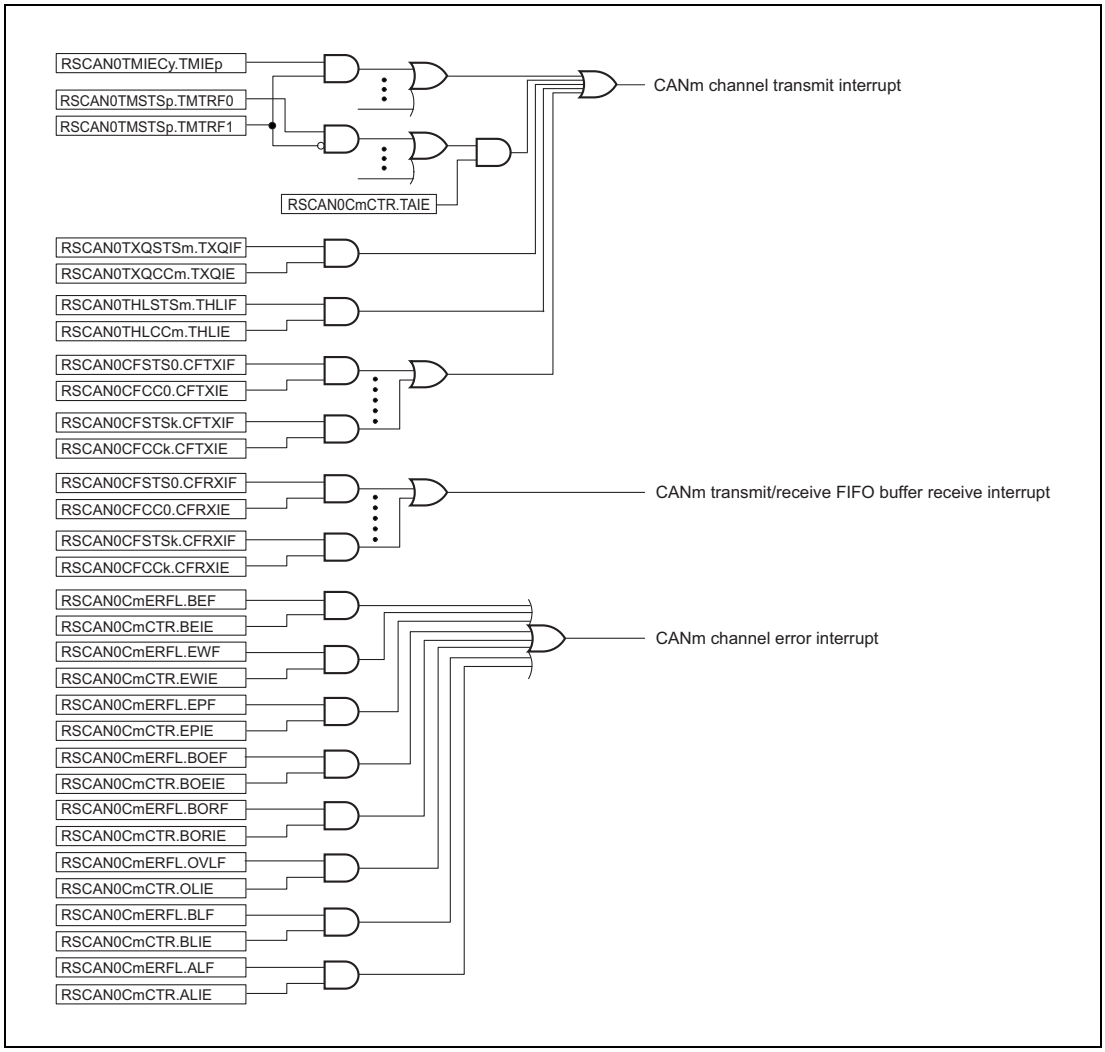

Figure 21.3 CAN Channel Interrupt Block Diagram

21.5 RSCAN Modes

The RS-CAN module has four global modes to control the entire RS-CAN module status and four channel modes to control individual channel status. Details of global modes are described in Section 21.5.1, Global Modes, and details of channel modes are described in Section 21.5.2, Channel Modes.

- Global stop mode: Stops the clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channels.
- Channel halt mode: Stops CAN communication and allows channel testing.
- Channel communication mode: Performs CAN communication.

21.5.1 Global Modes

Figure 21.4 shows the transitions of global modes.

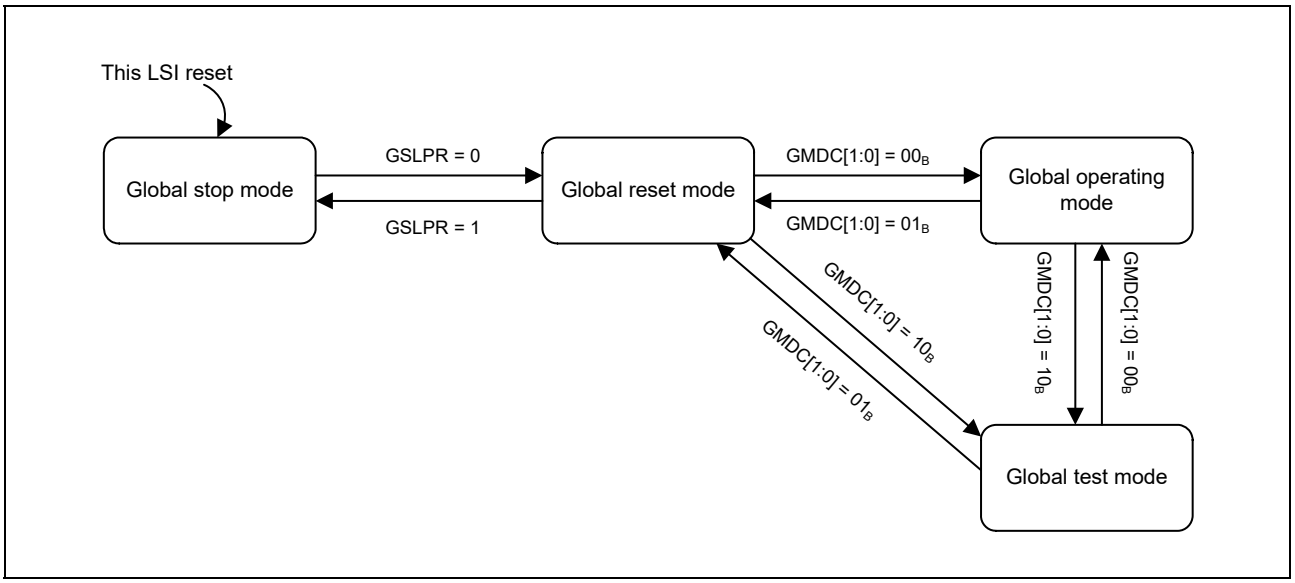

Figure 21.4 Transitions of Global Modes

In some cases, global mode transitions also force channel mode transitions. Table 21.84 shows the channel mode transitions depending on the global mode setting dictated by the GMDC[1:0] bits and the GSLPR bit.

Table 21.84 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

Channel Mode before Setting	Channel Mode after Setting			
	GMDC[1:0] = 00_B GSLPR = 0 (Global Operation)	GMDC[1:0] = 10_B GSLPR = 0 (Global Test)	GMDC[1:0] = 01_B GSLPR = 0 (Global Reset)	GMDC[1:0] = 01_B GSLPR = 1 (Global Stop)
Channel communication	Channel communication	Channel halt	Channel reset	Transition prohibited
Channel halt	Channel halt	Channel halt	Channel reset	Transition prohibited
Channel reset	Channel reset	Channel reset	Channel reset	Channel stop
Channel stop	Channel stop	Channel stop	Channel stop	Channel stop

Note: GMDC[1:0], GSLPR: Bits in the RSCAN0GCTR register

Table 21.85 shows the global mode transition time.

Table 21.85 Global Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Global stop	Global reset	Three pclk cycles
Global reset	Global stop	Three pclk cycles
Global reset	Global test	Ten pclk cycles
Global reset	Global operating	Ten pclk cycles
Global test	Global reset	Three pclk cycles
Global test	Global operating	Three pclk cycles
Global operating	Global reset	Three pclk cycles
Global operating	Global test	Two CAN frames*1

Note 1. CAN frame time of the lowest communication speed of the channels in use

21.5.1.1 Global Stop Mode

In global stop mode, clocks of the CAN do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. Only the clock used by the CPU for writing to the GSLPR bit runs in this mode.

After this LSI is reset, the CAN module transitions to global stop mode. Setting the GSLPR bit in the RSCAN0GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCAN0CmCTR register to 1 (channel stop mode). If all channels are forced to transition to channel stop mode, the CAN module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode or global test mode.

21.5.1.2 Global Reset Mode

In global reset mode, RS-CAN module settings are performed. When the RS-CAN module transitions to global reset mode, some registers are initialized. Table 21.88 and Table 21.89 list the registers to be initialized.

Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 01_B sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR registers (m = 0 or 1) to 01_B (channel reset mode). If all channels are forced to transition to channel reset mode, the CAN module transitions to global reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to 01_B).

21.5.1.3 Global Test Mode

In global test mode, settings for test-related registers are performed. When the CAN module transitions to global test mode, all CAN communications are disabled.

Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 10_B sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR register to 10_B (channel halt mode). If all channels are forced to transition to channel halt mode, the CAN module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

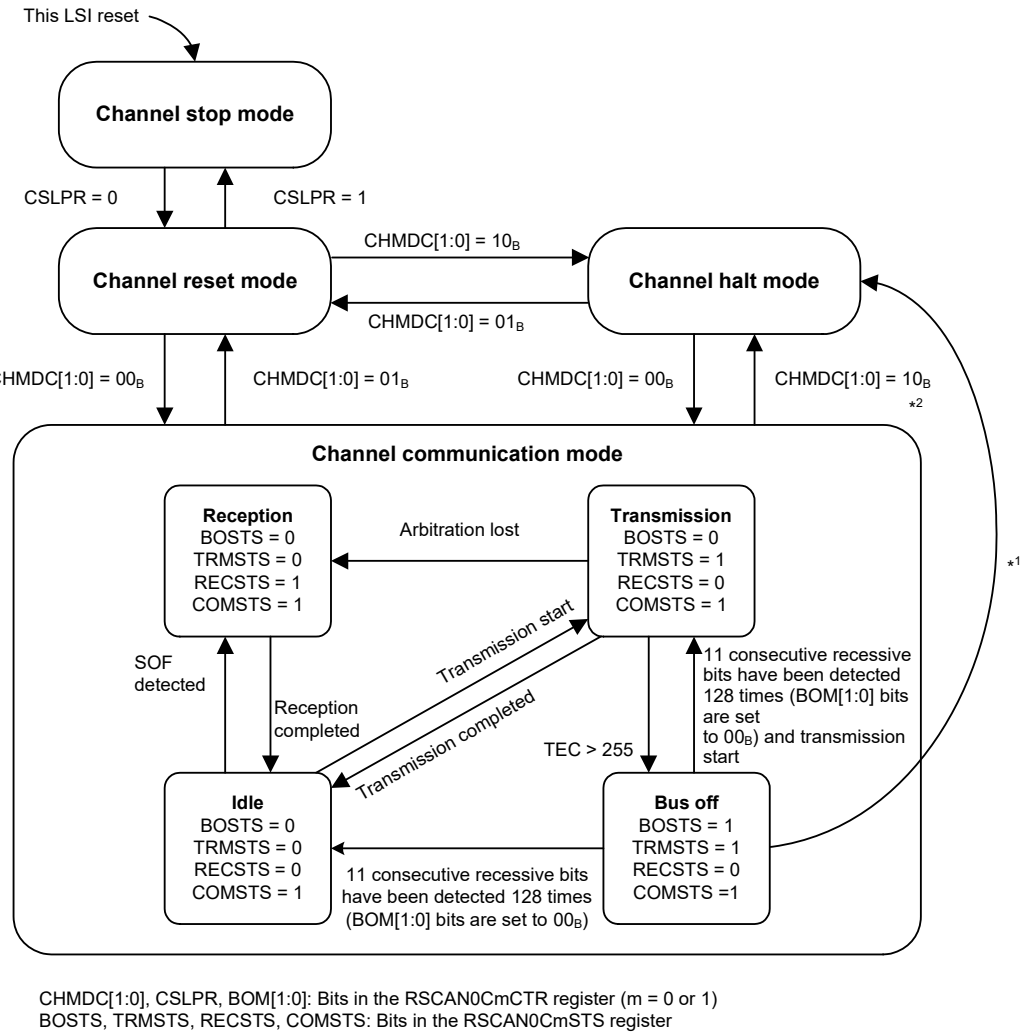
21.5.1.4 Global Operating Mode

The RS-CAN module operates in global operating mode.

When the GMDC[1:0] bits in the RSCAN0GCTR register are set to 00_B, the RS-CAN module transitions to global operating mode.

21.5.2 Channel Modes

Figure 21.5 shows a channel mode state transition chart. Table 21.86 shows the channel mode transition time.



CHMDC[1:0], CSLPR, BOM[1:0]: Bits in the RSCAN0CmCTR register (m = 0 or 1)
BOSTS, TRMSTS, RECSTS, COMSTS: Bits in the RSCAN0CmSTS register

Note 1. Timing of transition from bus off state to channel halt mode
- When BOM[1:0] = 01_B: Transition to channel halt mode when TEC exceeds 255
- When BOM[1:0] = 10_B: Transition to channel halt mode when 11 consecutive recessive bits have been detected 128 times
- When BOM[1:0] = 11_B: Transition to channel halt mode when the CHMDC[1:0] bits are set to 10_B

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode.

Figure 21.5 Channel Mode State Transition Chart

Table 21.86 Channel Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel stop	Channel reset	Three pclk cycles
Channel reset	Channel stop	Three pclk cycles
Channel reset	Channel halt	Three CANm bit times
Channel reset	Channel communication	Two CANm bit times
Channel halt	Channel reset	Three pclk cycles
Channel halt	Channel communication	Three CANm bit times
Channel communication	Channel reset	Three pclk cycles
Channel communication	Channel halt	Two CANm frames

21.5.2.1 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.

Each channel enters channel stop mode after this LSI is reset. Channels also transition to channel stop mode when the CSLPR bit in the RSCAN0CmCTR register (m = 0 or 1) is set to 1 (channel stop mode) in channel reset mode. The CSLPR bit should not be modified in channel communication mode and channel halt mode.

21.5.2.2 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. Table 21.88 lists the registers to be initialized.

When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01_B (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. Table 21.87 shows the operation when the CHMDC[1:0] bits are set to 01_B (channel reset mode) during CAN communication.

21.5.2.3 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.

Table 21.87 shows operation when the CHMDC[1:0] bits are set to 10_B (channel halt mode) during CAN communication.

Table 21.87 Operation a Channel Transitions to Channel Reset Mode/Channel Halt Mode

Mode	During Reception	During Transmission	Bus Off State
Channel reset (CHMDC[1:0] = 01_B)	Transitions to channel reset mode before reception is completed.<asterisk>*<Super_A>1	Transitions to channel reset mode before transmission is completed.<asterisk>*<Super_A>1	Transitions to channel reset mode before bus off recovery.
Channel halt<asterisk>*<Super_A>3 (CHMDC[1:0] = 10_B)	Transitions to channel halt mode after reception is completed.<asterisk>*<Super_A>2	Transitions to channel halt mode after transmission is completed.	[When BOM[1:0] = 00_B] Transitions to channel halt mode (CHMDC[1:0] = 10_B) only after bus off recovery. [When BOM[1:0] = 01_B] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = 10_B] Transitions to channel halt mode automatically after bus off recovery. [When BOM[1:0] = 11_B] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to 10_B before bus off recovery.

Note 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to 10_B and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to 01_B.

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCAN0CmERFL register that becomes 1 when dominant lock is detected.

Note 3. When the transition from channel reset mode to channel wait mode is to be made, set the RSCAN0CmCFG register in channel reset mode and then shift to channel wait mode.

21.5.2.4 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel has the following communication states during CAN communication.

- Idle : Neither reception nor transmission is in progress.
- Reception : Receiving a message sent from another node.
- Transmission : Transmitting a message.
- Bus off : Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 00_B, the channel transitions to channel communication mode. After that, once 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCAN0CmSTS register (m = 0 or 1) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

21.5.2.5 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/ decrement rules of the CAN specifications.

The conditions for returning from the bus off state are determined by the BOM[1:0] bits in the RSCAN0CmCTR register.

- When BOM[1:0] = 00_B:
  Bus off recovery is compliant with the CAN specifications. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are initialized to 00_H and the BORF flag in the RSCAN0CmERFL register is set to 1 (bus off recovery is detected). When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to B'10 (channel halt mode) in the bus off state, the channel transitions to channel halt mode after bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = 01_B:
  When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to 10_B and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1.
- When BOM[1:0] = 10_B:
  When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to 10_B. After bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H and the BORF flag is set to 1.
- When BOM[1:0] = 11_B:
  When the CHMDC[1:0] bits are set to 10_B in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1.
  However, the BORF flag becomes 1 if a CAN module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to 10_B.

If the RS-CAN module causes the channel to transition to channel halt mode simultaneously with a program write to the CHMDC[1:0] bits, the program write takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to 01_B or 10_B is made only when the CHMDC[1:0] bits are 00_B (channel communication mode). Furthermore, setting the RTBO bit in the RSCAN0CmCTR register to 1 allows a forced return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the CAN module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to 00_H. Write 1 to the RTBO bit only when the BOM[1:0] value is 00_B.

Table 21.88 Registers Initialized in Global Reset Mode or Channel Reset Mode

Register	Bit / Flag
RSCAN0CmCTR register	CTMS[1:0], CTME, CHMDC[1:0]
RSCAN0CmSTS register	CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, REC[7:0], TEC[7:0]
RSCAN0CmERFL register	CRCREG[14:0], ADERR, B0ERR, B1ERR, CERR, AERR, FERR, SERR, ALF, BLF, OVLF, BORF, BOEF, EPF, EWF, BEF
RSCAN0CFCCk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFE
RSCAN0CFSTSk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFMC[7:0], CFFLL, CFEMP, CFMLT, CFRXIF, CFTXIF
RSCAN0CFTISTS register	CFkTXIF
RSCAN0TMCp register	TMOM, TMTAR, TMTR
RSCAN0TMSTSp register	TMTARM, TMTRM, TMTRF[1:0], TMTSTS
RSCAN0TMTRSTSy register	TMTRSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTARSTSy register	TMTARSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTCSTSy register	TMTCSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTASTSy register	TMTASTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TXQCCm register	TXQE
RSCAN0TXQSTSm register	TXQIF, TXQFLL, TXQEMP
RSCAN0THLCCm register	THLE
RSCAN0THLSTSm register	THLMC[4:0], THLIF, THLELT, THLFLL, THLEMP
RSCAN0GTINTSTS0 register	TSIFm, TAIFm, TQIFm, CFTIFm, THIFm (m = 0 or 1)

Table 21.89 Registers Initialized Only in Global Reset Mode

Register	Bit / Flag
RSCAN0GSTS register	GHLTSTS
RSCAN0GERFL register	THLES, MES, DEF
RSCAN0GTSC register	TS[15:0]
RSCAN0RMNDy register	RMNSq
RSCAN0RFCCx register	RFE
RSCAN0RFSTSx register	RFMC[7:0], RFIF, RFMLT, RFFLL, RFEMP
RSCAN0CFCCk register	When transmit/receive FIFO buffer is in receive mode: CFE
RSCAN0CFSTSk register	When transmit/receive FIFO buffer is in receive mode: CFMC[7:0], CFFLL, CFEMP, CFTXIF, CFRXIF, CFMLT
RSCAN0FESTS register	CFkEMP, RFxEMP
RSCAN0FFSTS register	CFkFLL, RFxFLL
RSCAN0FMSTS register	CFkMLT, RFxMLT
RSCAN0RFISTS register	RFxIF
RSCAN0CFRISTS register	CFkRXIF
RSCAN0GTSTCFG register	C0ICBCE, C1ICBCE
RSCAN0GTSTCTR register	ICBCTME

21.6 Reception Function

There are two reception types.

- Reception by receive buffers:
  Zero to 31 receive buffers can be shared by all channels. Since messages stored in receive buffers are overwritten at each reception, the latest receive data can always be read.
- Reception by receive FIFO buffers and transmit/receive FIFO buffers (receive mode):
  Eight receive FIFO buffers can be shared by all channels and three dedicated transmit/receive FIFO buffers are provided for each channel. Messages of up to the number of buffer stages specified with the RFDC[2:0] and CFDC[2:0] bits can be stored in FIFO buffers and can be read sequentially from the oldest.

21.6.1 Data Processing Using the Receive Rule Table

Data processing using the receive rule table allows dispatching of selected messages to the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 receive rules can be registered per channel and up to (64 × number of channels) total receive rules can be registered in the entire module. (Up to 128 receive rules can be registered in this module that has two channels.) Set receive rules for each channel. Receive rules cannot be shared with other channels. If receive rules are not set, no messages can be received. Figure 21.6 illustrates how receive rules are registered.

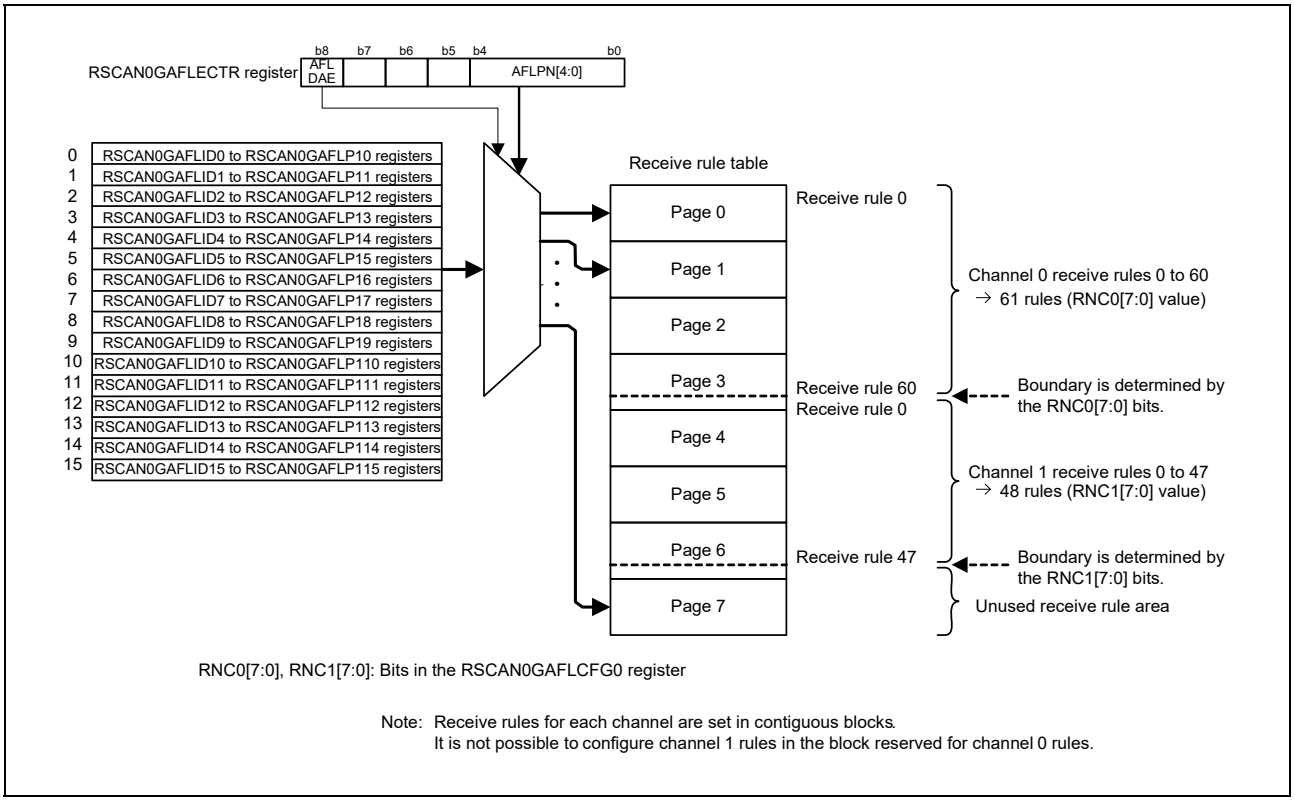


Figure 21.6 Entry of Receive Rules (for Setting Channel 0 and 1)

Each receive rule consists of 16 bytes in the RSCAN0GAFLIDj, RSCAN0GAFLMj, RSCAN0GAFLP0j, and RSCAN0GAFLP1j registers (j = 0 to 15). The RSCAN0GAFLIDj register (j = 0 to 15) is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function, the RSCAN0GAFLMj register is used to set mask, the RSCAN0GAFLP0j register is used to set label information to be added, DLC value, and storage receive buffer, and the RSCAN0GAFLP1j register is used to set storage FIFO buffer. Up to 16 receive rules can be set per page.

21.6.1.1 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the receive rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. The ID data, IDE bit, and RTR bit in the received message which correspond to the bits set to 0 (bits are not compared) in the RSCAN0GAFLMj register are not compared and are regarded as matched.

Check begins with the receive rule of the minimum number for the corresponding channel. When all the bits to be compared in a received message match the bits set in the receive rule or when all the receive rules are compared without any match, filter processing stops. If there is no matching receive rule, the received message is not stored in the receive buffer or FIFO buffer.

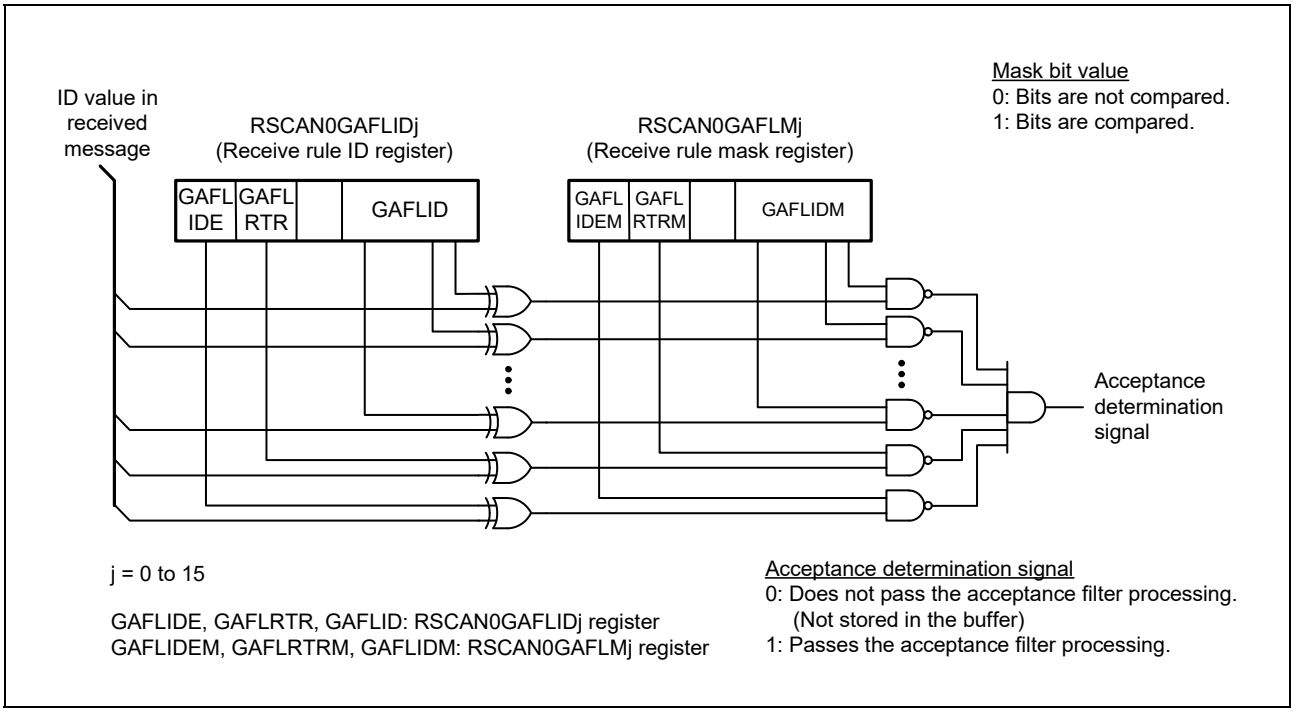

Figure 21.7 Acceptance Filter Function

21.6.1.2 DLC Filter Processing

When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the receive rule, the message passes through the DLC filter processing.

When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 0 (DLC replacement is disabled), the DLC value in the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.

When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 1 (DLC replacement is enabled), the DLC value in the receive rule is stored in the buffer instead of the DLC value in the received message. In this case, a value of 00_H is stored in each data byte beyond the number of bytes which is indicated by the DLC value in the receive rule.

When the DLC value in the received message is smaller than that in the receive rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the receive buffer or the FIFO buffer and the DEF flag in the RSCAN0GERFL register is set to 1 (a DLC error is present).

21.6.1.3 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in receive buffers, receive FIFO buffers, or transmit/receive FIFO buffers (set to receive mode or gateway mode). Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCAN0GAFLP0j register (j = 0 to 15) and by the RSCAN0GAFLP1j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to eight buffers.

21.6.1.4 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits in the RSCAN0GAFLP0j register.

21.6.1.5 Mirror Function Processing

The mirror function allows the CAN node to receive its own transmitted messages. The mirror function is made available by setting the MME bit in the RSCAN0GCFG register to 1 (mirror function is enabled).

When the mirror function is in use, receive rules for which the GAFLLB bit in the RSCAN0GAFLIDj register is set to 0 are used for data processing when receiving messages transmitted from other CAN nodes. When the CAN node is receiving its own transmitted messages, receive rules for which the GAFLLB bit is set to 1 are used for data processing.

21.6.1.6 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording message receive time. The timestamp counter value is fetched at the start-of-frame (SOF) timing of a message and is then stored in a receive buffer or a FIFO buffer together with the message ID and data. Ether pclk or the CANm bit time clock (m = 0 or 1) may be selected as a timestamp counter clock source using the TSBTCS[2:0] and TSSS bits in the RSCAN0GCFG register. The timestamp counter count source is obtained by dividing the selected clock source by the TSP[3:0] value in the RSCAN0GCFG register.

When the CANm bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When the pclk is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to 0000_H by setting the TSRST bit in the RSCAN0GCTR register to 1.

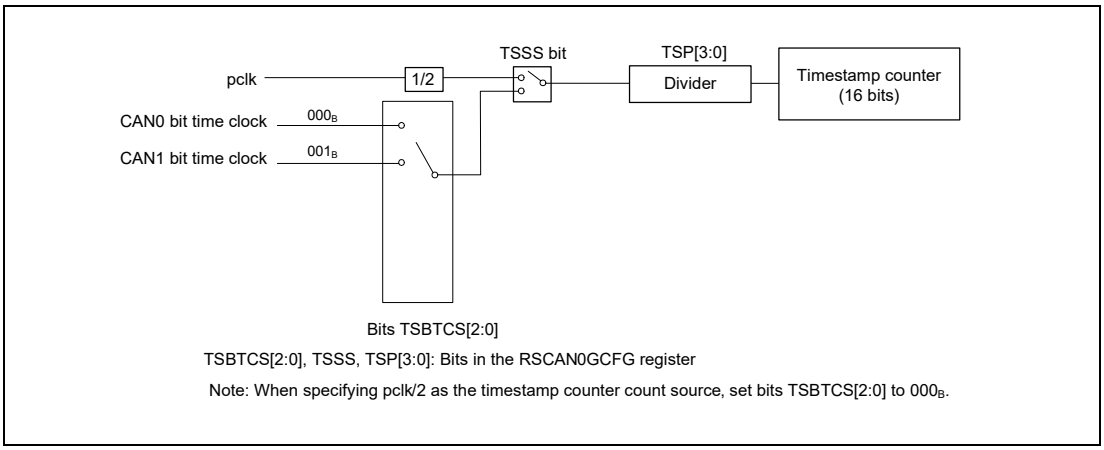

Figure 21.8 Timestamp Function Block Diagram

21.7 Transmission Functions

There are three types of transmission.

- Transmission using transmit buffers:
  Each channel has 16 buffers.
- Transmission using transmit/receive FIFO buffers (transmit mode):
  Each channel has three FIFO buffers. Up to 96 messages can be contained in a single FIFO buffer. Each FIFO buffer is used with a link to a transmit buffer. Only the message to be transmitted next in a FIFO buffer becomes the target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.
- Transmission using transmit queues:
  Up to 16 transmit buffers per channel can be allocated to the transmit queues. Transmit buffer ((16 × m) + 15) is used as an access window of a corresponding channel. Transmit buffers are allocated to transmit queues in descending order of buffer number. All messages in transmit queues, which are targets of priority determination, are transmitted in the order of ID number.

Figure 21.9 shows the allocation of transmit queues and transmit/receive FIFO buffer link.

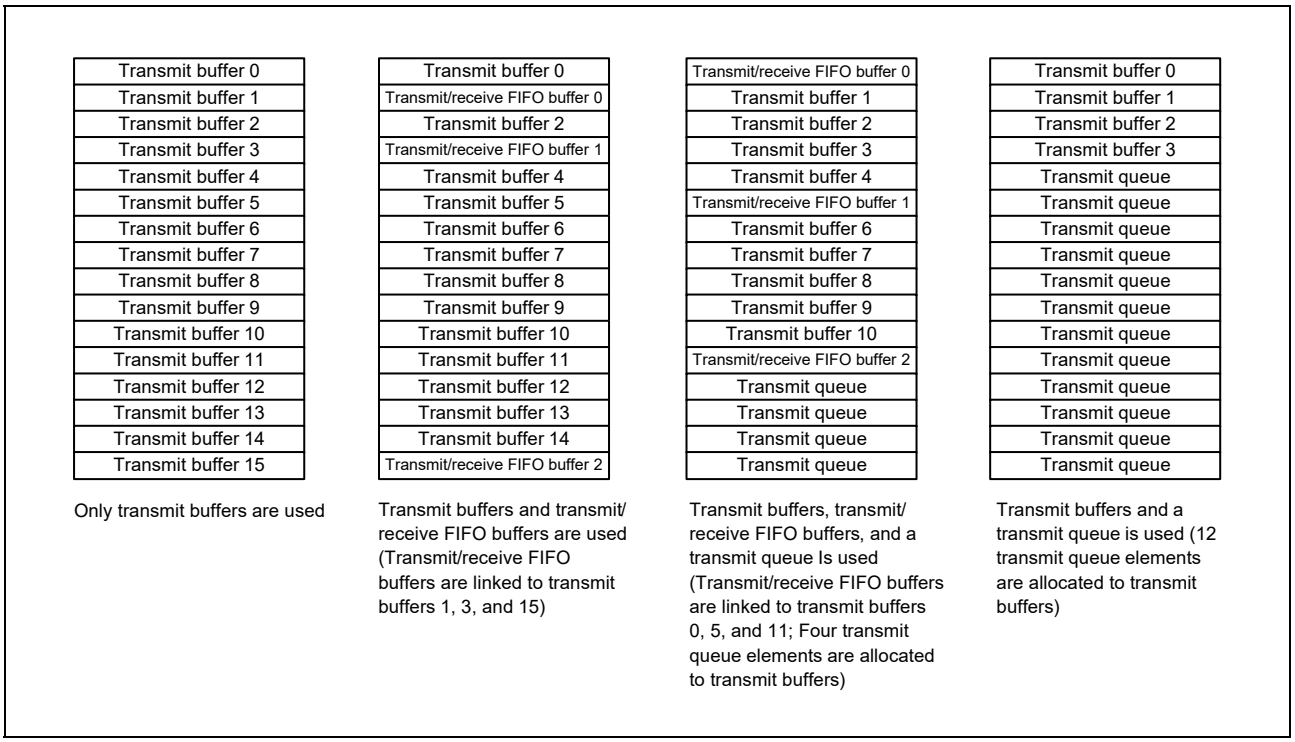

Figure 21.9 Allocation of Transmit Queues and Transmit/Receive FIFO Buffer Links

21.7.1 Transmit Priority Determination

If transmit requests are issued from multiple buffers or from the queue on the same channel, transmit priority is determined using one of the following methods.

The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmit buffer number priority (TPRI bit = 1)

All CAN channels use the setting of the TPRI bit in the RSCAN0GCFG register.

When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. ID priority conforms to the CAN bus arbitration specification defined in the CAN specifications. All IDs of pending transmit messages are targets of priority determination, regardless of whether they are stored in transmit buffers, transmit/receive FIFO buffers (set to transmit mode or gateway mode), or the transmit queue. If even a single transmit queue is used, select ID priority. When transmit/receive FIFO buffers are used, the oldest message in a FIFO buffer becomes the target of priority determination. When a message is being transmitted from a transmit/receive FIFO buffer, the next message in the FIFO buffer becomes the target of priority determination. When a transmit queue is used, all messages in the transmit queue are targets of priority determination. If the same ID is set for two or more buffers, the buffer with the smaller buffer number takes precedence.

When the TPRI bit is set to 1, the message in the transmit buffer with the minimum buffer number among all buffers with a transmit request is transmitted first. When transmit/receive FIFO buffers are linked to transmit buffers, transmit priority is determined according to linked transmit buffer numbers.

When messages are retransmitted due to an arbitration-lost or an error, transmit priority determination is made again regardless of the TPRI bit.

21.7.2 Transmission Using Transmit Buffers

Setting the transmit request bit (TMTR bit in the RSCAN0TMCp register) in a transmit buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.

The transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register (p = 0 to 31). When transmit completes successfully, the TMTRF[1:0] flag is set to 10_B (transmission has been completed (without transmit abort request)) or 11_B (transmission has been completed (with transmit abort request)).

21.7.2.1 Transmit Abort Function

With respect to transmit buffers for which the TMTRM bit in the RSCAN0TMSTSp register is set to 1 (a transmit request is present), when the TMTAR bit in the RSCAN0TMCp register is set to 1 (transmit abort is requested), the transmit request is canceled. When transmit abort is completed, the TMTRF[1:0] flag in the RSCAN0TMSTSp register is set to 01_B (transmit abort has been completed) and the transmit request is canceled (clearing the TMTRM bit to 0).

A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, when an arbitration-lost or an error occurs during transmission of a message for which the TMTAR bit is set to 1, retransmission is not performed.

21.7.2.2 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit in the RSCAN0TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration-lost or an error occurs, retransmission is not performed.

The one-shot transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register. When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to 10_B or 11_B. When an arbitration-lost or an error occurs, the TMTRF[1:0] flag is set to 01_B (transmit abort has been completed).

21.7.3 Transmission Using FIFO Buffers

Multiple messages can be stored in a single transmit/receive FIFO buffers, up to the number specified by the FIFO buffer depth, which is set by the CFDC[2:0] bits in the RSCAN0CFCCk register (k = 0 to 5). Messages are transmitted sequentially on a first-in, first-out basis.

Each transmit/receive FIFO buffer is linked to a transmit buffer selected by the CFTML[3:0] bits in the RSCAN0CFCCk register. When the CFE bit in the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO buffers are used), transmit/receive FIFO buffers become targets of transmit priority determination. Priority of only the next transmit message is determined in the FIFO buffer.

When the CFE bit is set to 0 (no transmit/receive FIFO buffer is used), the CFEMP flag is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately if the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost in the case that a message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

21.7.3.1 Interval Transmission Function

A message transmission interval time can be set to space the transmission of messages from the same FIFO buffer when using a transmit/receive FIFO buffer set to transmit mode or gateway mode.

Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit in the RSCAN0CFCCk register set to 1, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.

The interval time is set by the CFITT[7:0] bits in the RSCAN0CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to 00_H.

Select an interval timer count source using the CFITR and CFITSS bits in the RSCAN0CFCCk register. When the CFITR and CFITSS bits are set to 00_B, the count source is obtained by dividing pclk/2 by the value of the ITRCP[15:0] bits. When the CFITR and CFITSS bits are set to 10_B, the count source is obtained by dividing pclk/2 by (the value of the ITRCP[15:0] bits in the RSCAN0GCFG register × 10). When the CFITR and CFITSS bits are set to $x1_B$, the CANm bit time clock is used as a count source.

The interval time is calculated by the following equations where M is the value set to ITRCP[15:0] and N is the set CFITT[7:0] value.

- When CFITR and CFITSS = 00_B (fPBA is the frequency of pclk):

$$\frac{1}{f_{PBA}} \times 2 \times M \times N$$

- When CFITR and CFITSS = 10_B:

$$\frac{1}{f_{PBA}} \times 2 \times M \times 10 \times N$$

- When CFITR and CFITSS = $x1_B$ (fCANBIT is the frequency of CANm bit time clock):

$$\frac{1}{f_{CANBIT}} \times N$$

Figure 21.10 shows the interval timer block diagram.

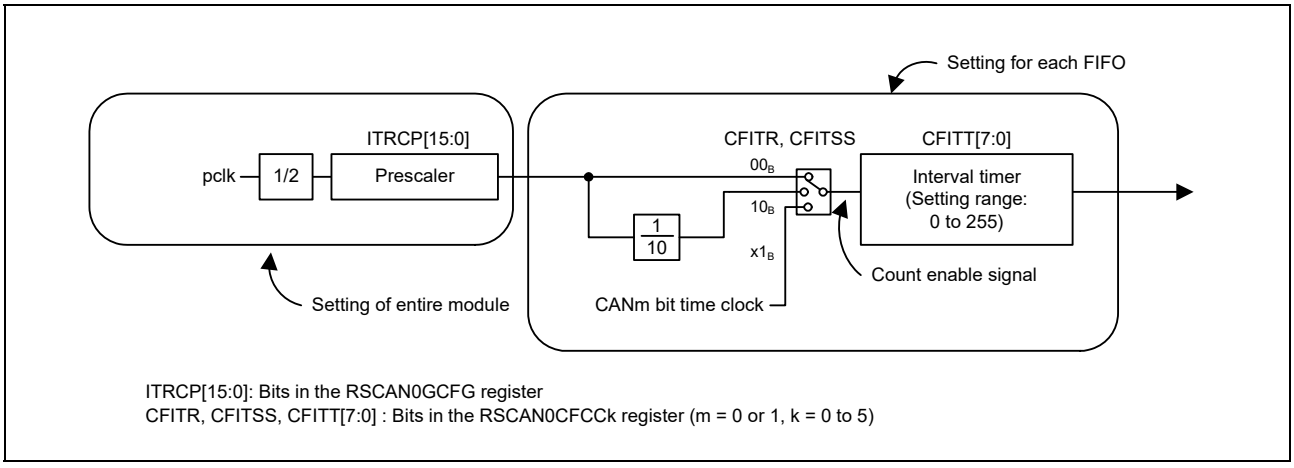

Figure 21.10 Interval Timer Block Diagram

Figure 21.11 shows the interval timer timing diagram.

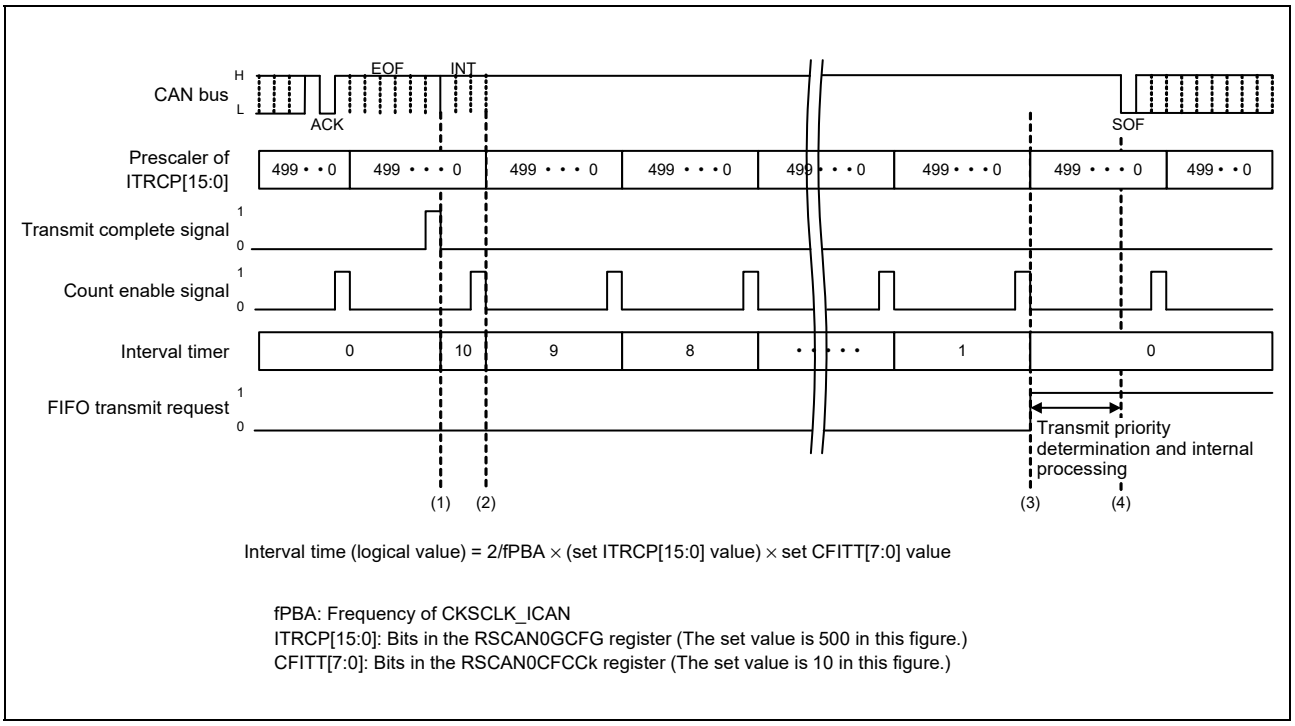

Figure 21.11 Interval Timer Timing Chart

(1) The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time contains an error of up to one count of the interval timer.

(2) The interval timer is decremented by the next count enable signal.

(3) When the interval timer has decreased to 0, the transmit/receive FIFO buffer issues a transmit request.

(4) The transmit/receive FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmit request. If multiple internal processes (such as receive filter processing, message routing, and transmit priority determination) take place in all channels, a delay of up to 504 cycles of pclk may be generated.

21.7.4 Transmission Using Transmit Queues

Three to sixteen buffers are allocated to a transmit queue for each channel, and transmit buffer ((16 × m) + 15) is used as an access window of a corresponding channel.

All messages in a transmit queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of storage sequence. If two messages having the same ID are stored in a transmit queue, these messages are not always transmitted in the order of their storage in the transmit queue.

Setting the TXQE bit in the RSCAN0TXQCCm register to 0 disables transmit queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCAN0TXQSTSm register is set to 1 (the transmit queue contains no messages (transmit queue empty)) at the timing below.

- The transmit queue becomes empty immediately when no message in it is being transmitted or will be transmitted next.
- The transmit queue becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when a message in it is being transmitted or will be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmit queues are lost and messages cannot be stored in transmit queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

21.7.5 Transmit History Function

Information about transmitted messages can be stored in the transmit history buffer. Each channel has a single transmit history buffer that can contain 16 sets of transmit history data.

A message transmit source buffer type can be selected by the THLDTE bit in the RSCAN0THLCCm register. The THLEN bit in the RSCAN0CFIDk register (k = 0 to 5) determines whether transmit history data is stored for each message.

The following information on a transmitted message will be stored in the transmission history buffer after the successful completion of transmission.

Storage of the transmission history data after the successful completion of transmission may take up to 144 cycles of pclk.

- Buffer type
  001_B: Transmit buffer
  010_B: Transmit/receive FIFO buffer
  100_B: Transmit queue
- Buffer number
  Number of source transmit buffer, transmit queue, or transmit/receive FIFO buffer.
  This number depends on buffer types. See Table 21.90.
- Label data
  Label information of the transmit message

Table 21.90 Transmit History Data Buffer Numbers

Buffer type / Buffer No.	001_B	010_B	100_B
0000_B	Transmit buffer 16 × m + 0	Buffer numbers of the transmit buffer linked to the transmit/ receive FIFO buffer by the CFTML[3:0] bits in the RSCAN0CFCCk register (k = 0 to 5)	Buffer numbers of the transmit buffer allocated to the transmit queue that performed transmission
0001_B	Transmit buffer 16 × m + 1		
0010_B	Transmit buffer 16 × m + 2		
0011_B	Transmit buffer 16 × m + 3		
0100_B	Transmit buffer 16 × m + 4		
0101_B	Transmit buffer 16 × m + 5		
0110_B	Transmit buffer 16 × m + 6		
0111_B	Transmit buffer 16 × m + 7		
1000_B	Transmit buffer 16 × m + 8		
1001_B	Transmit buffer 16 × m + 9		
1010_B	Transmit buffer 16 × m + 10		
1011_B	Transmit buffer 16 × m + 11		
1100_B	Transmit buffer 16 × m + 12		
1101_B	Transmit buffer 16 × m + 13		
1110_B	Transmit buffer 16 × m + 14		
1111_B	Transmit buffer 16 × m + 15		

Label data is used to identify each message. Unique label data can be added to each message transmitted from a transmit buffer, transmit queue, or transmit/receive FIFO buffer.

Transmit history data can be read from the RSCAN0THLACCm register. If an attempt is made to store new transmit history data while the buffer is full, the buffer overflows and the new data is discarded.

21.8 Gateway Function

When a transmit/receive FIFO buffer is set to gateway mode, receive massages can be transmitted from an arbitrary channel without CPU intervention.

When a transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCAN0CFCCk register are set to 10_B (gateway mode) is selected by the RSCAN0GAFLP1j register, messages that passed through the filter processing of the receive rule are stored in the specified transmit/receive FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmit/receive FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes the target of transmit priority determination.

Transmit/receive FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCAN0CFCCk register to 0 and the CFEMP flag becomes 1 according to the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the oldest message in it is not being transmitted and will not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when the message in it is being transmitted or will be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages can no longer be stored in transmit/receive FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

21.9 Test Function

The test function is classified into communication tests and global tests.

- Communication tests: Performed for each channel.
  - Standard test mode
  - Listen-only mode
  - Self-test mode 0 (external loopback mode)
  - Self-test mode 1 (internal loopback mode)
- Global tests: Performed for the entire module
  - Inter-channel communication test

21.9.1 Standard Test Mode

Standard test mode allows CRC test.

21.9.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted.

Listen-only mode is available for detecting the communication speed.

Do not make a transmit request from any buffer or queue in listen-only mode.

Figure 21.12 shows the connection when listen-only mode is selected.

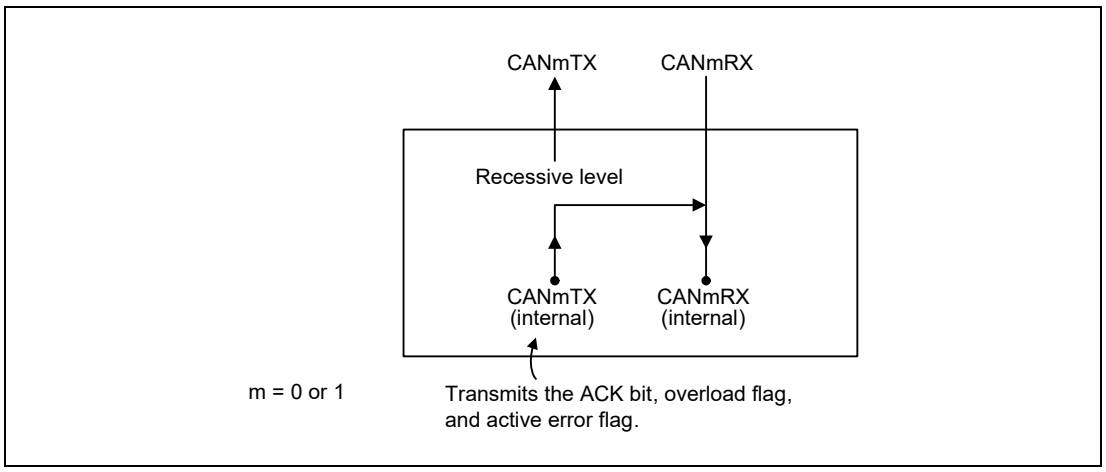

Figure 21.12 Connection when Listen-Only Mode is Selected

21.9.3 Self-Test Mode (Loopback Mode)

In self-test mode, transmitted messages are compared with the receive rule of the own channel and the messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the receive rule for which the GAFLLB bit in the RSCAN0GAFLIDj register (j = 0 to 15) is set to 0 (when a message transmitted from another CAN node is received).

If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

21.9.3.1 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.

In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

Figure 21.13 shows the connection when self-test mode 0 is selected.

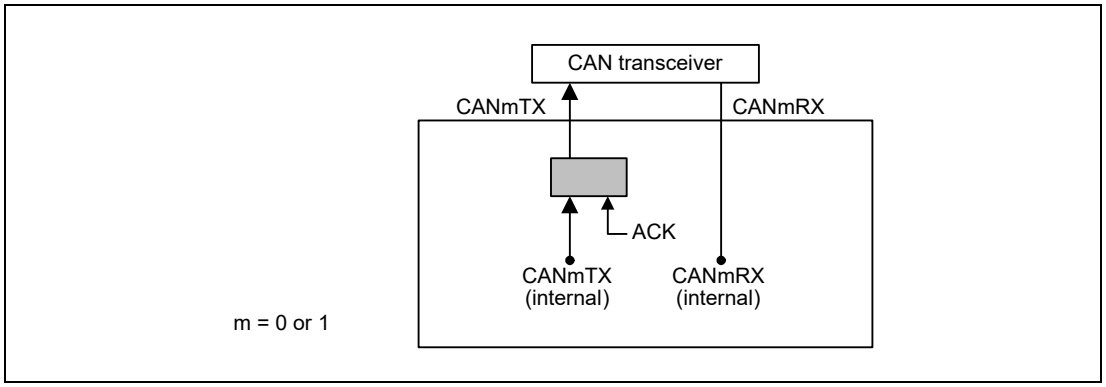

Figure 21.13 Connection when Self-Test Mode 0 is Selected

21.9.3.2 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

In self-test mode 1, internal feedback from the internal CANmTX pin (m = 0 or 1) to the internal CANmRX pin is performed. The external CANmRX pin input is isolated. The external CANmTX pin outputs only recessive bits.

Figure 21.14 shows the connection when self-test mode 1 is selected.

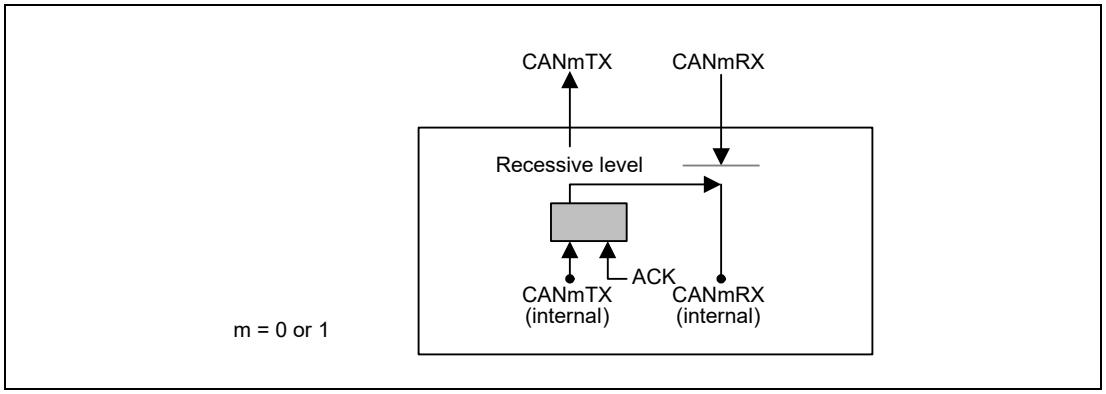

Figure 21.14 Connection when Self-Test Mode 1 is Selected

21.9.4 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally connecting CAN channels to each other. During this test, channels are isolated from the external CAN bus.

Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel.

Figure 21.15 shows the connection for inter-channel communication test.

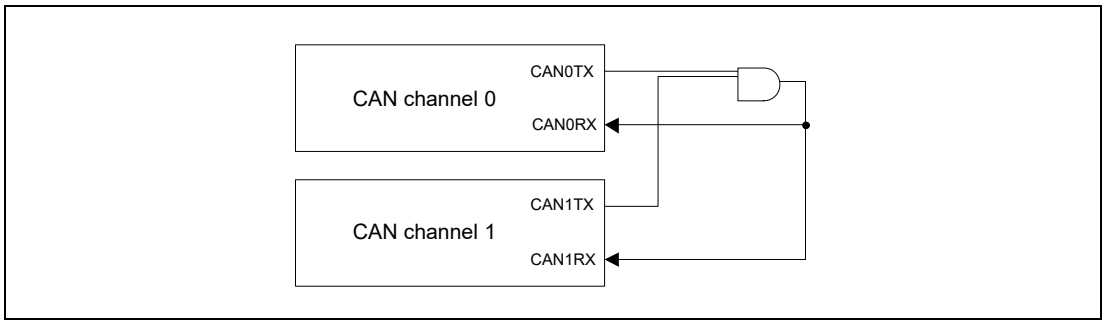

Figure 21.15 Connection for Inter-Channel Communication Test

21.10 RS-CAN Setting Procedure

21.10.1 Initial Settings

The RS-CAN module initializes the CAN RAM after this LSI is reset. The RAM initialization time is 6082 cycles of pclk. The GRAMINIT flag in the RSCAN0GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Make CAN settings after the GRAMINIT flag is cleared to 0. Figure 21.16 shows the CAN setting procedure after this LSI is reset.

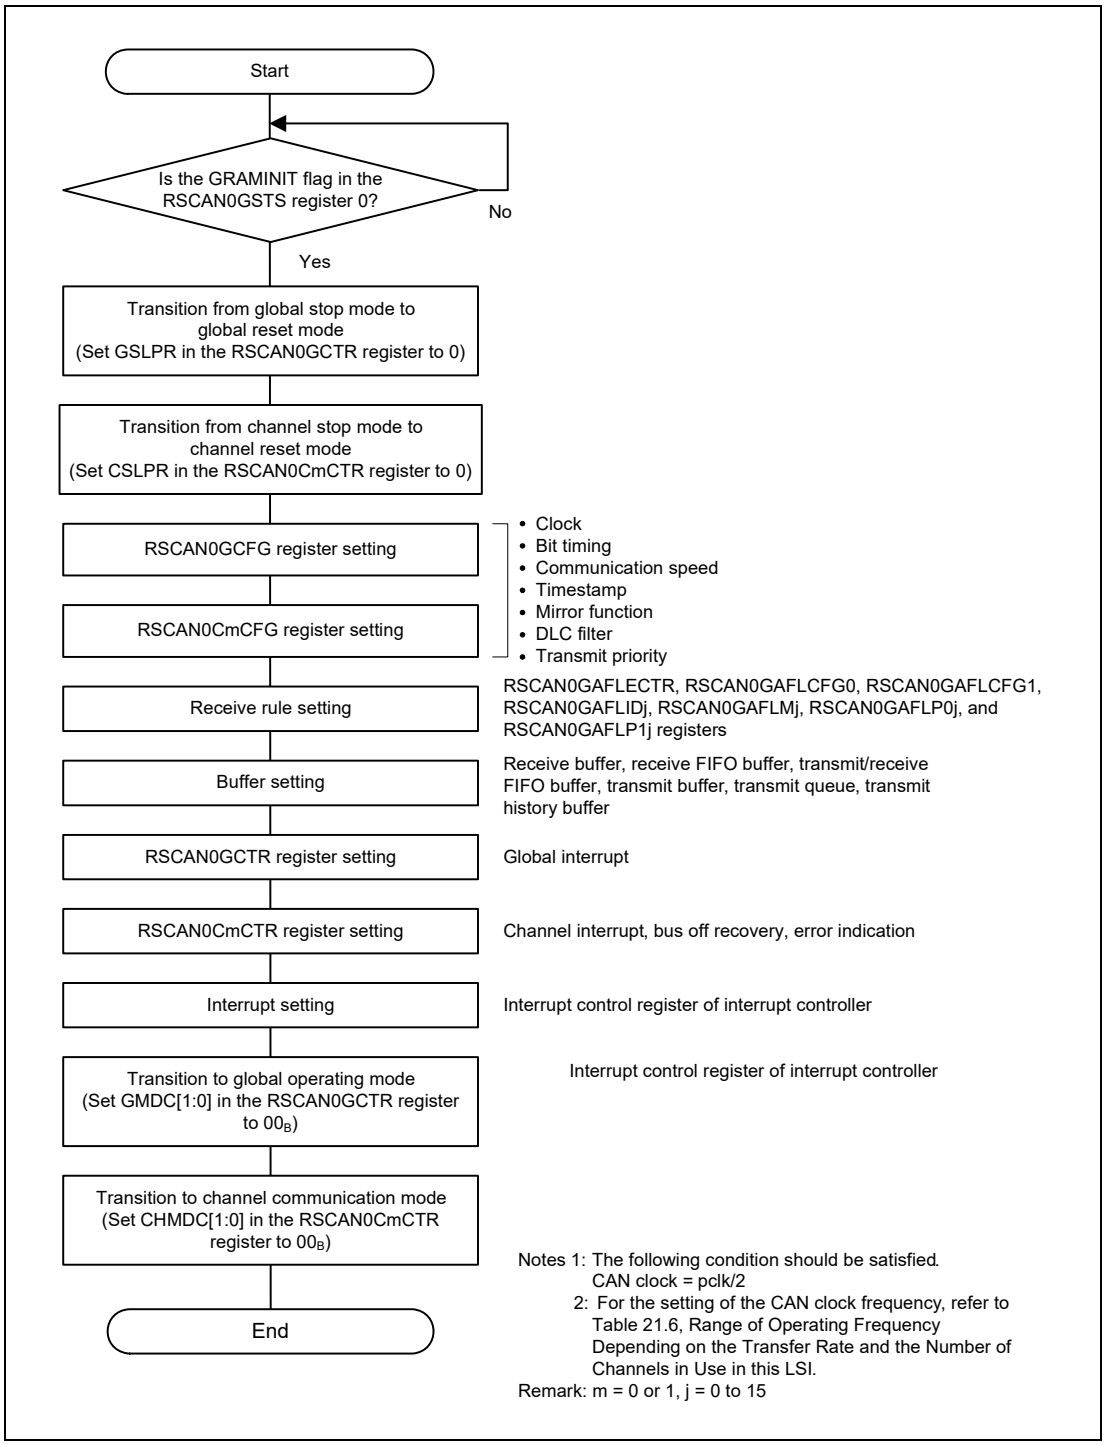

Figure 21.16 CAN Setting Procedure after the this LSI is Reset

21.10.1.1 Clock Setting

Set the CAN clock (fCAN) as a clock source of the RS-CAN module. Select the clk_xincan or clkc using the DCS bit in the RSCAN0GCFG register.

21.10.1.2 Bit Timing Setting

In the CAN protocol, one bit of a communication frame consists of three segments SS, TSEG1, and TSEG2. Two of the segments, TSEG1 and TSEG2, can be set by the RSCAN0CmCFG register for each channel. Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 Time Quantum (referred to as Tq hereinafter). 1 Tq is equal to one CANmTq clock cycle. The CANmTq clock is obtained by selecting the clock source with the DCS bit in the RSCAN0GCFG register and selecting the clock division ratio with the BRP[9:0] bits in the RSCAN0CmCFG register.

Figure 21.17 shows the bit timing chart. Table 21.91 shows an example of bit timing setting.

SS = 1 Tq fixed
Set TSEG1 to a range of 4 Tq to 16 Tq
Set TSEG2 to a range of 2 Tq to 8 Tq
Set SJW to a range of 1 Tq to 4 Tq
Set SS + TSEG1 + TSEG2 to a range of 8 Tq to 25 Tq
TSEG1 > TSEG2 ≥ SJW

- SS (synchronization segment):
  The SS is a segment that performs synchronization by monitoring the edge from recessive to dominant bits in the Interframe Space.
  Interframe Space consists of Intermission, Suspend Transmission, and Bus Idle. All nodes can start transmission during Bus Idle.
- TSEG1 (Time segment 1):
  TSEG1 is a segment that absorbs physical delay on the CAN network. The physical delay on the CAN network is twice the total of the delay on the CAN bus, the delay in the input comparator, and the delay in the output driver.
- TSEG2 (Time segment 2):
  TSEG2 is a segment that compensates phase error due to an error in frequency.
- SJW (Resynchronization jump width)
  The SJW is a length to extend or reduce the time segment to compensate for an error in phase due to phase error.

Figure 21.17 Bit Timing Chart

Table 21.91 Example of Bit Timing Setting

1 Bit	Set Value (Tq)				Sample Point (%) Note: See Figure 21.17.
	SS	TSEG1	TSEG2	SJW	
8Tq	1	4	3	1	62.50
	1	5	2	1	75.00
12Tq	1	8	3	1	75.00
	1	9	2	1	83.33
16Tq	1	10	5	1	68.75
	1	11	4	1	75.00
24Tq	1	14	9	1	62.50
	1	15	8	1	66.66

21.10.1.3 Communication Speed Setting

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value (BRP[9:0] bits in the RSCAN0CmCFG register), and Tq count per bit time.

Figure 21.18 shows the CAN clock control block diagram, and Table 21.92 shows an example of the communication speed setting.

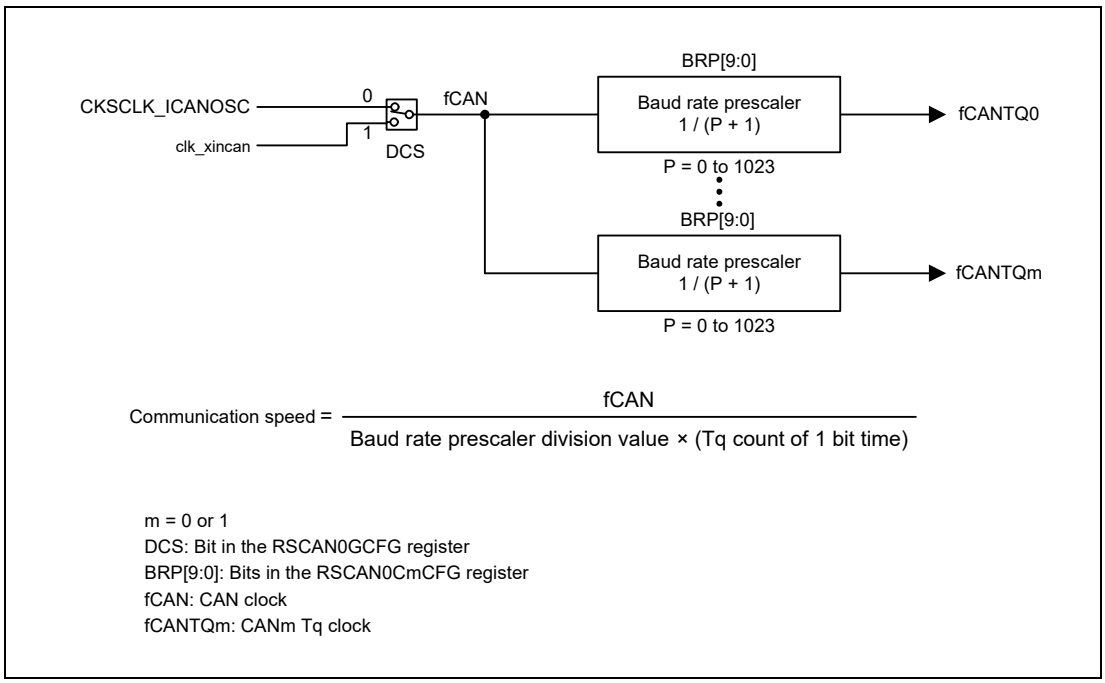

Figure 21.18 CAN Clock Control Block Diagram

Table 21.92 Example of Communication Speed Setting

fCAN / Communication speed	32MHz	24MHz	8MHz
1Mbps	8Tq (4) 16Tq (2)	8Tq (3) 12Tq (2) 24Tq (1)	8Tq (1)
500Kbps	8Tq (8) 16Tq (4)	8Tq (6) 12Tq (4) 24Tq (2)	8Tq (2) 16Tq (1)
125Kbps	8Tq (32) 16Tq (16)	8Tq (24) 12Tq (16) 24Tq (8)	8Tq (8) 16Tq (4)

Note: Values in ( ) are baud rate prescaler division values.

21.10.1.4 Receive Rule Setting

Receive rules can be set using receive rule-related registers.

Up to 16 receive rules can be registered per page. Specify pages 0 to 7 by the AFLPN[4:0] bits in the RSCAN0GAFLECTR register.

Set receive rule table write enable/disable using the AFLDAE bit.

Figure 21.19 shows the receive rule setting procedure.

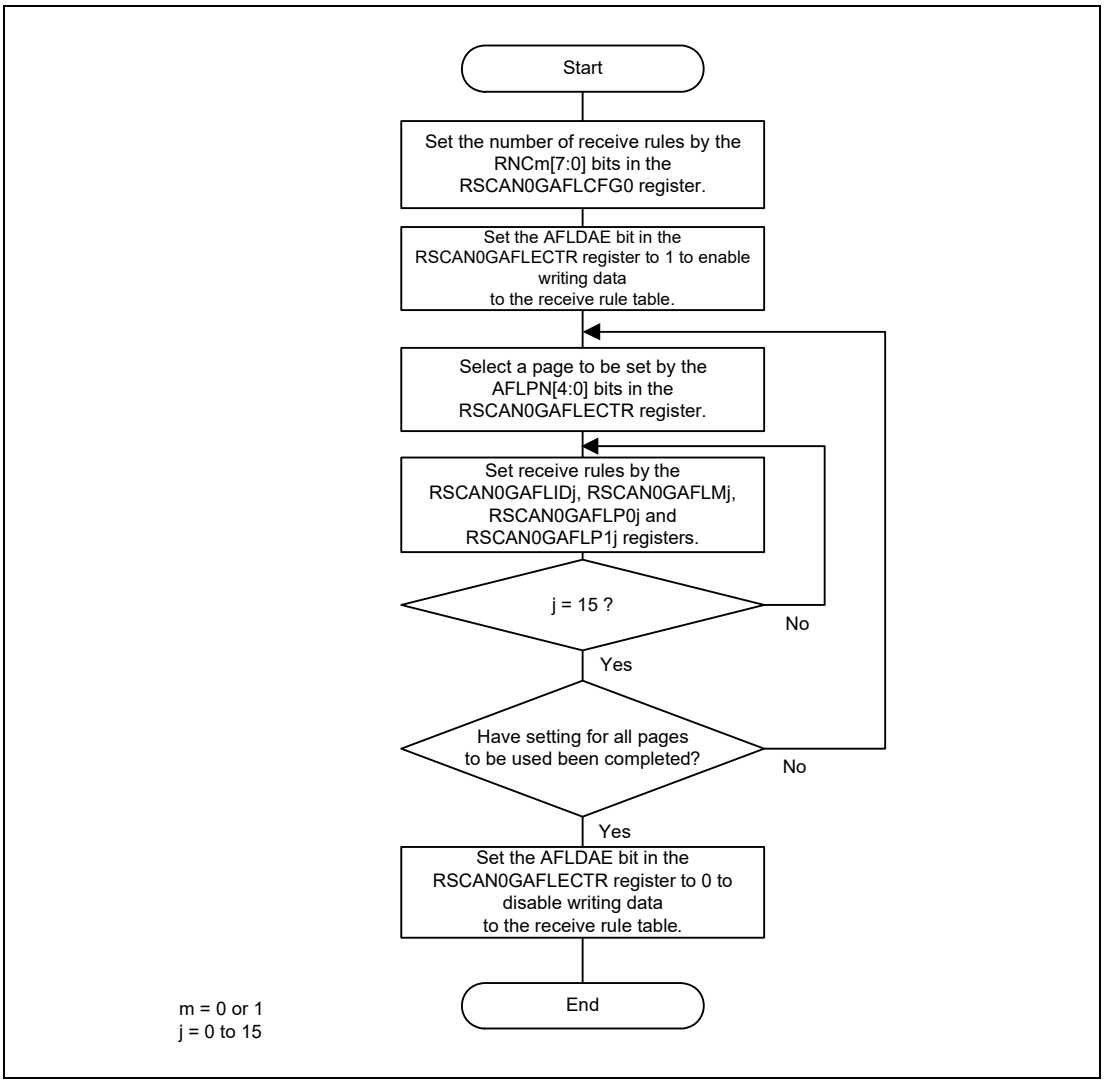

Figure 21.19 Receive Rule Setting Procedure

21.10.1.5 Buffer Setting

Set sizes and interrupt sources of buffers. For transmit/receive FIFO buffers that are set to transmit mode, set transmit buffers to be linked.

Figure 21.20 shows the buffer configuration. Figure 21.21 shows the buffer setting procedure.

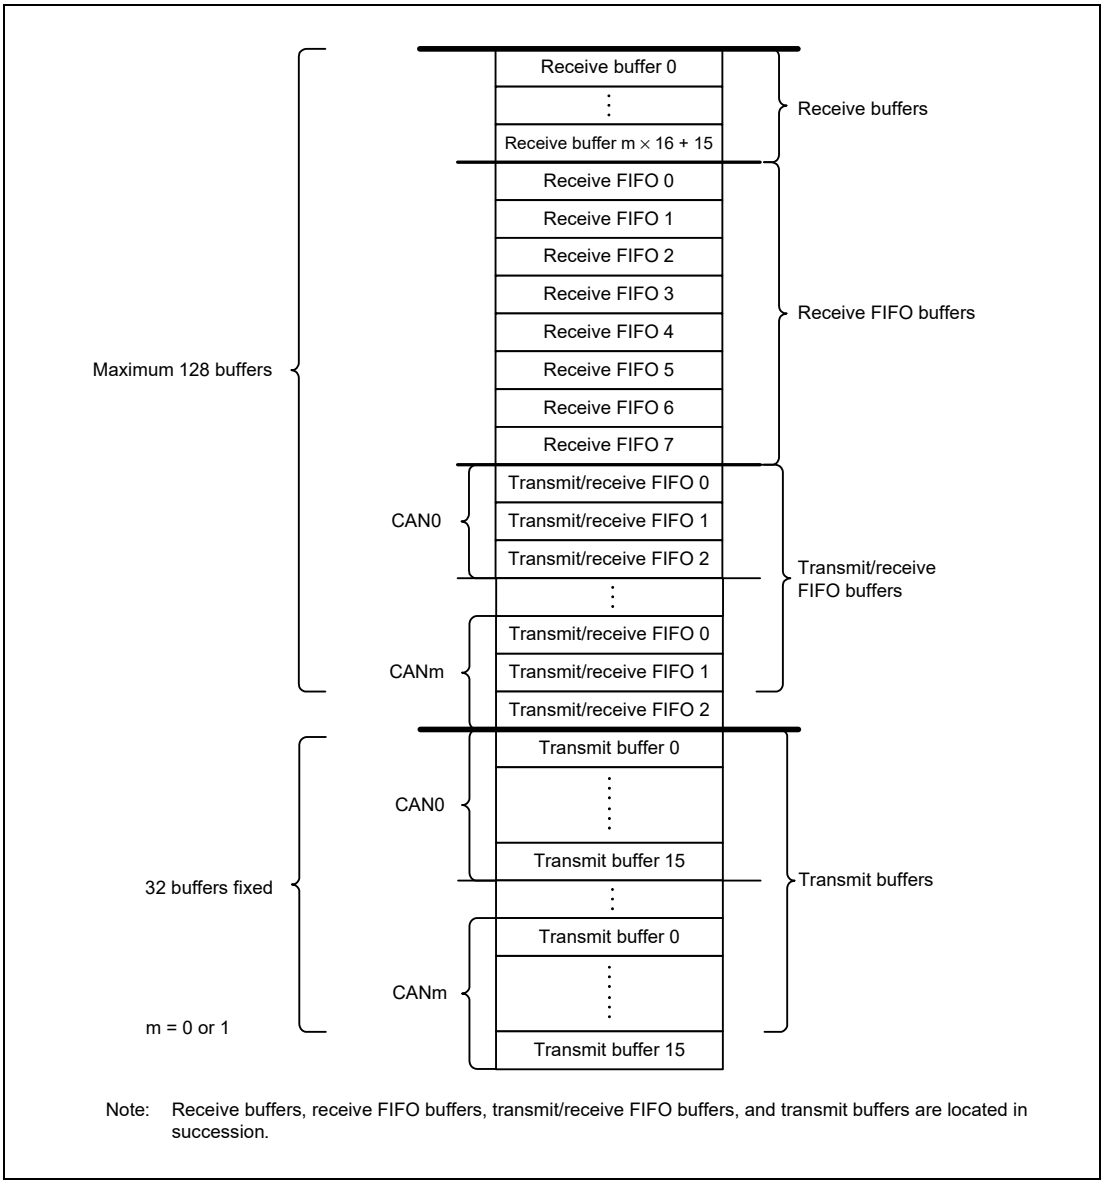

Figure 21.20 Buffer Configuration

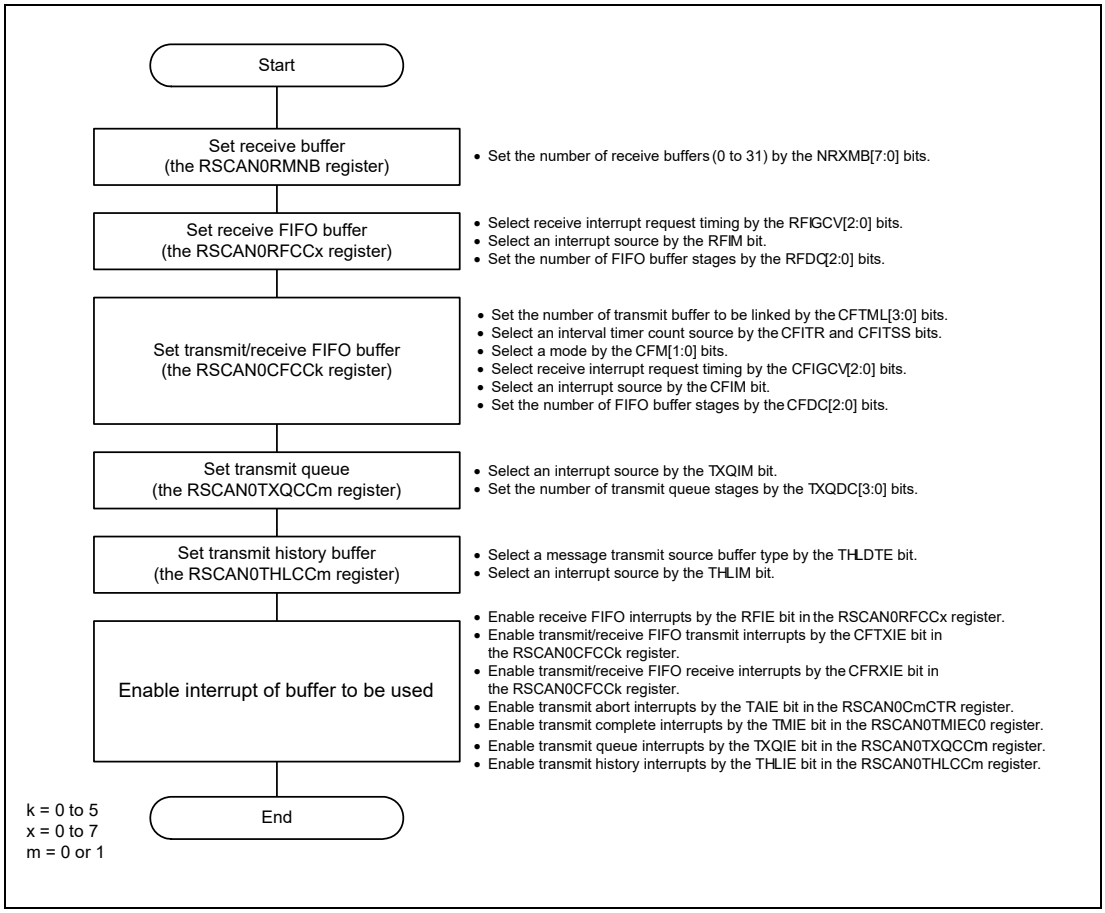

Figure 21.21 Buffer Setting Procedure

21.10.2 Reception Procedure

21.10.2.1 Receive Buffer Reading Procedure

When the processing to store received messages in a receive buffer starts, the RMNSq flag in the RSCAN0RMNDy register (y = 0, q = 0 to 31) is set to 1 (receive buffer q contains a new message). Messages can be read from the RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers. If the next message has been received before the current message is read from the receive buffer, the message is overwritten. Figure 21.22 shows the receive buffer reading procedure.

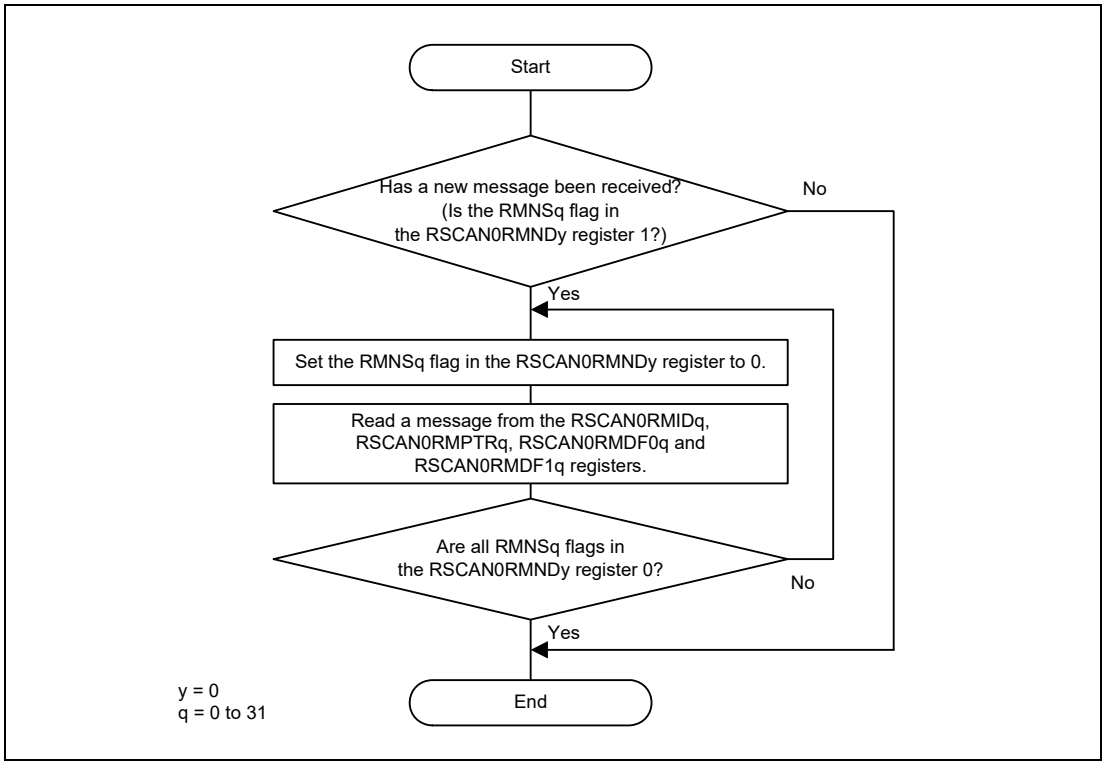

Figure 21.22 Receive Buffer Reading Procedure

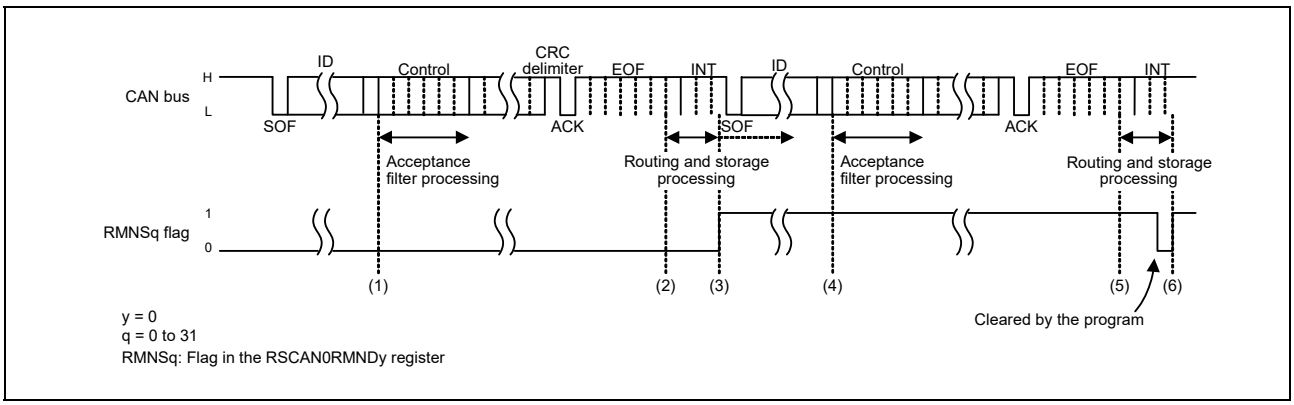

Figure 21.23 Receive Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.

(2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing, the processing to store the message in the specified receive buffer starts.
When the message storage processing starts, the RMNSq flag in the corresponding the RSCAN0RMNDy register is set to 1 (receive buffer n contains a new message). If other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(6) When the corresponding RMNSq flag is cleared to 0 (receive buffer n contains no new message), this flag is set to 1 again when the message storage processing starts. Even if the RMNSq flag remains 1, a new message is overwritten to the receive buffer. The RMNSq flag should not be cleared to 0 during storage of messages.

21.10.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more receive FIFO buffers or a transmit/receive FIFO buffer that is set to receive mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCAN0RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCAN0CFSTSk register (k = 0 to 5)) is incremented. At this time, when the RFIE bit (receive FIFO interrupt is enabled) in the RSCAN0RFCCx register or the CFRXIE bit (transmit/receive FIFO receive interrupt is enabled) in the RSCAN0CFCCk register is set to 1, an interrupt request is generated. Received messages can be read from the RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers for receive FIFO buffers, or from the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers for transmit/receive FIFO buffers. Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCAN0RFCCx register or the CFDC[2:0] bits in the RSCAN0CFCCk register), the RFFLL or CFFLL flag is set to 1 (the receive FIFO buffer is full).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCAN0RFSTSx register or the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no receive FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCAN0RFSTSx register or CFRXIF flag in the RSCAN0CFSTSk register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. The program must clear the interrupt request flag to 0.

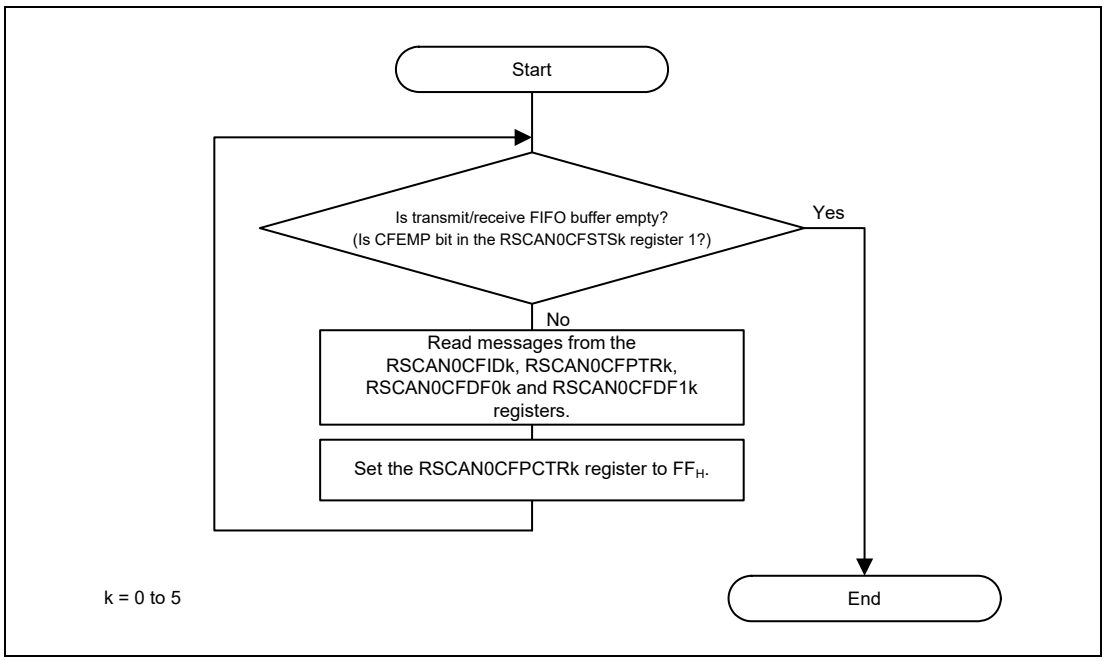

Figure 21.24 Transmit/Receive FIFO Buffer Reading Procedure

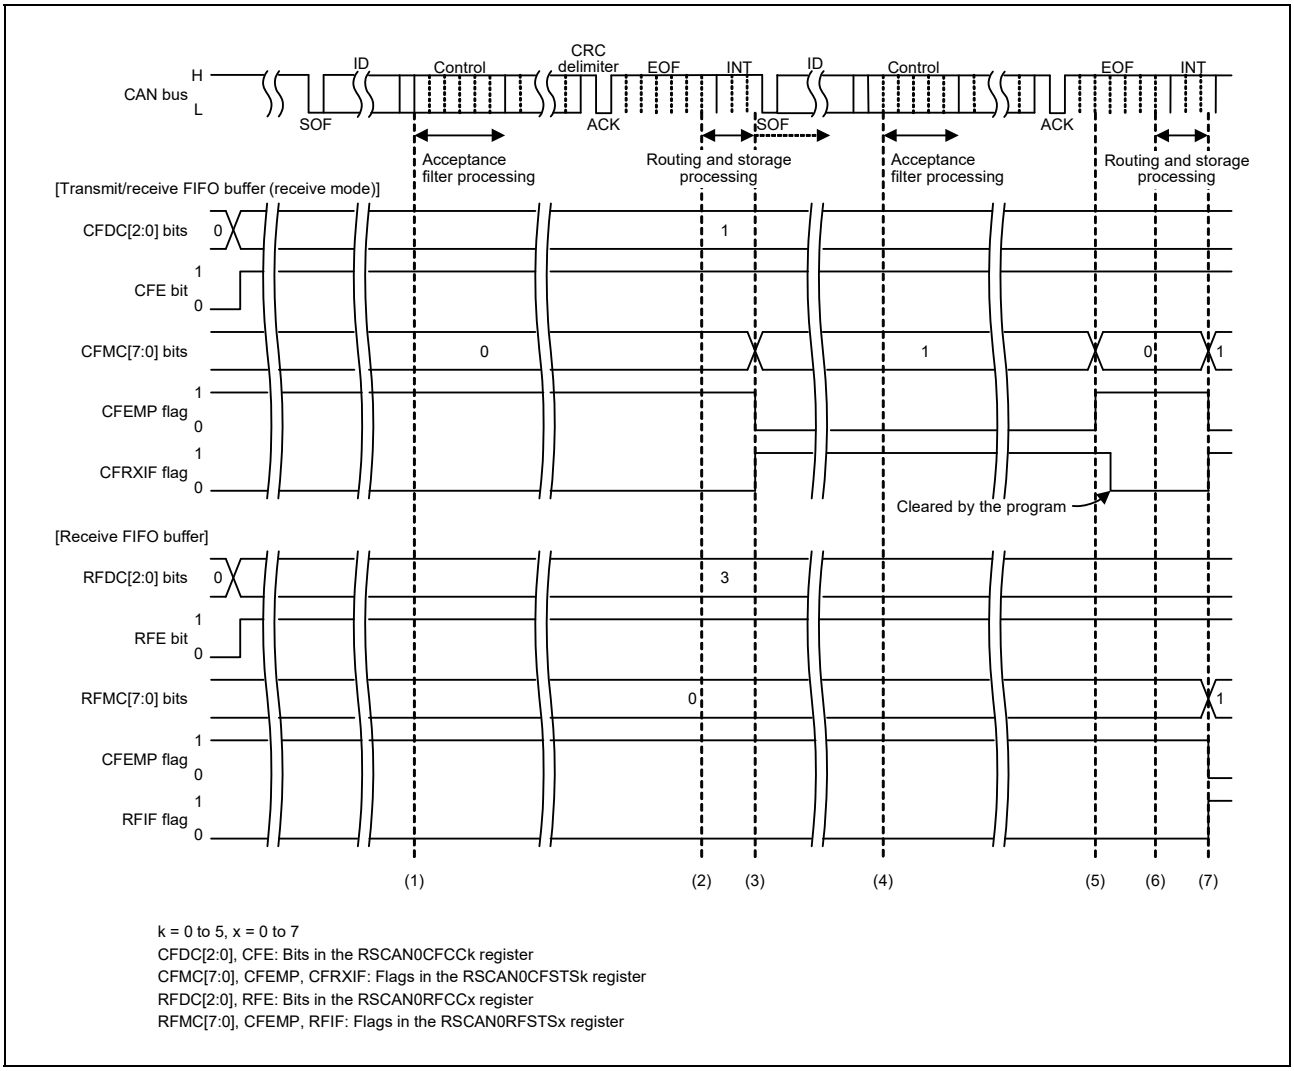

Figure 21.25 FIFO Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.

(2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing and the CFE value in the RSCAN0CFCCk register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCk register is 001_B or more, the message is stored in the transmit/receive FIFO buffer that is set to receive mode. The CFMC[7:0] value in the RSCAN0CFSTSk register is incremented and becomes 01_H. When the CFIM bit in the RSCAN0CFCCk register is set to 1 (a FIFO receive interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). The CFRXIF flag can be reset to 0 by the program.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) Read received messages from the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers and write FF_H to the RSCAN0CFPCTRk register. This causes the CFMC[7:0] bits in the RSCAN0CFSTSk register to be decremented. When CFMC[7:0] becomes 00_H, the CFEMP flag in the RSCAN0CFSTSk register becomes 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

(6) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(7) The message is stored in the transmit/receive FIFO buffer set in receive mode when the message has passed through the DLC filter process if the CFE bit is set to 1 (transmit/receive FIFO buffers are used), the RFE bit in the RSCAN0RFCCx register is set to 1, and the CFDC[2:0] bits are set to 001_B or more. The CFMC[7:0] bit value is incremented by 1 to be 01_H. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO receive interrupt request is present).
The message is stored in the receive FIFO buffer if the RFE bit in the RSCAN0RFCCx register is set to 1 (receive FIFO buffers are used), and the RFDC[2:0] bits in the RSCAN0RFCCx register are set to 001_B or more. The RFMC[7:0] bits in the RSCAN0RFSTSx register are set to 01_H by being incremented by 1. When the RFIM bit in the RSCAN0RFCCx register is set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present).

21.10.3 Transmission Procedure

21.10.3.1 Procedure for Transmission from Transmit Buffers

Figure 21.26 shows the procedure for transmission from transmit buffers.

Figure 21.27 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmission has been successfully completed. Figure 21.28 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmit abort has been completed.

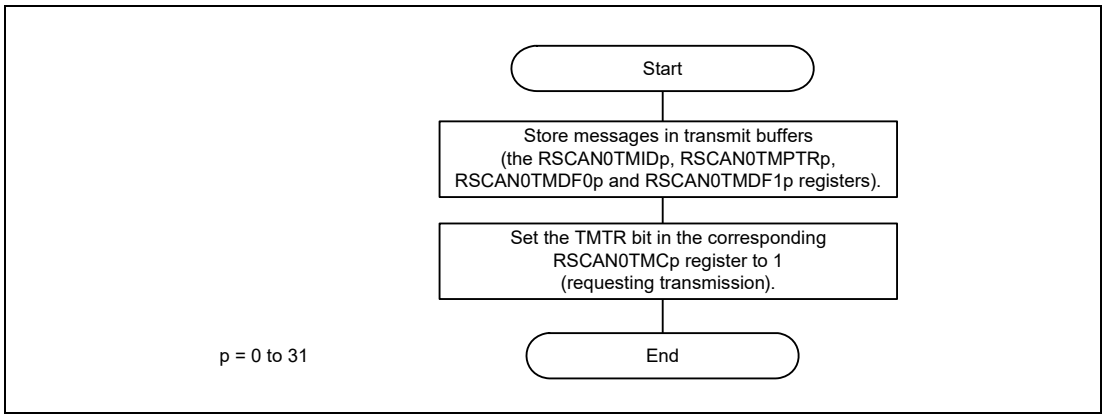

Figure 21.26 Procedure for Transmission from Transmit Buffers

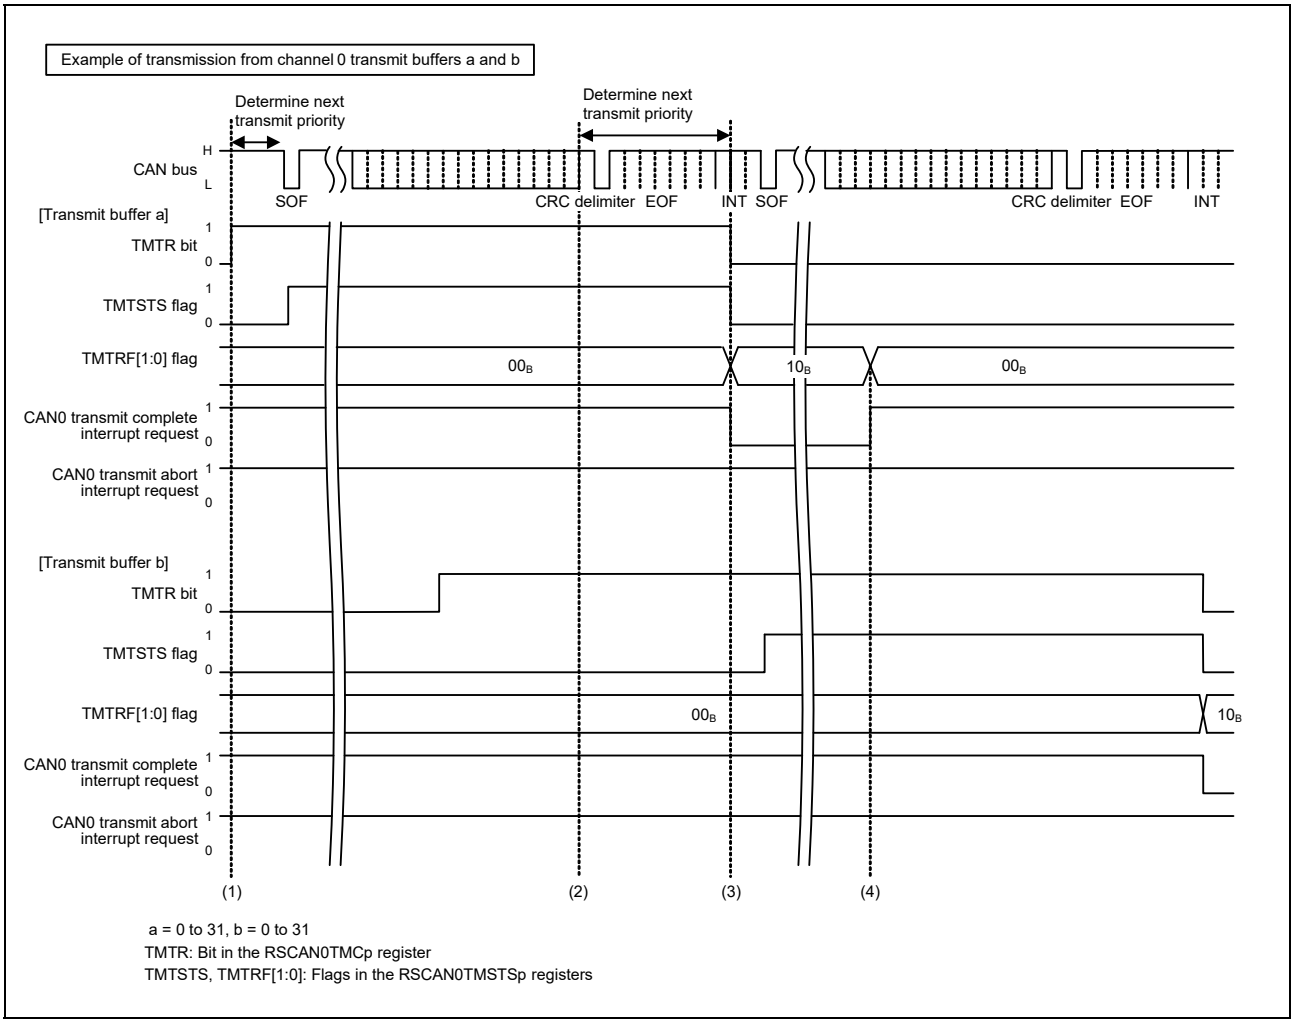

Figure 21.27 Transmit Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding the RSCAN0TMCa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission.

(3) When transmission completes successfully, the TMTRF[1:0] flag in the RSCAN0TMCa register is set to 10_B (transmission has been completed (without transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMCa register are cleared to 0. When the TMIEa value in the RSCAN0TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).

(4) Before starting the next transmission, set the TMTRF[1:0] flag to 00_B. Write the next message to the transmit buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is 00_B.

If an arbitration-lost has occurred after transmission is started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.

The timing the TMTSTS flag is set to 1 is not always the start timing of SOF. The start timing of SOF can be delayed up to the start timing of the basic ID due to the synchronization logic implemented for PLL bypass.

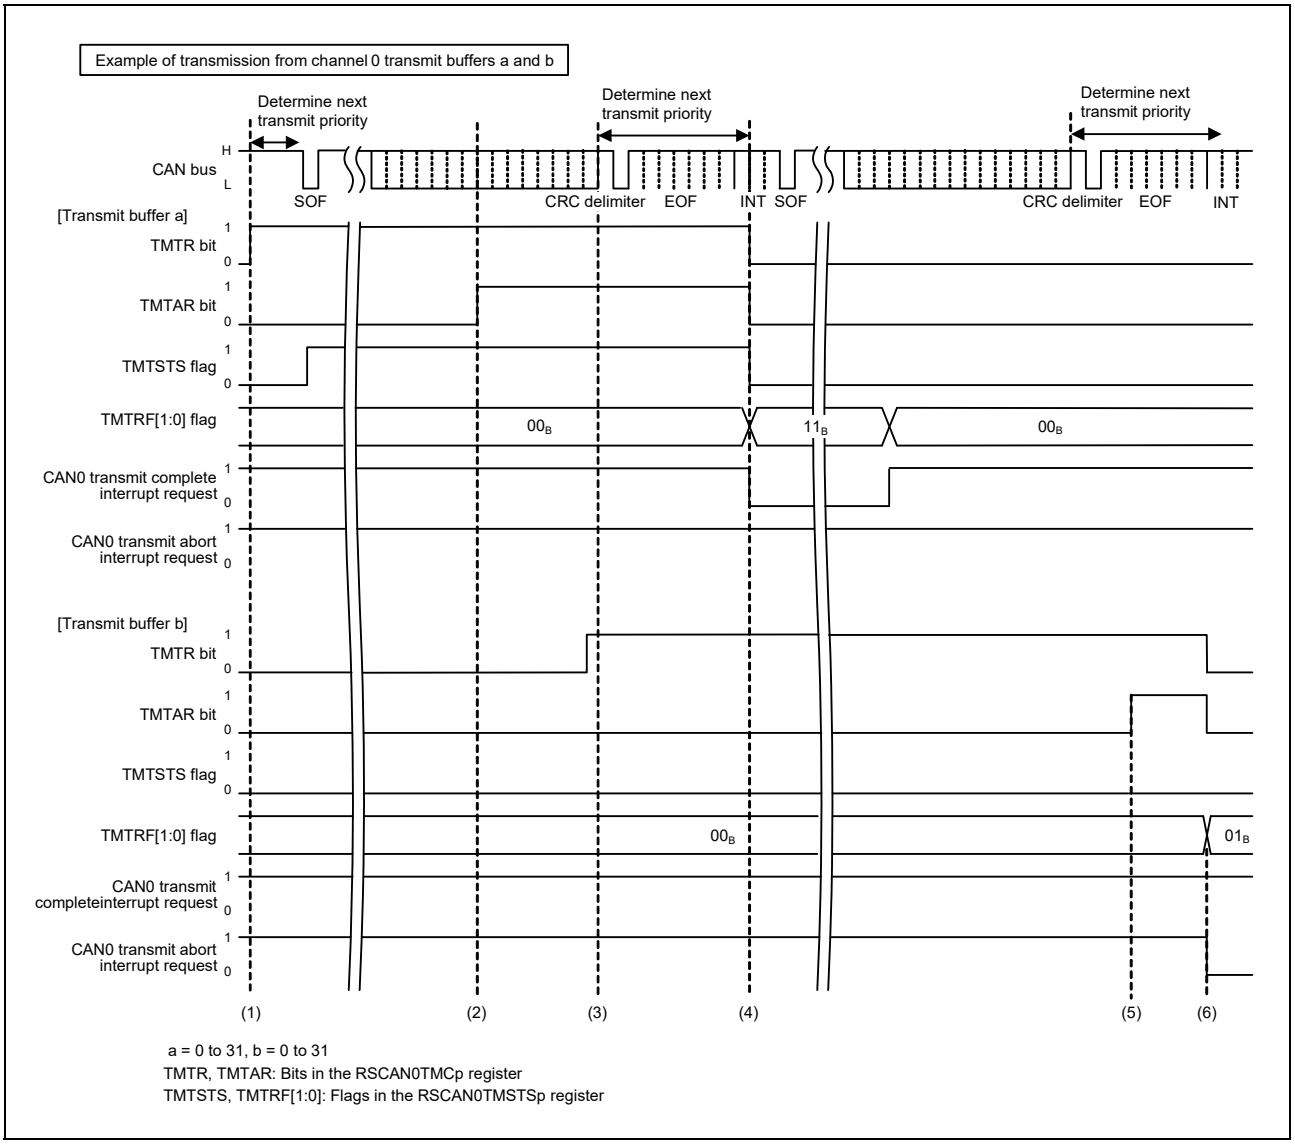

Figure 21.28 Transmit Buffer Transmission Timing Chart (Transmit Abort Completed)

(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCAN0TMCa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When it is determined that the transmit buffer is used for the next transmission or transmission is in progress, message transmission is not aborted unless an error or arbitration loss occurs even if the TMTAR bit is set to 1 (transmit abort is requested).

(3) The priority determination starts with the CRC delimiter for the next transmission. In this timing chart, buffer b is not selected as the next transmit buffer.

(4) When transmission completes successfully, the TMTRF[1:0] flag in the RSCAN0TMCa register is set to 11_B (transmission has been completed (with transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMCa register are cleared to 0. When the TMIEa value in the RSCAN0TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).

(5) While another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority, the TMTR bit cannot be cleared to 0.

(6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to 01_B. When the transmit buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to 01_B. At this time, the TMTR and TMTAR bits are cleared to 0. When transmit abort is completed with the TAIE bit in the RSCAN0CmCTR register set to 1 (transmit abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B.

If an arbitration loss has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to find the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.

21.10.3.2 Procedure for Transmission from Transmit/Receive FIFO Buffers

Figure 21.29 shows the procedure for transmission from transmit/receive FIFO buffers.

Figure 21.30 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmission has been successfully completed. Figure 21.31 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmit abort has been completed.

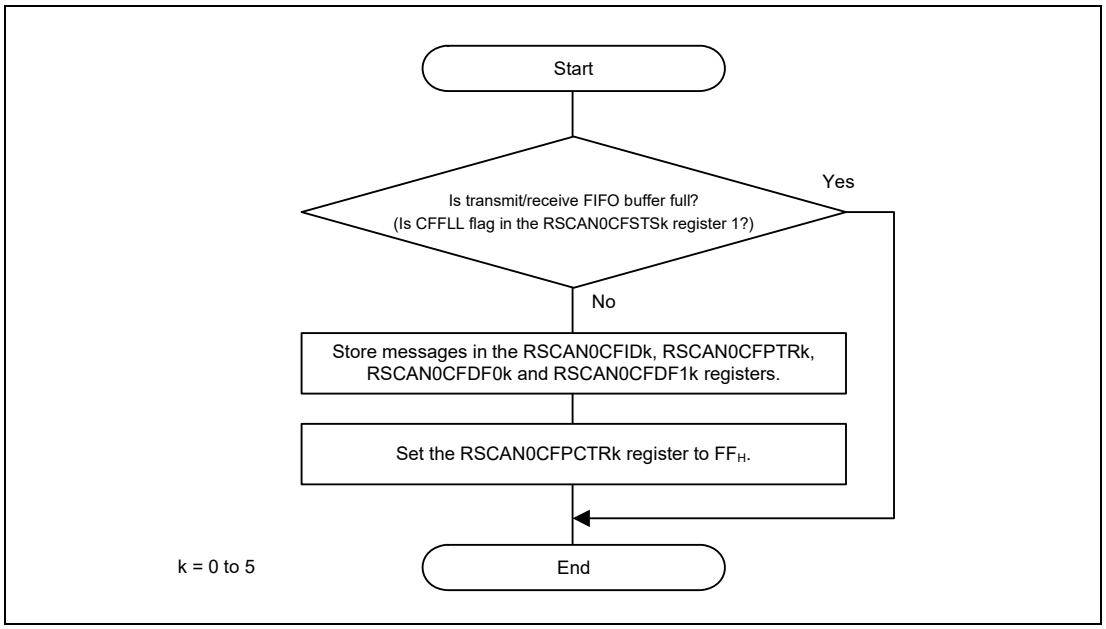

Figure 21.29 Procedure for Transmission from Transmit/Receive FIFO Buffers

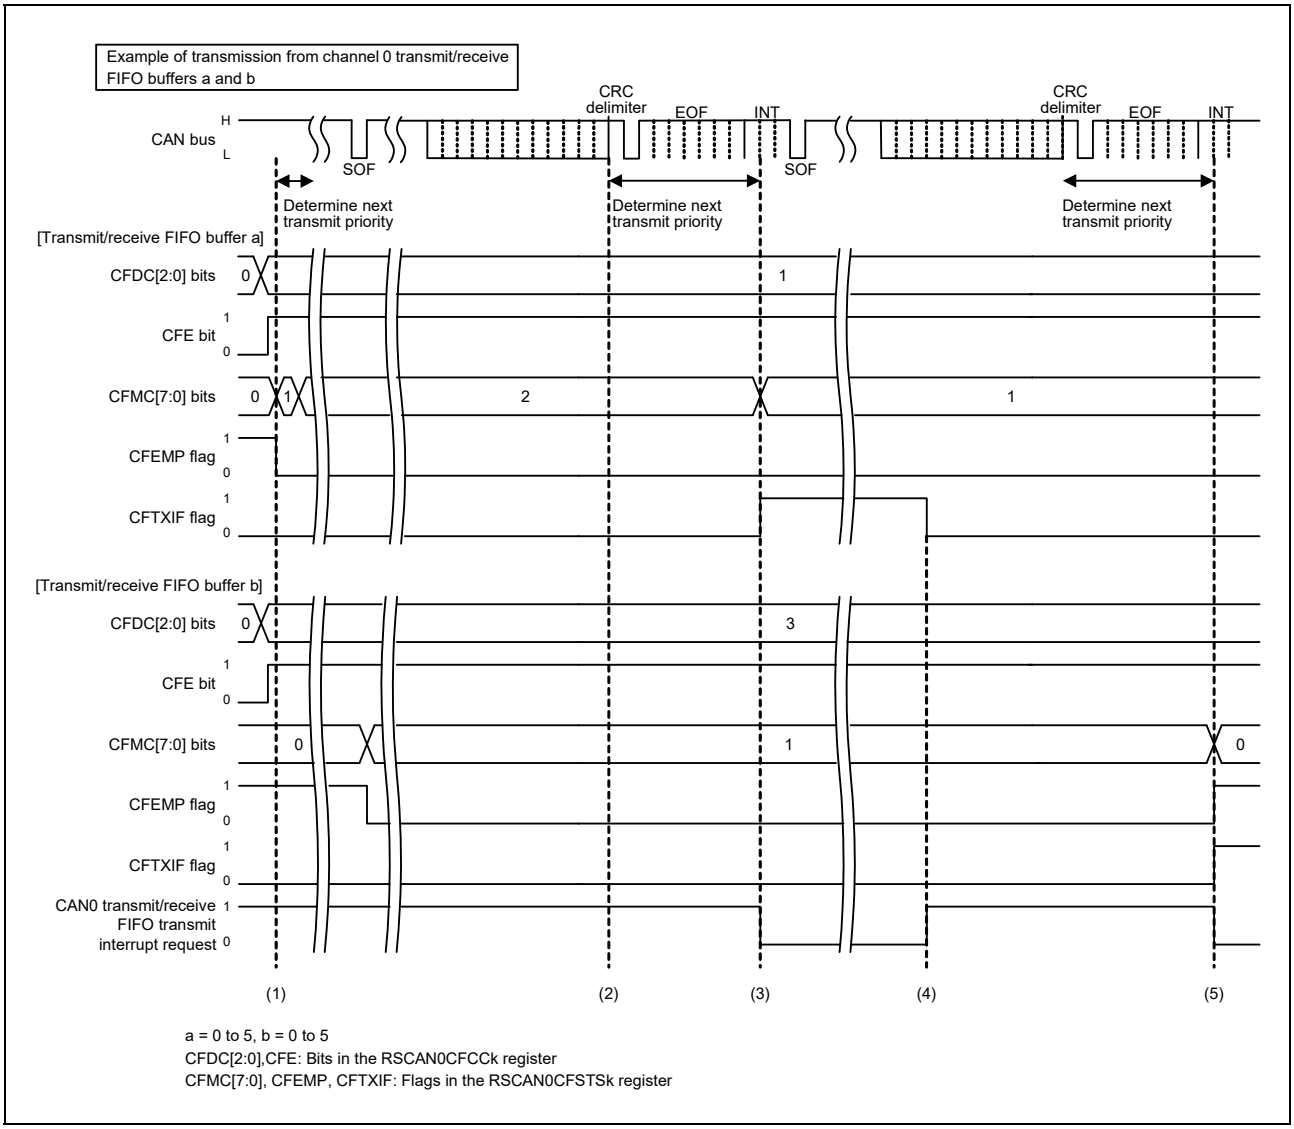

Figure 21.30 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) While the CAN bus is idle, when the CFE value in the RSCA0CFCCa register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCa register is 001_B (4 messages) or more and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01_H or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission.

(3) When transmission completes successfully, the CFMC[7:0] value in the RSCAN0CFSTSa register is decremented. Setting the CFIM bit in the RSCAN0CFCCa register to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSk register to 1 (a transmit/receive FIFO transmit interrupt request is present).

(4) The program can clear the CFTXIF flag.

(5) Message transmission from transmit/receive FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCAN0CFSTSb register is decremented. The CFMC[7:0] bits are cleared to 00_H and therefore the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store transmit messages in FIFO buffers until the CFFLL flag in the RSCAN0CFSTSa and RSCAN0CFSTSb register is set to 1 (the transmit/receive FIFO buffer is full).

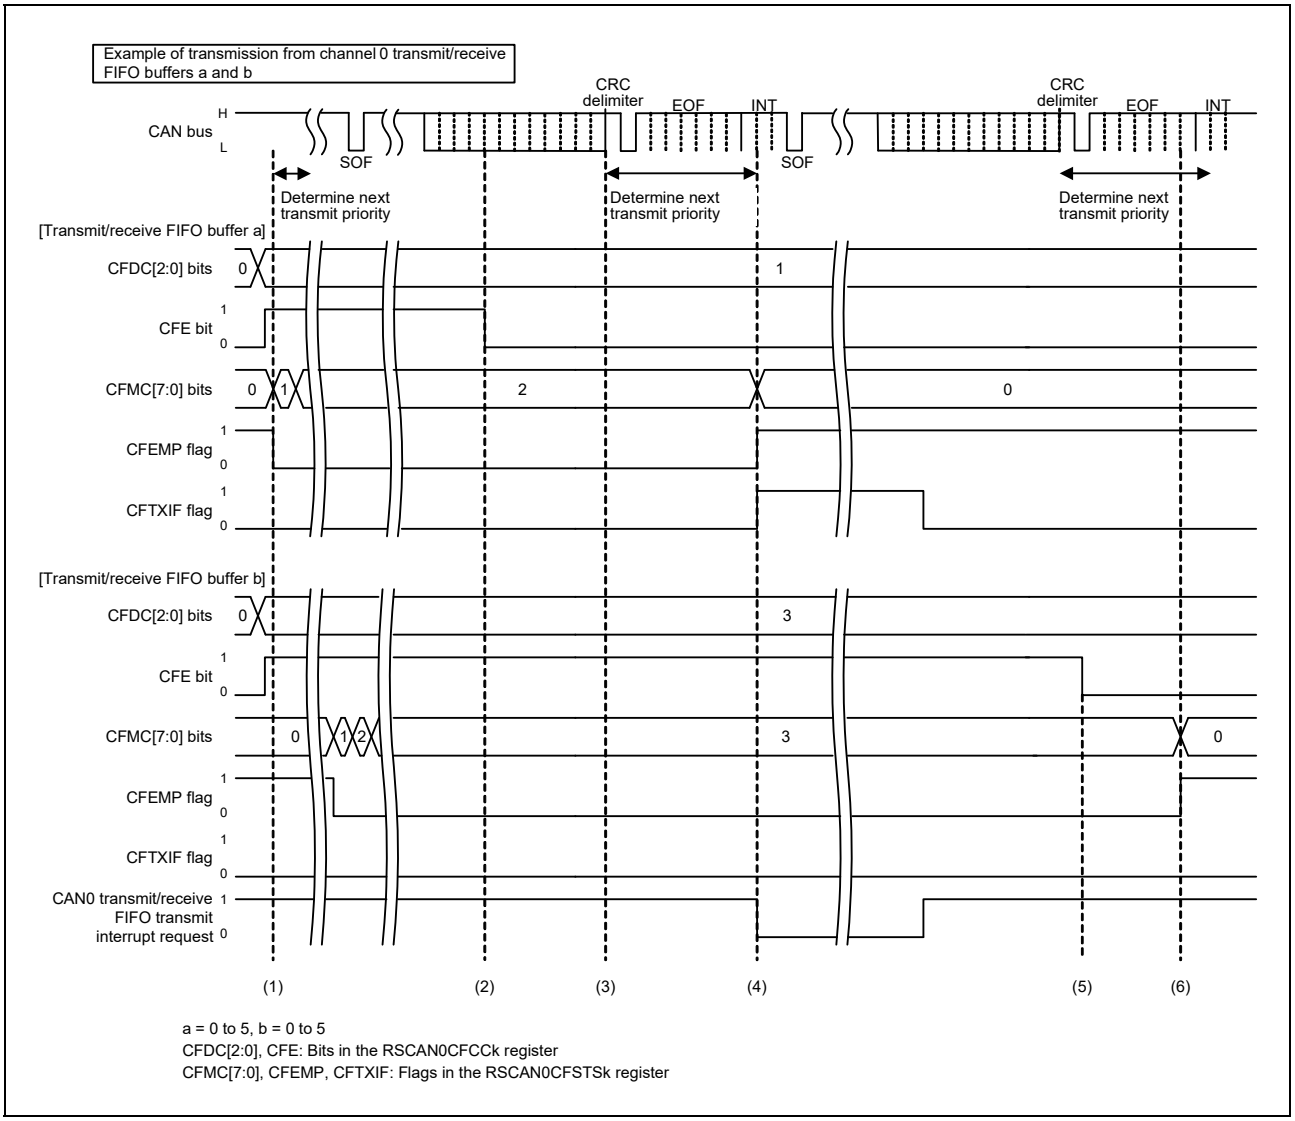

Figure 21.31 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmit Abort Completed)

(1) While the CAN bus is idle, when the CFE value in the RSCAN0CFCCa register (a = 0 to 5) is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCa register is 001_B (4 messages) or more and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01_H or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

(2) When transmission is in progress or it is determined that the transmit/receive FIFO buffer is used for the next transmission, message transmission is not aborted unless an error or arbitration loss occurs even if the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

(3) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. In this figure, transmit/receive FIFO buffer b is not selected as a buffer for the next transmission.

(4) When transmit completes successfully, the CFMC[7:0] value is cleared to 00_H. Setting the CFIM bit to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSa register to 1 (a transmit/receive FIFO transmit interrupt request is present). The program can clear the CFTXIF flag.

(5) If another CAN node on the CAN bus is transmitting data (not from transmit/receive FIFO buffer b), transmit/receive FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCAN0CFCCb register is cleared to 0 (no transmit/receive FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCAN0CFSTSb register is not set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) immediately.)

(6) After the internal processing time has passed, transmit/receive FIFO buffers are disabled and the CFMC[7:0] bits in the RSCAN0CFSTSb register are cleared to 00_H and the CFEMP flag is set to 1. When the transmit/receive FIFO buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not in progress, the transmit/receive FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to 00_H and the CFEMP flag is set to 1.)

21.10.3.3 Procedure for Transmission from the Transmit Queue

Figure 21.32 shows the procedure for transmission from the transmit queue.

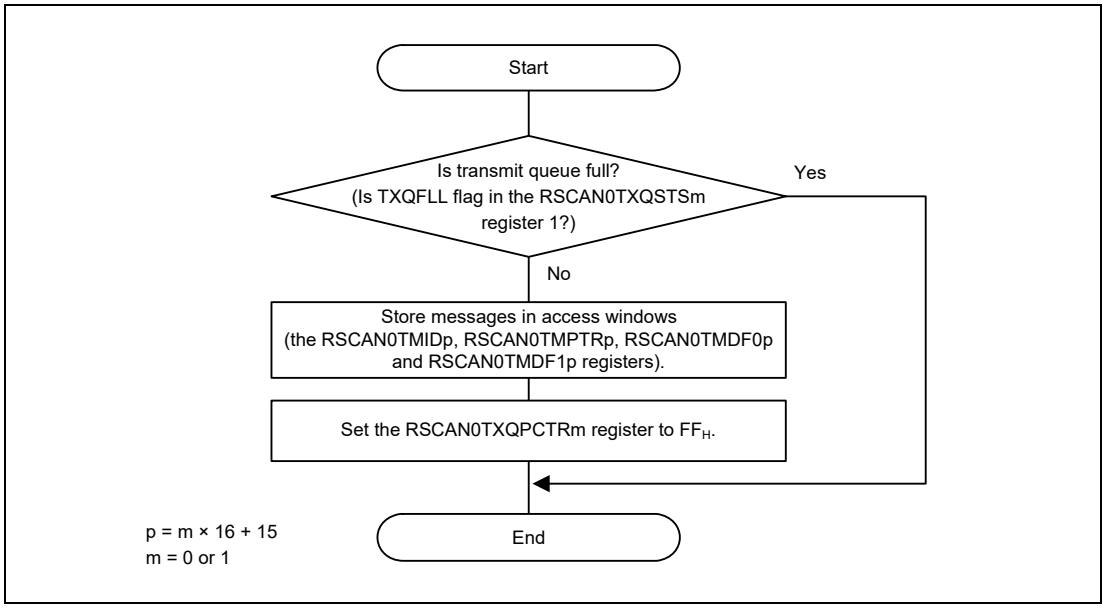

Figure 21.32 Procedure for Transmission from the Transmit Queue

21.10.3.4 Transmit History Buffer Reading Procedure

Transmit history data can be read from the RSCAN0THLACCm register. The next data can be accessed by writing FF_H to the corresponding RSCAN0THLPCTRm register (m = 0 or 1) after reading a set of data. Figure 21.33 shows the transmit history buffer reading procedure.

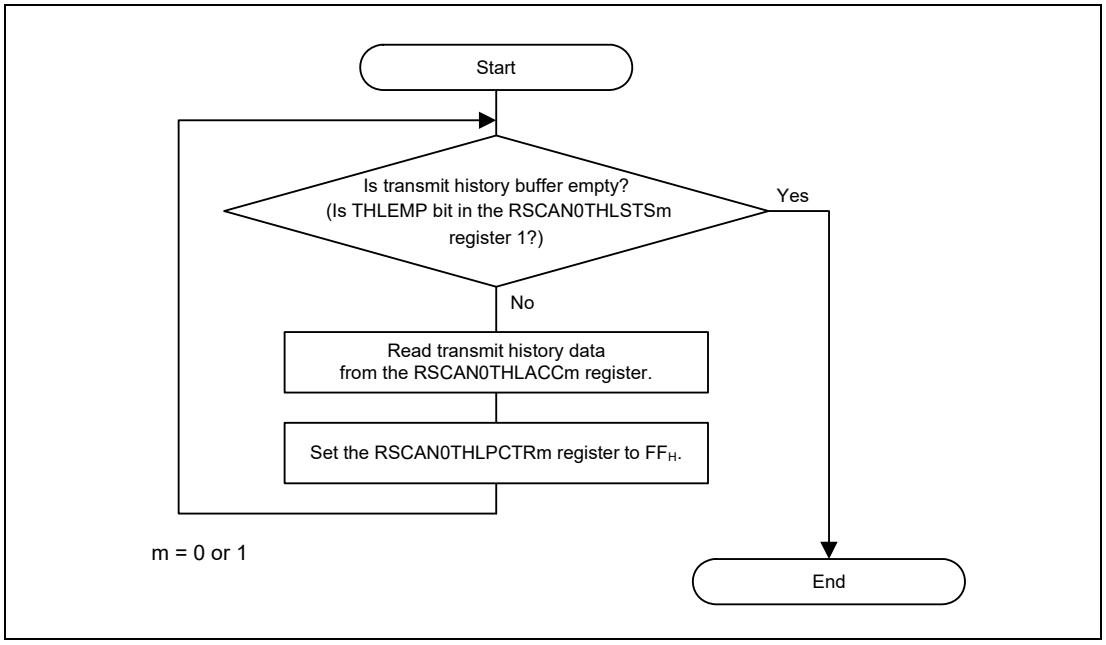

Figure 21.33 Transmit History Buffer Reading Procedure

21.10.4 Test Settings

21.10.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by enabling a CAN node to receive its own transmitted messages.

Figure 21.34 shows the self-test mode setting procedure.

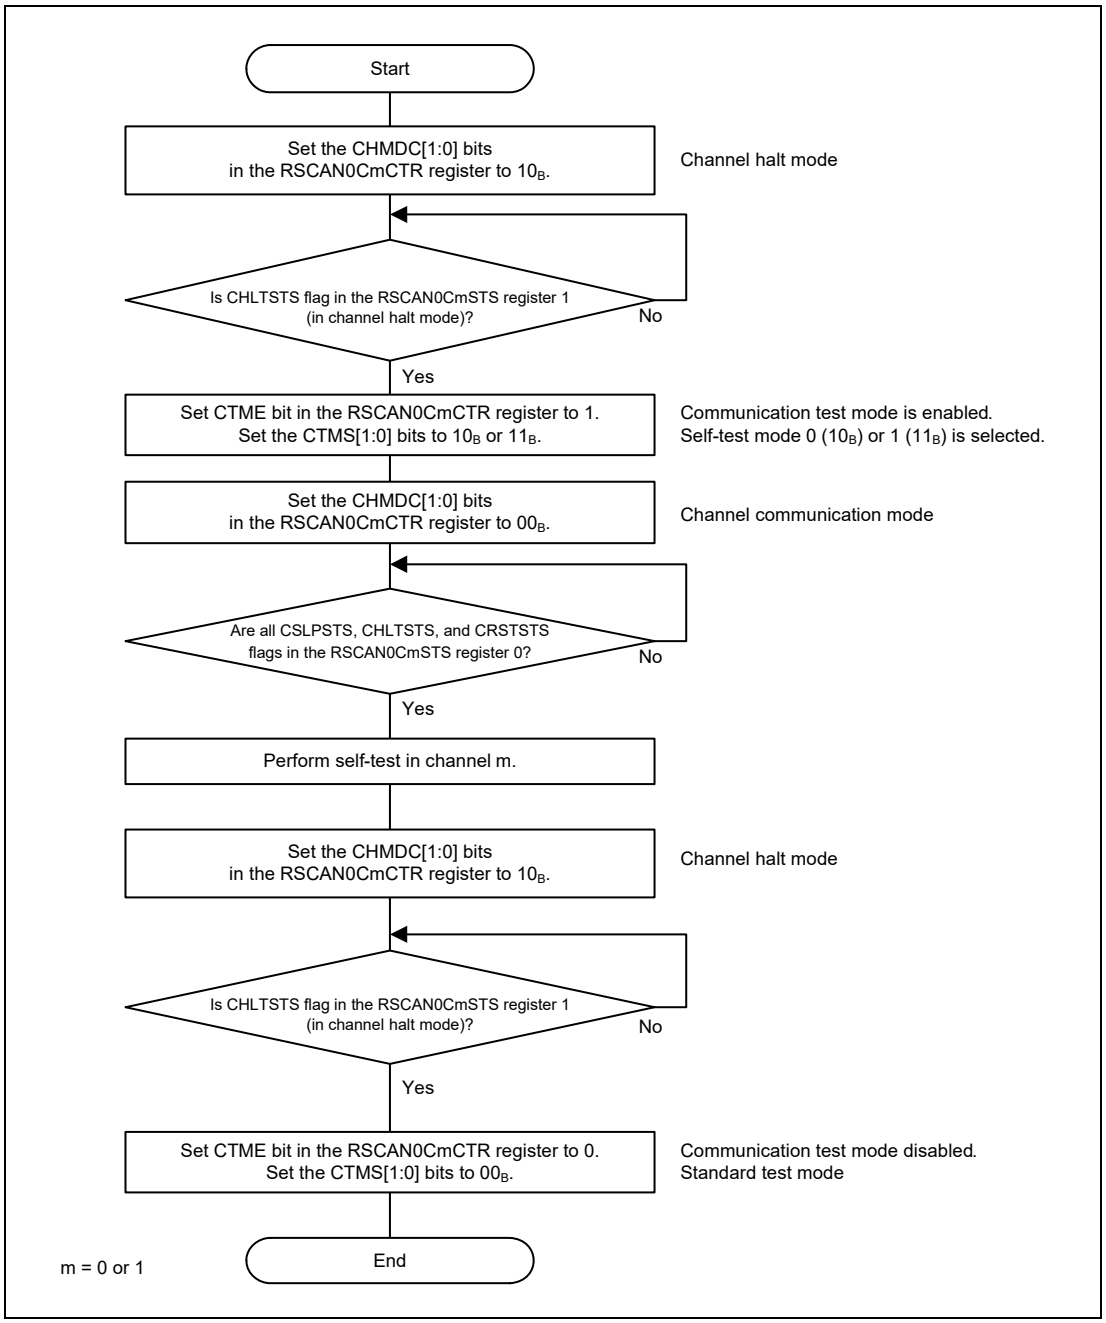

Figure 21.34 Self-Test Mode Setting Procedure

21.10.4.2 Inter-Channel Communication Test Setting Procedure

Communication testing can be performed by transmitting and receiving data between different channels.

Figure 21.35 shows the inter-channel communication test setting procedure.

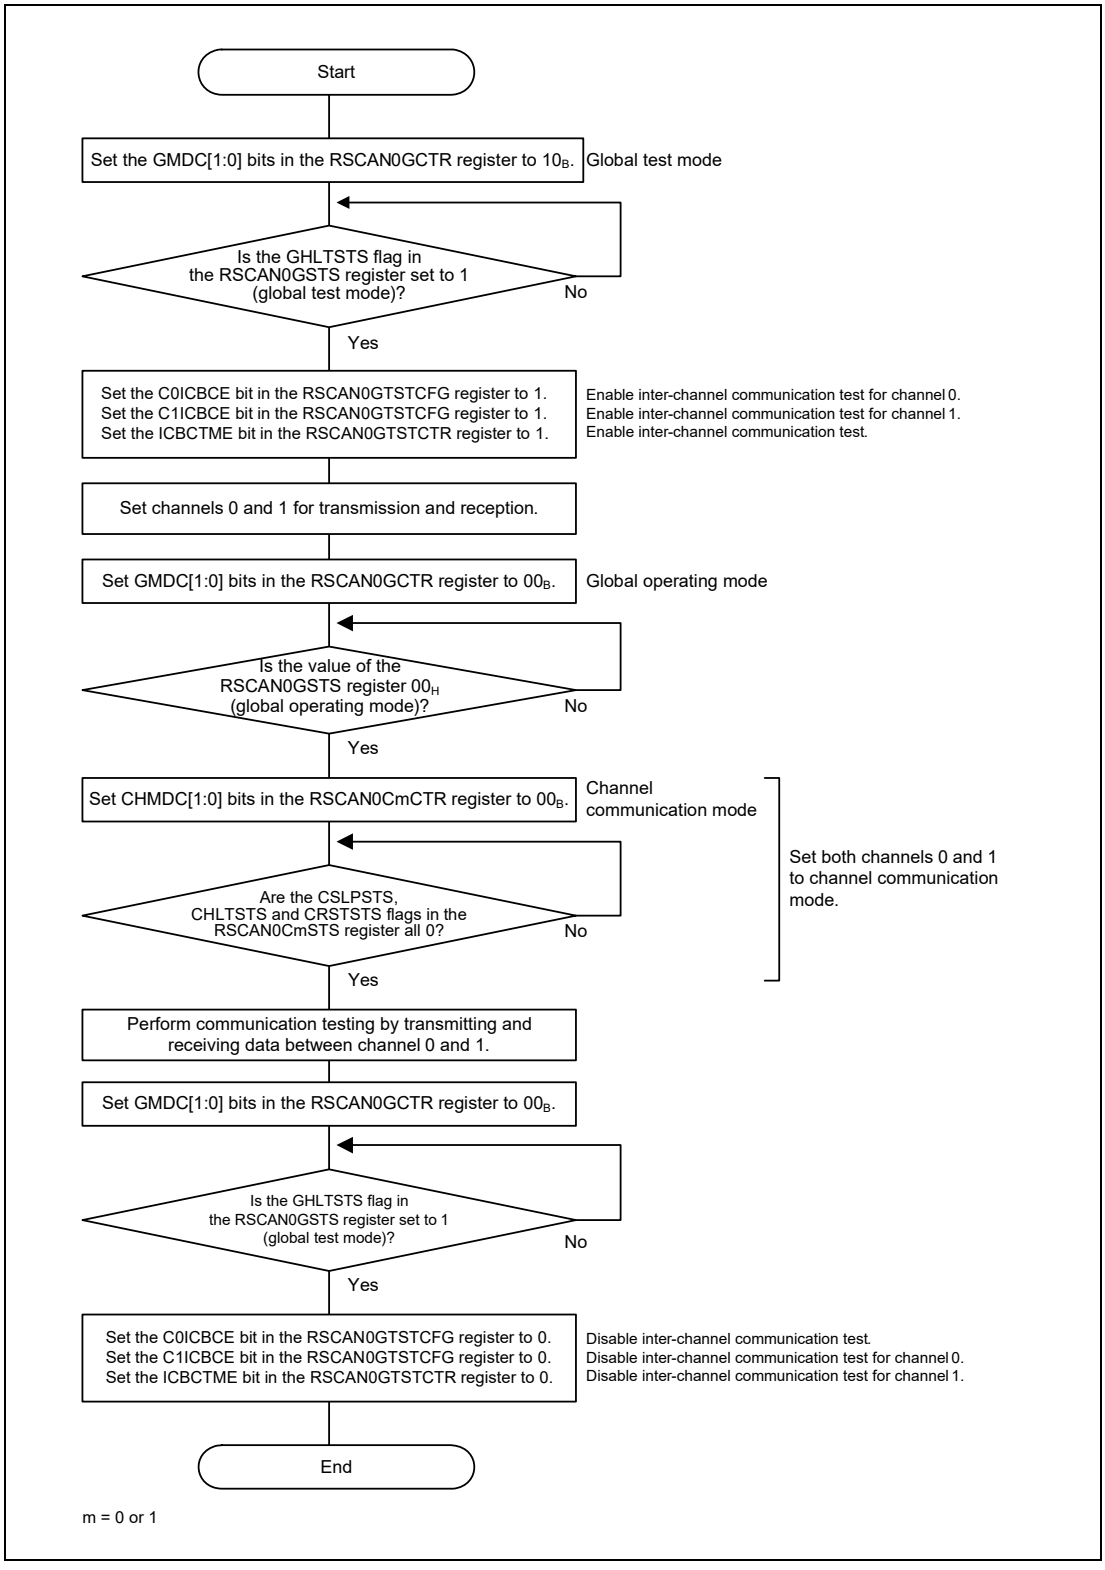

Figure 21.35 Inter-Channel Communication Test Setting Procedure(Example of Communication Test between Channel 0 and Channel 1)

21.11 Notes on the RS-CAN Module

- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCAN0GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCAN0CmSTS register (m = 0 or 1) for transitions.
- The acceptance filter processing checks receive rules sequentially in ascending order from the minimum rule number. If the same ID, IDE bit, or RTR bit value is set for multiple receive rules, the minimum number of receive rule is used for the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmit buffers to transmit/receive FIFO buffers or allocating transmit buffers to transmit queues, set the control register (RSCAN0TMCp) of the corresponding transmit buffer to 00_H. The status register (RSCAN0TMSTSp) of the corresponding transmit buffer should not be used. Flags in other status registers (registers RSCAN0TMTRSTS0, RSCAN0TMTARSTS0, RSCAN0TMTCSTS0, and RSCAN0TMTASTS0), which correspond to transmit buffers linked to transmit/receive FIFO buffers or allocated to transmit queues remain unchanged. Set the enable bit in the corresponding interrupt enable register (the RSCAN0TMIEC0 register) to 0 (transmit buffer interrupt is disabled).
- Transmit buffers that are linked to transmit/receive FIFO buffers must not bet allocated to transmit queues.
- Only a single transmit/receive FIFO buffer can be linked to a transmit buffer. Do not link two or more transmit/receive FIFO buffers to transmit buffers of the same number.
- When the CANm bit time clock is selected as a timestamp counter clock source, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- In case of an attempt to store a new received message when the receive FIFO buffer and the transmit/receive FIFO buffer are full, the new message is discarded. If you wish to store a new transmit message in the transmit/receive FIFO buffer or the transmit queue, check that the transmit/receive FIFO buffer or the transmit queue is not full.
- The values of unused receive buffer registers (RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers), receive FIFO buffer access registers (RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers), and transmit/receive FIFO buffer access registers (RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers) are undefined when the RS-CAN module transitions to global operation mode or global test mode after exiting from global reset mode.

22. IEBus Controller

This module is only incorporated in the RZ/A1L.

IEBus (Inter Equipment Bus) is a small-scale digital data transfer system that transfers data between units. To use IEBus with this LSI, an external IEBus driver and receiver are necessary because they are not provided.

The internal IEBus controller of this LSI is of negative logic.

22.1 IEBB Features

Channels This microcontroller has the following number of channels of the IEBB.

Table 22-1 Channels of IEBB

IEBB	
Number of channels	1
Name	IEBB0

Channel index n Throughout this chapter, the individual channels of IEBB are identified by the index "n" (n = 0), for example, IEBBnBCR for the IEBBn bus control register.

Register addresses All IEBBn register addresses are given as addresses offset from the base address <IEBBn_base>.

The base address <IEBBn_base> of each IEBBn is listed in the following table:

Table 22-2 Register base address <IEBBn_base>

IEBBn	<IEBBn_base>
IEBB0	FCFEF000

Clock supply The following clock is supplied to the IEBBn:

Table 22-3 IEBBn clock supply

IEBBn	Clock	Connected to:
IEBB0	P0ϕ	Clock pulse generator

Interrupts and DMA The IEBB can generate the following interrupt requests and DMA requests:

Table 22-4 IEBBn interrupts and DMA requests

Interrupt request signal	Function	Direct memory access controller activation
IEBBTD	Data interrupt request	√
IEBBTV	Vector interrupt request	√
IEBBTERR	Error interrupt request	—
IEBBTSTA	Status interrupt request	—

I/O signals The I/O signals of the IEBB0 are listed in the following table:

Table 22-5 IEBBn I/O signals

Pin name	Function	Input/output
IERxD	IEBB0 reception data	Input
IETxD	IEBB0 transmission data	Output

22.2 Configuration

22.2.1 Function overview

Features summary

- **The data transfer system complies with the IEBus (communication mode 1/ communication mode 2) protocol.**
- **The IEBus (Inter Equipment Bus) controller is mainly intended to transfer data between automotive devices by using a two-line serial bus interface.**
- Effective transmission speed: Approximately 18 kbps (communication mode 1), or approximately 27 kbps (communication mode 2)
- The single mode or FIFO mode can be selected.
- Maximum number of transferred bytes:

  32 bytes/frame (communication mode 1)
  128 bytes/frame (communication mode 2)
- To implement IEBus, an external IEBus driver and receiver are necessary. The driver and receiver are not built in.
- This IEBus controller uses negative logic.
- Operation clock: 8 MHz (input P0ϕ = 32 MHz to this module)
- Interrupt request signals
  - Data interrupt (IEBBTD)

    For transmission data write processing (single mode, FIFO mode)

    For reception data read processing (single mode)
  - Error interrupt (IEBBTERR)

    For error processing
  - Status interrupt (IEBBTSTA)

    Start interrupt processing (single mode)

    Status transmission interrupt (single mode)

    Communication completion interrupt (single mode, FIFO mode)

    Frame completion interrupt (single mode, FIFO mode)
  - Vector interrupt (IEBBTV)

    Occurs at the same time as IEBBTERR or IEBBTSTA (single mode)

    For reception data read processing (FIFO mode)
- Pin configuration
  - IERxD: IEBus reception data input signal
  - IETxD: IEBus transmission data output signal

22.2.2 Block diagram

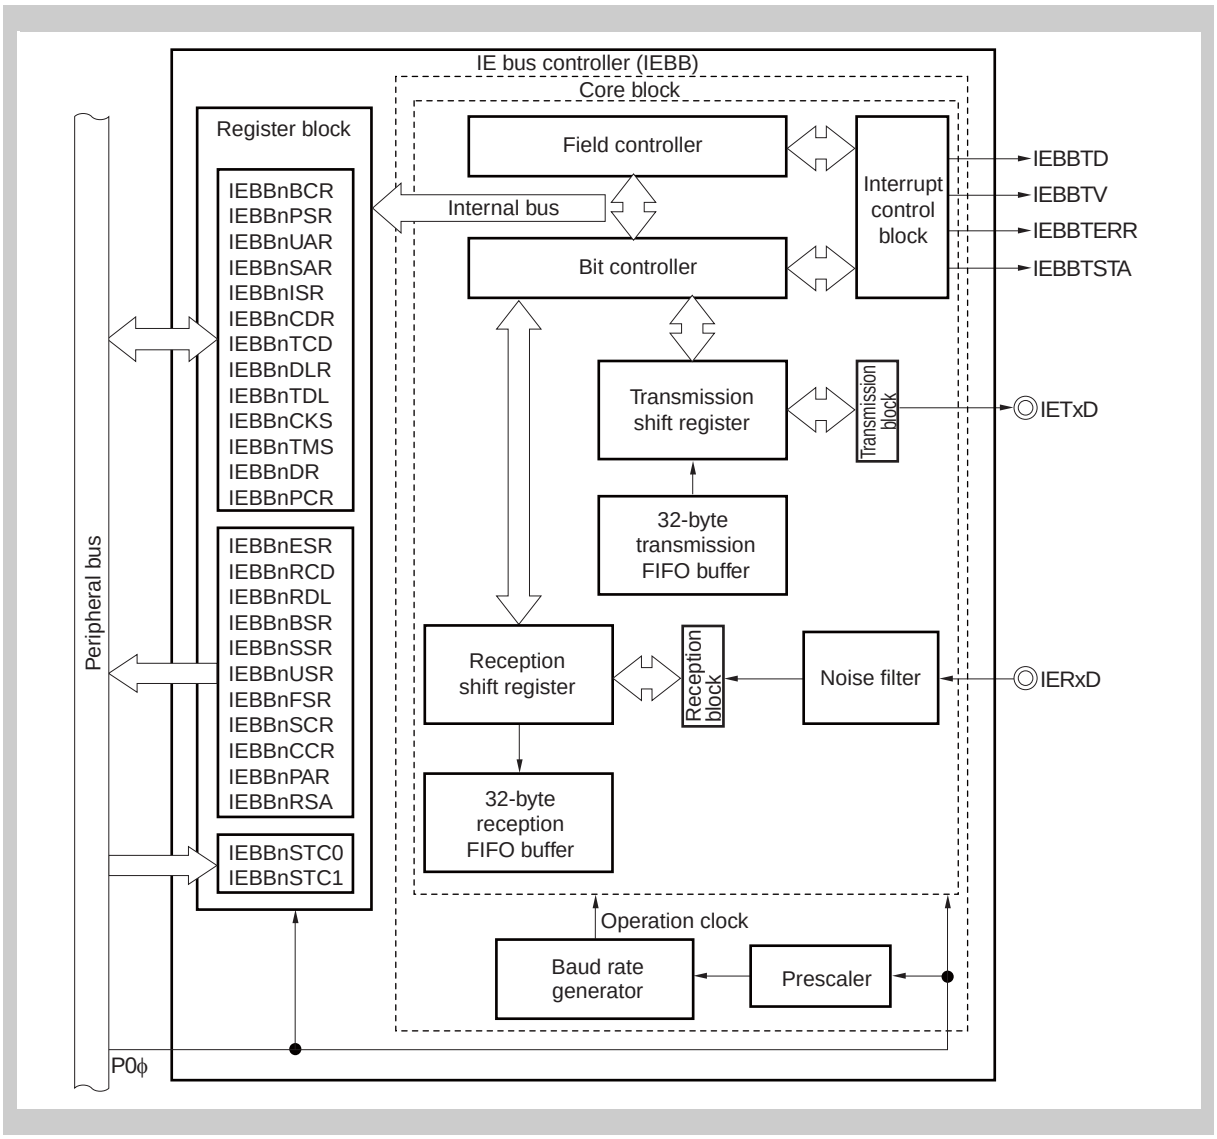

Figure 22-1 IEBBn block diagram

22.3 Registers

22.3.1 IEBBn register overview

The IEBBn is controlled by the following registers:

Table 22-6 IEBBn registers

Register name	Symbol	Address
IEBBn bus control register	IEBBnBCR	<IEBBn_base> + 0000_H
IEBBn power save register	IEBBnPSR	<IEBBn_base> + 0004_H
IEBBn unit address register	IEBBnUAR	<IEBBn_base> + 0008_H
IEBBn slave address register	IEBBnSAR	<IEBBn_base> + $000C_H$
IEBBn partner address register	IEBBnPAR	<IEBBn_base> + 0010_H
IEBBn reception slave address register	IEBBnRSA	<IEBBn_base> + 0014_H
IEBBn control data register	IEBBnCDR	<IEBBn_base> + 0018_H
IEBBn transmission control data register	IEBBnTCD	<IEBBn_base> + $001C_H$
IEBBn reception control data register	IEBBnRCD	<IEBBn_base> + 0020_H
IEBBn message length register	IEBBnDLR	<IEBBn_base> + 0024_H
IEBBn transmission message length register	IEBBnTDL	<IEBBn_base> + 0028_H
IEBBn reception message length register	IEBBnRDL	<IEBBn_base> + $002C_H$
IEBBn clock selection register	IEBBnCKS	<IEBBn_base> + 0030_H
IEBBn transfer mode setting register	IEBBnTMS	<IEBBn_base> + 0034_H
IEBBn pointer clear register	IEBBnPCR	<IEBBn_base> + 0038_H
IEBBn buffer status register	IEBBnBSR	<IEBBn_base> + $003C_H$
IEBBn slave status register	IEBBnSSR	<IEBBn_base> + 0040_H
IEBBn unit status register	IEBBnUSR	<IEBBn_base> + 0044_H
IEBBn interrupt status register	IEBBnISR	<IEBBn_base> + 0048_H
IEBBn error status register	IEBBnESR	<IEBBn_base> + $004C_H$
IEBBn field status register	IEBBnFSR	<IEBBn_base> + 0050_H
IEBBn success count register	IEBBnSCR	<IEBBn_base> + 0054_H
IEBBn communication count register	IEBBnCCR	<IEBBn_base> + 0058_H
IEBBn status clear register 0	IEBBnSTC0	<IEBBn_base> + $005C_H$
IEBBn status clear register 1	IEBBnSTC1	<IEBBn_base> + 0060_H
IEBBn data register	IEBBnDR	<IEBBn_base> + 0064_H

<IEBBn_base> The IEBBn base address <IEBBn_base> is defined in Table 22-2.

22.3.2 IEBBn control register details

(1) IEBBnBCR - IEBBn bus control register

The IEBBnBCR register is used to control the operation of IEBBn.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0000_H

Initial value 00_H

The IEBBnMSRQ, IEBBnALRQ, IEBBnSTXE, and IEBBnSRXE bits are reset by writing 0 to the IEBBnPW bit.

Cautions

1. When operation is enabled (when the IEBBnPW bit = 1), writing 1 to the IEBBnMSRQ bit is prohibited while the IEBBnMSRQ bit = 1. To write 1 to this bit, first clear it to 0.
2. Note the following when accessing the register:
   - When the IEBBnPW bit = 0, it is not possible to write to the IEBBnMSRQ, IEBBnALRQ, IEBBnSTXE, and IEBBnSRXE bits.
   - Because the IEBBnMSRQ, IEBBnALRQ, IEBBnSTXE, and IEBBnSRXE bits are reset at the same time by writing 0 to the IEBBnPW bit, even if an 8-bit write that results in the IEBBnPW bit being cleared to 0 is performed, the IEBBnMSRQ, IEBBnALRQ, IEBBnSTXE, and IEBBnSRXE bits are not written to. When an 8-bit write that results in the IEBBnPW bit being set to 1 is performed, the IEBBnMSRQ, IEBBnALRQ, IEBBnSTXE, and IEBBnSRXE bits can be written to.

     Example: If 78H is written to the IEBBnBCR register and then the register is read, 00H is returned.

     If F8H is written to the IEBBnBCR register and then the register is read, F8H is returned.

7	6	5	4	3	2	1	0
IEBBn PW	IEBBn MSRQ	IEBBn ALRQ	IEBBn STXE	IEBBn SRXE	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R

Table 22-7 IEBBnBCR register contents

Bit position	Bit name	Function
7	IEBBnPW	Communication enable flag 0: Stop IEBBn unit operation. 1: Enable IEBBn unit operation. Caution When the IEBBnPW bit is set (to 1), the IEBBnPSR, IEBBnUAR, IEBBnCKS, and IEBBnTMS registers below cannot be overwritten. Therefore, these registers must be set up before setting the IEBBnPW bit.
6	IEBBnMSRQ	Master request flag 0: Do not request the IEBBn unit as the master. 1: Request the IEBBn unit as the master.
5	IEBBnALRQ	Broadcast request flag 0: Request individual communication. 1: Request broadcast communication.
4	IEBBnSTXE	Slave transmission enable flag 0: Disable slave transmission. 1: Enable slave transmission.
3	IEBBnSRXE	Slave reception enable flag 0: Disable slave reception. 1: Enable slave reception.

(a) Communication enable flag (IEBBnPW): Bit 7

- Set/clear condition

  Set: By software (Write 1 to the IEBBnPW bit.)
  Clear: By software (Write 0 to the IEBBnPW bit.)

Depending on when the IEBBnPW bit is set (to 1), the IEBBn communication participation method differs.

Table 22-8 IEBBnPW bit setting timing and communication participation method

Timing for setting the IEBBnPW bit (to 1)	IEBBn communication participation method
When communication is not being performed on IEBus	Communication is participated in starting at the next frame or communication is started.
When communication is being performed on IEBus, and start bit communication is being performed by another bus master	Participates in communication from that frame if the start bit is detected. If the start bit is not detected, participates in communication from the next frame.
When communication is being performed on IEBus, and post-start bit communication is being performed by another bus master	Participates in communication from the next frame.

If the IEBBnPW bit is cleared (to 0), communication is immediately stopped even if it is in progress, and the internal flags and registers are reset, with some exceptions. The registers that are not reset by the IEBBnPW bit are shown below.

When the IEBBnPW = 0, even if another unit starts communication, IEBBn does not respond.

Table 22-9 Registers that are not reset by the IEBBnPW bit

Registers that are not reset by the IEBBnPW bit	Remark
IEBBnPSR	Not reset
IEBBnUAR	Not reset
IEBBnSAR	Not reset
IEBBnCDR	Data written from the CPU is not reset but data received during communication is.
IEBBnTCD	Not reset
IEBBnDLR	Data written from the CPU is not reset but data received during communication is.
IEBBnTDL	Not reset
IEBBnCKS	Not reset
IEBBnTMS	Not reset
IEBBnPCR	Not reset
IEBBnSTC0	Not reset
IEBBnSTC1	Not reset
IEBBnDR	Data written from the CPU is not reset but data received during communication is.

(b) Master request flag (IEBBnMSRQ): Bit 6

- Set/clear condition

  Set: By software

  Clear:

  – Single mode:

    The flag is cleared (to 0) by hardware when master communication is started and when the start interrupt of the master occurs.

    The flag is cleared (to 0) by hardware when a communication error interrupt occurs (when the IEBBnISR.IEBBnIEBE bit = 1).

    The flag is cleared (to 0) by hardware when arbitration loss occurs.

    The flag is cleared (to 0) when the IEBBnPW bit is cleared.

  – FIFO mode:

    The flag is cleared (to 0) by hardware after master communication starts, communication is performed without arbitration loss occurring, and the parity bit of the slave address field output by the unit is transmitted.

    The flag is cleared (to 0) by hardware when a communication error interrupt occurs (when the IEBBnISR.IEBBnIEBE bit = 1).

    The flag is cleared (to 0) by hardware if arbitration losses consecutively occur the number of times specified by the IEBBnTMS.IEBBnALC2 to IEBBnALC0 bits.

    The flag is cleared (to 0) when the IEBBnPW bit is cleared.

When the IEBBnMSRQ bit is set (to 1), the IEBus controller starts communication on IEBus as the master.

If communication is in progress on IEBus (if the start bit cannot be detected while the start bit is being communicated or if communication is in progress after the start bit has been detected), however, the controller waits until the current frame ends (holds the master request pending), outputs the start bit after the frame has ended, and starts communication as the master.

Cautions

1. Only set the IEBBnMSRQ bit after clearing the IEBBnSTXE bit to 0. After setting the IEBBnSTXE bit to 1, if arbitration loss occurs and the slave is selected, the transmission data prepared for the master might be used as slave transmission data.
2. Reissue master requests in the single mode and FIFO mode as described below.
   - Single mode:
     When arbitration is lost, use software to reissue master requests.
   - FIFO mode:
     When arbitration is lost, use hardware to reissue master requests.

     However, if arbitration losses consecutively occur the number of times specified by the IEBBnTMS.IEBBnALC2 to IEBBnALC0 bits, the request must be reissued by using software.

(c) Broadcast request flag (IEBBnALRQ): Bit 5

- Set/clear condition

  Set: By software

  Clear: By software

Cautions
1. The IEBBnMSRQ bit is cleared (to 0) by hardware, but the IEBBnALRQ bit is not. Therefore, if the next master request is for individual communication, clear the IEBBnALRQ bit (to 0).
2. Be sure to change the value of the IEBBnALRQ bit before setting the IEBBnMSRQ bit (to 1).

(d) Slave transmission enable flag (IEBBnSTXE): Bit 4

- Set/clear condition

  Set: By software

  Clear: By software

Slave transmission is controlled by the value of the slave transmission enable flag, but whether IEBBn performs slave transmission (whether there is an $\overline{\text{ACK}}$ signal response for the control field) is determined by other conditions.

The $\overline{\text{ACK}}$ signal response conditions for the control field are shown below.

Table 22-10 Control field $\overline{\text{ACK}}$ signal response conditions (when the received control data is 0H, 3H, 4H, 5H, 6H, or 7H)

Communication target (IEBBnUSR. IEBBnSRQF bit) Slave specification = 1 No specification = 0	Lock status (IEBBnUSR. IEBBnLCKF bit) Lock = 1 No lock = 0	Master unit judgment (IEBBnPAR register match) Lock request unit = 1 Other = 0	Slave transmission enabled (IEBBnBCR. IEBBnSTXE bit)	Slave reception enabled (IEBBnBCR. IEBBnSRXE bit)	Received Control Data					
					0H	3H	4H	5H	6H	7H
1	0	don't care	0	don't care	A	N	N	N	A	N
			1		A	A	N	N	A	A
	1	0	don't care		A	N	A	A	N	N
		1	0		A	N	A	A	A	N
			1		A	A	A	A	A	A
Other than the above					N					

Note A: Slave transmission is performed. (The $\overline{\text{ACK}}$ signal is returned.)
N: Slave transmission is not performed. (The NACK signal is returned.)

Slave transmission is not performed if the received control data is AH, BH, EH, or FH.

Table 22-11 Control field $\overline{\text{ACK}}$ signal response conditions (when the received control data is AH, BH, EH, or FH)

Communication target (IEBBnUSR. IEBBnSRQF bit) Slave specification = 1 No specification = 0	Lock status (IEBBnUSR. IEBBnLCKF bit) Lock = 1 No lock = 0	Master unit judgment (IEBBnPAR register match) Lock request unit = 1 Other = 0	Slave transmission enabled (IEBBnBCR. IEBBnSTXE bit)	Slave reception enabled (IEBBnBCR. IEBBnSRXE bit)	Received control data			
					AH	BH	EH	FH
1	0	don't care	don't care	1	A			
	1	1						
Other than the above					N			

Note A: The $\overline{\text{ACK}}$ signal is returned.
N: The NACK signal is returned.

Cautions
1. Set the IEBBnSTXE bit before the control field parity bit is received.
2. When there is a master request, clear the IEBBnSTXE bit (to 0) before setting the IEBBnMSRQ bit (to 1). This is to avoid transmission of the data of the IEBBnDR register that tries master transmission if the controller loses arbitration after master operation and if slave transmission is requested by the master.

(e) Slave reception enable flag (IEBBnSRXE): Bit 3

- Set/clear condition

  Set: By software

  Clear: By software

When the IEBBnSRXE bit = 1 and the reception control data for the communicated control field addressed to the unit is AH, BH, EH, or FH (or when the lock status is specified and the master unit address of the communication matches the address for which a lock was requested), the ACK signal is returned for the control field, and a slave reception operation is performed.

When the IEBBnSRXE bit = 0 and the reception control data for the communicated control field addressed to the unit is AH, BH, EH, or FH, the NACK signal is returned for the control field, and no slave reception operation is performed.

Cautions

1. Set the IEBBnSRXE bit before the control field parity bit is received.
2. The IEBBnSRXE bit is used to enable or disable slave reception for both individual and broadcast communication. For individual communication, a NACK signal can be returned for the control field to end communication by clearing the IEBBnSRXE bit to 0 (thereby prohibiting slave reception), but, for broadcast communication, although communication cannot be ended by clearing this bit because no ACK/NACK signal is transmitted, no data interrupt occurs because IEBBn does not respond to the broadcast communication.

(2) IEBBnPSR - IEBBn power save register

The IEBBnPSR register is used to operate and stop the IEBBn operation clock and to control the communication mode.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0004_H

Initial value 00_H

Cautions
1. The IEBBnPSR register can only be set up when the IEBBnBCR.IEBBnPW bit = 0. Do not set up the register when this bit = 1. If an attempt is made to set up the register when the IEBBnPW bit = 1, the value is ignored.
2. To use IEBBn, first set the IEBBnCLKE bit (to 1) and enable the operation clock.

   To start the bus operation, specify the settings below.

   • When communication has started

   1. Set up the IEBBnCKS register.
   2. Set the IEBBnCLKE bit (to 1). (The operation clock operates.)

      Set the IEBBnCMD bit to 0 or 1 to specify the communication mode.
   3. Set up registers such as IEBBnUAR, IEBBnSAR, IEBn0TCD, IEBBnTDL, and IEBBnDR depending on the type of communication.
   4. Set the IEBBnBCR.IEBBnPW bit (to 1) to start communication.

   • When communication is stopped

   1. Clear the IEBBnPW bit to 0.
   2. Clear the IEBBnCLKE bit (to 0). (The operation clock stops.)

7	6	5	4	3	2	1	0
IEBBn CLKE	IEBBn CMD	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R

Table 22-12 IEBBnPSR register contents

Bit position	Bit name	Function
7	IEBBnCLKE	Operation clock enable flag 0: Stop the operation clock. (This makes it possible to reduce the power consumed by IEBBn.) Initialize the prescaler and baud rate generator. 1: Enable the operation clock. The operation clock starts operating one clock cycle after the IEBBnCLKE bit is set (to 1). (For details, see Figure 22-2.) Similarly, the operation clock stops operating one clock cycle after the IEBBnCLKE bit is cleared (to 0). (For details, see Figure 22-2.)
6	IEBBnCMD	IEBBn communication mode setting flag 0: Specify communication mode 1. 1: Specify communication mode 2.

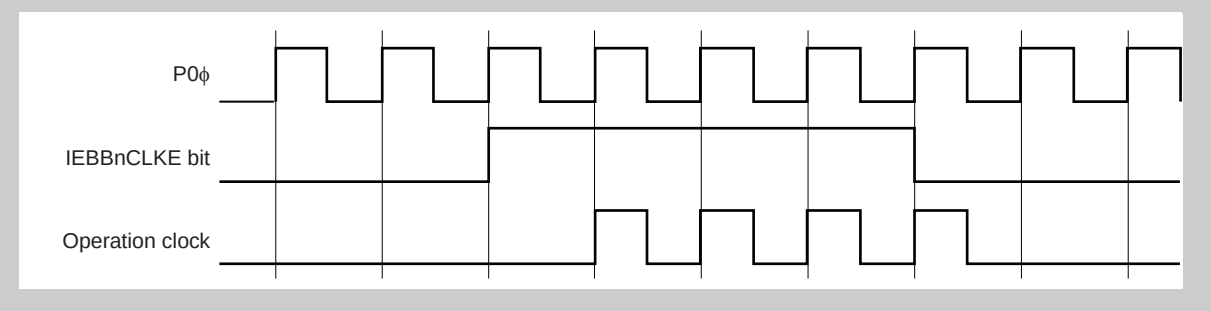

Figure 22-2 Starting and stopping the operation clock

(3) IEBBnUAR - IEBBn unit address register

The IEBBnUAR register is used to specify the unit address of the IEBus unit.

This register must always be set before starting communication.

Specify the unit address (12 bits) for bits 11 to 0.

Access This register can be read or written in 16-bit units.

Address <IEBBn_base> + 0008_H

Initial value 0000_H

Cautions
1. The IEBBnUAR register can only be set up when the IEBBnBCR.IEBBnPW bit = 0. Do not set up the register when this bit = 1. If an attempt is made to set up the register when the IEBBnPW bit = 1, the value is ignored.
2. Writing to this register in 8-bit units is prohibited.

15	14	13	12	11	10	9	8
0	0	0	0				
R	R	R	R	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(4) IEBBnSAR - IEBBn slave address register

The IEBBnSAR register is used to specify the address of the communication-partner slave unit during master communication.

During a master request, the value of this register is transmitted as the slave address field data.

Specify the slave address (12 bits) for bits 11 to 0.

Access This register can be read or written in 16-bit units.

Address <IEBBn_base> + $000C_H$

Initial value 0000_H

Cautions

1. When the IEBBnSAR register is overwritten during communication (while the IEBBnBCR.IEBBnPW bit = 1), communication might not be correctly performed. Therefore, overwriting is prohibited from when a master request is issued until the communication or frame completion timing.

   Note that overwriting is enabled at the following times:

   - When the IEBBnPW bit = 0
   - From when the IEBBnPW bit is set to 1 until the first master request (when the IEBBnMSRQ bit = 1)
   - From the communication or frame completion timing (assuming the IEBBnPW bit = 1 and the IEBBnMSRQ bit = 0) until the next master request (when the IEBBnMSRQ bit = 1)

2. Writing to this register in 8-bit units is prohibited.

15	14	13	12	11	10	9	8
0	0	0	0				
R	R	R	R	R/W	R/W	R/W	R/W
7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(5) IEBBnPAR - IEBBn partner address register

The IEBBnPAR register is used to store the reception master address in the master address field.

When operating the unit is enabled (when the IEBBnBCR.IEBBnPW bit = 1), the received master address is stored using the master address field regardless of whether the unit master is operating or the slave is operating.

- Storage in the single mode

  Upon completion of the parity period for the master address field, this is only performed if the parity value is normal and the unit is in the non-lock status.

- Storage in the FIFO mode

  If reading the data received during the previous communication has finished (if the IEBBnBSR.IEBBnRFLF bit = 0 and the IEBBnBSR.IEBBnSRFP4 to IEBBnSRFP0 bits = 00000), upon completion of the parity period for the master address field, storage is only performed if the parity value is normal and the unit is in the non-lock status. If reading the received data has not finished, the IEBBnPAR register is not updated until it finishes.

When there is a unit lock, because the address of the unit that requested the lock (the lock master) is retained, the IEBBnPAR register is not updated.

- Lock address transmission request reception in the single mode

  If a lock address transmission request is received from the master as a status transmission request, when the received control data receives the lock address (higher four bit) read request (5H), the value of the IEBBnPAR register is read by using software, and then the data in bits 15 to 8 of the IEBBnPAR register is written to the IEBBnDR register.
  In addition, if a lock address (lower 8 bits) read request (4H) is received, the value of the IEBBnPAR register is read by using software, and then the data in bits 7 to 0 of the IEBBnPAR register is written to the IEBBnDR register.

- Lock address transmission request reception in the FIFO mode

  If a lock address transmission request is received from the master as a status transmission request, the data in the IEBBnPAR register is automatically transmitted to the data field by using hardware.

Specify the partner address (12 bits) for bits 11 to 0.

Access This register is read-only, in 16-bit units.

Address <IEBBn_base> + 0010_H

Initial value 0000_H

This register is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

15	14	13	12	11	10	9	8
0	0	0	0				
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
R	R	R	R	R	R	R	R

(6) IEBBnRSA - IEBBn reception slave address register

The IEBBnRSA register is used to store the slave address value received using the slave address field.

When operating the unit is enabled (when the IEBBnBCR.IEBBnPW bit = 1), the received slave address is stored using the slave address field regardless of whether the unit master is operating or the slave is operating.

- Storage in the single mode

  This is performed upon the completion of the slave address field parity period if the parity value is normal.

- Storage in the FIFO mode

  If reading the data received during the previous communication has finished (if the IEBBnBSR.IEBBnRFLF bit = 0 and the IEBBnBSR.IEBBnSRFP4 to IEBBnSRFP0 bits = 00000), upon completion of the parity period for the slave address field, storage is only performed if the parity value is normal. Until reading the received data finishes, the IEBBnRSA register is not updated.

Specify the slave address (12 bits) for bits 11 to 0.

Access This register is read-only, in 16-bit units.

Address <IEBBn_base> + 0014_H

Initial value 0000_H

This register is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

15	14	13	12	11	10	9	8
0	0	0	0				
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
R	R	R	R	R	R	R	R

(7) IEBBnCDR - IEBBn control data register

The IEBBnCDR register is used to specify the control data transmitted using the control field.

After writing to the IEBBnCDR register, the IEBBnTCD register is written to.

After reading the IEBBnCDR register, the IEBBnRCD register value is read.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0018_H

Initial value 00_H

The read value is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

Caution When issuing a master request, be sure to set up the IEBBnCDR register before starting communication (when the IEBBnBCR.IEBBnMSRQ bit = 0).

Note The IEBBnCDR register consists of a write register and a read register. Therefore, data written to this register cannot be read as is. The data received during IEBus communication can be read.

7	6	5	4	3	2	1	0
0	0	0	0	IEBBn SLCD3	IEBBn SLCD2	IEBBn SLCD1	IEBBn SLCD0
R	R	R	R	R/W	R/W	R/W	R/W

(8) IEBBnTCD - IEBBn transmission control data register

The IEBBnTCD register is used to specify the control data transmitted using the control field.

The value of the lower 4 bits of the value written to the IEBBnTCD register is transmitted as control data by using the control field during master transmission.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + $001C_H$

Initial value 00_H

Cautions
1. When issuing a master request, be sure to set up the IEBBnTCD register before starting communication (when the IEBBnBCR.IEBBnMSRQ bit = 0).
2. Do not specify undefined values.
3. During broadcast transmission, specifying slave transmission control data is prohibited.

1	1	0	0	Undefined
1	1	0	1	Undefined
1	1	1	0	Write command
1	1	1	1	Write data

(9) IEBBnRCD - IEBBn reception control data register

The IEBBnRCD register is used to store the control data received using the control field.

The data received by using the control field is read to the lower 4 bits of the IEBBnRCD register. Data is stored in the IEBBnRCD register upon completion of the control field parity period if the parity value is normal.

- Storage in the single mode

  When a status transmission request is received, the user performs each process (settings for the transmission data of the IEBBnSSR register or the IEBBnPAR register) according to the value of the lower 4 bits of the IEBBnRCD register read value.

- Storage in the FIFO mode

  When a status transmission request is received, the hardware automatically performs the status transmission processing (settings for the transmission data of the IEBBnSSR register or the IEBBnPAR register).

Because it is necessary to judge whether the received data is a command or data, be sure to read the value of this register upon the completion of communication.

In the FIFO mode, if reading the data received during the previous communication has finished (if the IEBBnBSR.IEBBnRFLF bit = 0 and the IEBBnBSR.IEBBnSRFP4-SRFP0 bit = 00000), upon completion of the parity period for the control data field, storage is performed if the parity value is normal. Until reading the received data finishes, the IEBBnRCD register is not updated.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0020_H

Initial value 00_H

This register is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

1	1	0	1	Undefined
1	1	1	0	Write command
1	1	1	1	Write data

(10) IEBBnDLR - IEBBn message length register

The IEBBnDLR register is used to specify the message length data transmitted using the message length field.

After writing to the IEBBnDLR register, the IEBBnTDL register is written to.

After reading the IEBBnDLR register, the IEBBnRDL register value is read.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0024_H

Initial value 01_H

The read value is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

Caution When issuing a master request, be sure to set up the IEBBnDLR register before starting communication (when the IEBBnBCR.IEBBnMSRQ bit = 0).

Note The IEBBnDLR register consists of a write register and a read register. Therefore, data written to this register cannot be read as is. The data received during IEBus communication can be read.

7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(11) IEBBnTDL - IEBBn transmission message length register

The IEBBnTDL register is used to specify the message length data transmitted using the message length field.

The value written to the IEBBnTDL register is transmitted as message length data by using the message length field if the unit is the transmission unit (master transmission, slave transmission).

However, when a status transmission request is received, 0H is transmitted as the message length data regardless of the IEBBnTDL register setting.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0028_H

Initial value 01_H

Cautions
1. Be sure to set up the IEBBnTDL register before starting communication (when the IEBBnBCR.IEBBnMSRQ bit = 0).
2. The maximum number of bytes that can be transferred per frame is determined according to the communication mode. For example, when transferring 48 bytes in communication mode 1, perform communication by dividing the data among multiple frames. In this case, when performing the second communication, use the IEBBnSCR register to check the number of data bytes transmitted during the first communication, subtract the number of bytes that were successfully transmitted from the number of bytes you want to transmit, and then specify the result for the IEBBnTDL register. Write the next data to the IEBBnDR register at the same time, and then issue a master request.

7	6	5	4	3	2	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22-15 IEBBnTDL register contents

Bit								Setting	Number of remaining communication data bytes
7	6	5	4	3	2	1	0		
0	0	0	0	0	0	0	1	01H	1 byte
0	0	0	0	0	0	1	0	02H	2 bytes
...	...	...	...	...	...	...	...	...	...

...	...	...	...	...	...	...	...	...	...
1	1	1	1	1	1	1	1	FFH	255 bytes
0	0	0	0	0	0	0	0	00H	256 bytes

(12) IEBBnRDL - IEBBn reception message length register

The IEBBnRDL register is used to specify the message length data received using the message length field.

The IEBBnRDL register read value is the data received using the message length field.

- Storage in the single mode

  Storage proceeds if the parity value is normal at the end of the parity period for the message length field.

- Storage in the FIFO mode

  If reading the data received during the previous communication has finished (IEBBnBSR.IEBBnRFLF bit = 0 and the IEBBnBSR.IEBBnSRFP4-SRFP0 bit = 00000), upon completion of the parity period for the message length field, storage is performed if the parity value is normal. Until reading the received data finishes, the IEBBnRDL register is not updated.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + $002C_H$

Initial value 01_H

This register is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

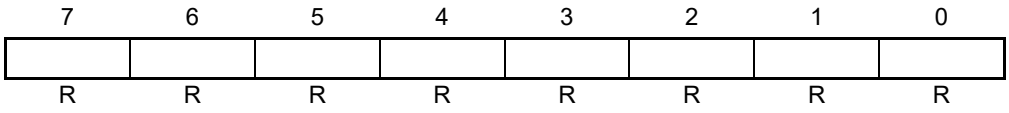

Table 22-16 IEBBnRDL register contents

Bit								Setting	Number of remaining communication data bytes
7	6	5	4	3	2	1	0		
0	0	0	0	0	0	0	1	01H	1 byte
0	0	0	0	0	0	1	0	02H	2 bytes
...	...	...	...	...	...	...	...	...	...
0	0	0	1	0	1	0	0	20H	32 bytes
...	...	...	...	...	...	...	...	...	...
1	1	1	1	1	1	1	1	FFH	255 bytes
0	0	0	0	0	0	0	0	00H	256 bytes

(13) IEBBnCKS - IEBBn clock selection register

The IEBBnCKS register is used to control the clock selection of the IEBus controller.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0030_H

Initial value 17_H

Caution The IEBBnCKS register can only be set up when the IEBBnBCR.IEBBnPW bit = 0 and the IEBBnPSR.IEBBnCLKE bit = 0. Do not set up the register when this bit = 1. If an attempt is made to set up the register when the IEBBnPW bit = 1, the value is ignored.

7	6	5	4	3	2	1	0
0	0	0	IEBBn PRS	0	IEBBn BRS2	IEBBn BRS1	IEBBn BRS0
R	R	R	R/W	R	R/W	R/W	R/W

Table 22-17 IEBBnCKS register contents

Bit position	Bit name	Function
4	IEBBnPRS	Specify the prescaler output (PRSOUT). 0: P0ϕ 1: P0ϕ2 Caution The conditions under which the prescaler is initialized are as follows: • When the IEBBnPRS bit is overwritten • When the IEBBnBCR.IEBBnPW bit = 0 and the IEBBnPSR.IEBBnCLKE bit = 1
2 to 0	IEBBnBRS [2-0]	Specify the operation clock output (MCK).

IEBBnBRS2	IEBBnBRS1	IEBBnBRS0	Operation clock output (MCK)
0	0	0	PRSOUT/1
0	0	1	PRSOUT/1
0	1	0	PRSOUT/2
0	1	1	PRSOUT/3
1	0	0	PRSOUT/4
1	0	1	PRSOUT/5
1	1	0	PRSOUT/6
1	1	1	PRSOUT/7

Caution The conditions under which the baud rate generator is initialized are as follows:
- When the IEBBnBRS2 to IEBBnBRS0 bits are overwritten
- When the IEBBnBCR.IEBBnPW bit = 0 and the IEBBnPSR.IEBBnCLKE bit = 1

Table 22-18 Input clock specification example

P0φ	IEBBnPRS	IEBBnBRS2	IEBBnBRS1	IEBBnBRS0	Specified value
32 MHz	0	1	0	0	04H

Caution The IEBus controller is designed to operate at 8 MHz.

(14) IEBBnTMS - IEBBn transfer mode setting register

The IEBBnTMS register is used to control the IEBus controller communication operations.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0034_H

Initial value 01_H

Caution The IEBBnTMS register can only be set up when the IEBBnBCR.IEBBnPW bit = 0. Do not set up the register when this bit = 1. If an attempt is made to set up the register when the IEBBnPW bit = 1, the value is ignored.

Table 22-19 IEBBnTMS register contents (1/2)

Bit position	Bit name	Function
7	IEBBnFMDE	Specify whether to enable or disable FIFO mode operation. 0: Disable FIFO mode operation (single mode). 1: Enable FIFO mode operation.
6, 5	IEBBnSLRI [1, 0]	Specify the IEBBTV occurrence timing during FIFO mode reception.

IEBBnSLRI1	IEBBnSLRI0	IEBBTV occurrence timing
0	0	When the reception data that has not been read from the reception FIFO buffer reaches 32 bytes
0	1	When the reception data that has not been read from the reception FIFO buffer reaches 24 bytes
1	0	When the reception data that has not been read from the reception FIFO buffer reaches 16 bytes
1	1	When the reception data that has not been read from the reception FIFO buffer reaches 8 bytes

Bit position	Bit name	Function
4, 3	IEBBnSLTI [1, 0]	Specify the IEBBTD occurrence timing during FIFO mode transmission.

IEBBnSLTI1	IEBBnSLTI0	IEBBTD occurrence timing
0	0	When the transmission FIFO buffer becomes empty
0	1	When the untransmitted data remaining in the transmission FIFO buffer reaches 2 bytes
1	0	When the untransmitted data remaining in the transmission FIFO buffer reaches 4 bytes
1	1	When the untransmitted data remaining in the transmission FIFO buffer reaches 8 bytes

Table 22-19 IEBBnTMS register contents (2/2)

<table>
<tr><th>Bit position</th><th>Bit name</th><th>Function</th></tr>
<tr><td>2 to 0</td><td>IEBBnALC
[2-0]</td><td>Specify the arbitration loss number.
This is only valid in the FIFO mode. The settings of these bits are invalid in the single mode.
When arbitration is lost and the counter is set to 0H, the IEBBnBCR.IEBBnMSRQ bit is not retained.
The settings of the IEBBnALC2 to IEBBnALC0 bits are always retained. The settings are not changed each time arbitration is lost.
The arbitration loss counter is decremented separately from the IEBBnALC2 to IEBBnALC0 bits.
Overwriting the IEBBnALC2 to IEBBnALC0 bits while the arbitration loss counter is counting does not affect the counter. (The values of the bits are specified for the arbitration loss counter when the IEBBnMSRQ bit = 1.)
<table>
<tr><th>IEBBnALC2</th><th>IEBBnALC1</th><th>IEBBnALC0</th><th>Maximum arbitration loss count</th></tr>
<tr><td>0</td><td>0</td><td>1</td><td>1</td></tr>
<tr><td>0</td><td>1</td><td>1</td><td>3</td></tr>
<tr><td colspan="3">Other than the above</td><td>Setting prohibited</td></tr>
</table>
</td></tr>
</table>

(a) FIFO operation enable bit (IEBBnFMDE): Bit 7

Differences between operation in the single mode and FIFO mode are shown below.

Table 22-20 Differences between operation in the single mode and FIFO mode

Transfer mode	Arbitration loss master request flag (IEBBnBCR.IEBBnMSRQ)	Arbitration loss error interrupt signal (IEBBTERR)	Support for slave status requests and lock address requests
Single mode	Clear	• The signal is not output. • The IEBBnESR.IEBBnABTE bit is fixed to 0.	During the slave status interrupt servicing, the value of the IEBBnSSR or IEBBnPAR register is written to the IEBBnDR register.
FIFO mode	The flag value is retained until arbitration is lost the number of times specified for the IEBBnALC2 to IEBBnALC0 bits. (The flag is cleared unless an error occurs during communication between third parties.)	• The signal is output if arbitration is lost the specified number of times. • The IEBBnESR.IEBBnABTE bit is simultaneously set (to 1).	The value of the IEBBnSSR or IEBBnPAR register is automatically sent by hardware by using the data field.

(b) FIFO mode reception IEBBTV occurrence timing specification bits (IEBBnSLRI1, IEBBnSLRI0): Bits 6, 5

In communication mode 1, the IEBBnSLRI1 and IEBBnSLRI0 bits are cleared to 00.

In communication mode 2, because data that exceeds 32 bytes is received, data must be read during reception. The occurrence timing of the data interrupt (IEBBTV) that requests that received data be read is specified by the IEBBnSLRI1 and IEBBnSLRI0 bits.

The IEBBTV interrupt occurs when received data is stored in the FIFO buffer and the number of unread bytes of data reaches the value specified for the IEBBnSLRI1 and IEBBnSLRI0 bits.

For the data no less than the number of bytes specified for the IEBBnSLRI1 and IEBBnSLRI0 bits, the data is read, and no interrupt occurs even if the number of unread bytes of received data exceeds the value specified for the IEBBnSLRI1 and IEBBnSLRI0 bits.

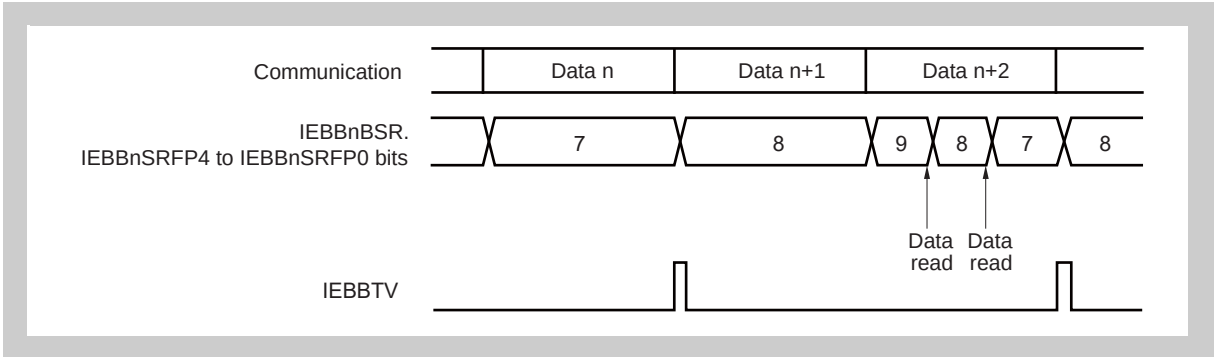

Figure 22-3 Example of operation in communication mode 2: When the IEBBnSLRI1 and IEBBnSLRI0 bits = 11

(c) FIFO mode transmission IEBBTB occurrence timing specification bits (IEBBnSLTI1, IEBBnSLTI0): Bits 4, 3

In communication mode 1, clear the IEBBnSLTI1 and IEBBnSLTI0 bits to 00.

In communication mode 2, because data that exceeds 32 bytes is transmitted, transmission data must be written during transmission. The occurrence timing of the data interrupt (IEBBTD) that requests that transmission data be written is specified by the IEBBnSLTI1 and IEBBnSLTI0 bits.

When less than 32 bytes of data are written to the FIFO buffer, IEBBTD occurs for the remaining number of bytes of data to be transmitted.

The IEBBTD interrupt occurs when transmission data is transferred from the FIFO buffer to the shift register and the number of bytes of data that have not been transmitted reaches the value specified for the IEBBnSLTI1 and IEBBnSLTI0 bits.

For data less than the number of bytes specified for the IEBBnSLTI1 and IEBBnSLTI0 bits, the data is written, and no interrupt occurs even if the number of bytes of data that have not been transmitted reaches the value specified for the IEBBnSLTI1 and IEBBnSLTI0 bits.

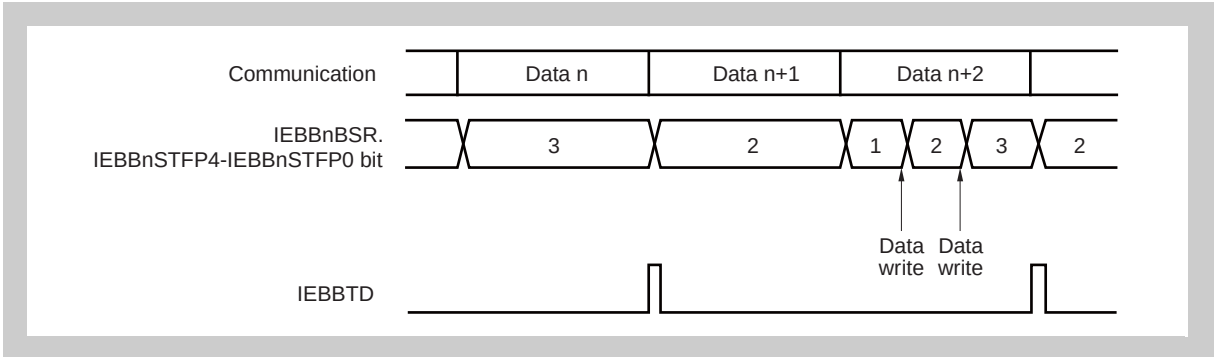

Figure 22-4 Example of operation in communication mode 2: When the IEBBnSLTI1 and IEBBnSLTI0 bits = 01

(d) Arbitration loss count specification bits (IEBBnALC2 to IEBBnALC0): Bits 2 to 0

This is only valid in the FIFO mode. The settings of these bits are invalid in the single mode.
When arbitration is lost and the counter is set to 0H, the IEBBnBCR.IEBBnMSRQ bit is not retained.

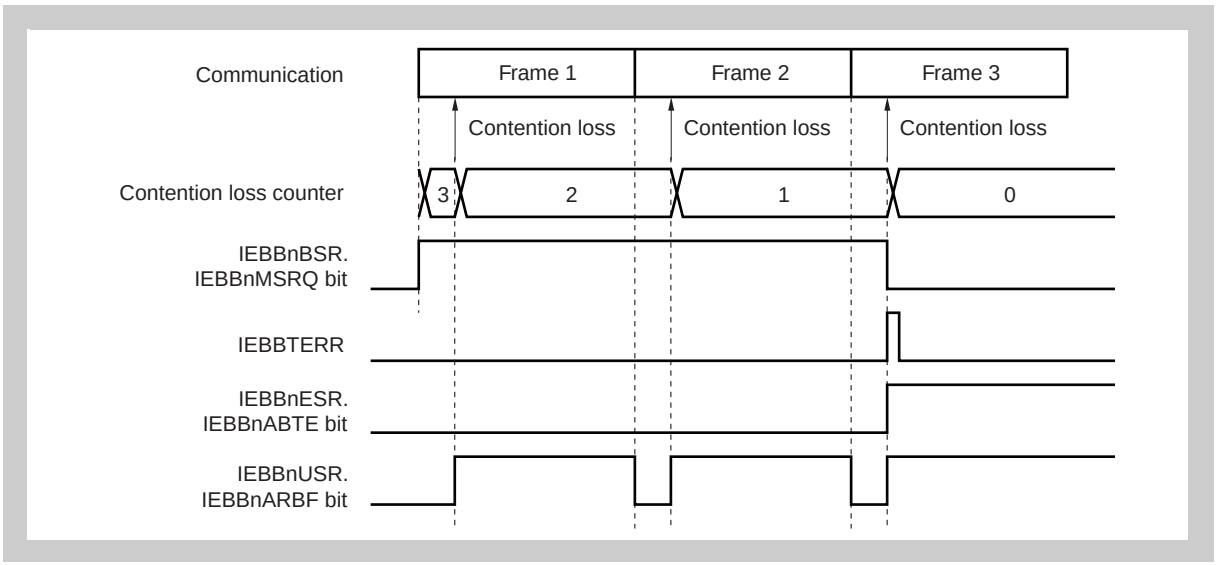

Figure 22-5 Example of operation in the FIFO mode: When the IEBBnALC2 to IEBBnALC0 bits = 011

(15) IEBBnPCR - IEBBn pointer clear register

The IEBBnPCR register is the trigger bit register for clearing the FIFO buffer pointer.

Access This register is write-only, in 8-bit units.

Address <IEBBn_base> + 0038_H

Initial value 00_H

7	6	5	4	3	2	1	0
IEBBn CRPT	IEBBn CTPT	0	0	0	0	0	0
W	W	R	R	R	R	R	R

Table 22-21 IEBBnPCR register contents

Bit position	Bit name	Function
7	IEBBnCRPT	Clear trigger bit for the store pointer and read pointer of the reception FIFO buffer 0: No operation 1: Clear the store pointer and read pointer of the reception FIFO buffer. The bit value can only be changed by setting the bit (to 1). Attempting to clear the bit (to 0) does not change the bit value. When the bit is read, 0 is always returned. Caution During reception or before reading received data, if the IEBBnCRPT bit is set to 1, the received data cannot be read. Except when discarding received data, only write 1 to the IEBBnCRPT bit after receiving and then reading data.
6	IEBBnCTPT	Clear the trigger bit for the write pointer and load pointer of the transmission FIFO buffer 0: No operation 1: Clear the write pointer and load pointer of the transmission FIFO buffer. The bit value can only be changed by setting the bit (to 1). Attempting to clear the bit (to 0) does not change the bit value. When the bit is read, 0 is always returned. Cautions 1. If the IEBBnCTPT bit = 1 while specifying data for the FIFO buffer or during transmission, the specified data cannot be transmitted. Except when discarding transmission data, only write 1 to the IEBBnCTPT bit after transmitting the data written to the FIFO buffer. 2. To discard transmission data, set the IEBBnCTPT bit to 1 during transmission. Because the data is lost in this case, transmission is not performed and an underrun error occurs.

(16) IEBBnBSR - IEBBn buffer status register

The IEBBnBSR register indicates the FIFO buffer status.

Access This register is read only, in 16-bit units.

Address <IEBBn_base> + $003C_H$

Initial value 0000_H

This register is reset when 0 is written to the IEBBnBCR.IEBBnPW bit.

15	14	13	12	11	10	9	8
IEBBn RFLF	IEBBn FOVR	0	IEBBn SRFP4	IEBBn SRFP3	IEBBn SRFP2	IEBBn SRFP1	IEBBn SRFP0
R	R	R	R	R	R	R	R
7	6	5	4	3	2	1	0
IEBBn TFLF	IEBBn FOVW	0	IEBBn STFP4	IEBBn STFP3	IEBBn STFP2	IEBBn STFP1	IEBBn STFP0
R	R	R	R	R	R	R	R

Table 22-22 IEBBnBSR register contents (1/2)

Bit position	Bit name	Function
15	IEBBnRFLF	Reception FIFO buffer full status flag 0: There are 31 bytes of data or less that have not been read in the reception FIFO buffer. 1: There are 32 bytes of data that have not been read in the reception FIFO buffer. This flag indicates that there are 32 bytes of data that have not been read in the reception FIFO buffer and that the buffer is full.
14	IEBBnFOVR	This flag indicates whether reception FIFO buffer over-reading has occurred. 0: Reception FIFO buffer over-reading has not occurred. 1: Reception FIFO buffer over-reading has occurred.
12 to 8	IEBBnSRFP [4-0]	This flag indicates the number of data bytes that have not been read remaining in the reception FIFO buffer. The (store pointer - read pointer) value can be read. However, the following values are used when IEBBnSRFP4 to IEBBnSRFP0 = 00000. • When the IEBBnRFLF bit = 0 and the IEBBnSRFP4 to IEBBnSRFP0 bits = 00000 Number of remaining data bytes that have not been read = 0 bytes • When the IEBBnRFLF bit = 1, and the IEBBnSRFP4 to IEBBnSRFP0 bits = 00000 Number of remaining data bytes that have not been read = 32 bytes
7	IEBBnTFLF	Transmission FIFO buffer full status flag 0: There are 31 bytes of data or less that have not been transferred in the transmission FIFO buffer. 1: There are 32 bytes of data that have not been transferred in the transmission FIFO buffer. This flag indicates that there are 32 bytes of data that have not been transferred in the transmission FIFO buffer and that the buffer is full.
6	IEBBnFOVW	Transmission FIFO buffer overwrite flag 0: No transmission FIFO buffer overwrite has occurred. 1: A transmission FIFO buffer overwrite has occurred.

Table 22-22 IEBBnBSR register contents (2/2)

Bit position	Bit name	Function
4 to 0	IEBBnSTFP [4-0]	This flag indicates the number of data bytes that have not been transferred remaining in the transmission FIFO buffer. The (write pointer - load pointer) value can be read. However, the following values are used when the IEBBnSTFP4 to STFPSTFP0 bits = 00000. • When the IEBBnTFLF bit = 0 and the IEBBnSTFP4 to IEBBnSTFP0 bits = 00000 Number of remaining data bytes that have not been transferred = 0 bytes • When the IEBBnTFLF bit = 1 and the IEBBnSTFP4 to IEBBnSTFP0 bits = 00000 Number of remaining data bytes that have not been transferred = 32 bytes

(a) Reception FIFO buffer over-read indicating flag (IEBBnFOVR): Bit 14

- Set/clear condition

  Set:

  – Single mode:

    The IEBBnFOVR bit is not set (to 1).

  – FIFO mode:

    When an over-read (a read of the IEBBnDR register while the store pointer = the read pointer) occurs for the reception FIFO buffer

  Clear:

  – Single mode or FIFO mode:

    By software (The flag is cleared when 1 is written to the IEBBnPCR.IEBBnCRPT bit.)

After reading the reception FIFO buffer, detect whether an over-read occurred by reading the IEBBnFOVR bit. (The data read during the over-read is the last bytes read during multiple operations.)

Even if an over-read is detected, because the data cannot be read again, perform software processing such as requesting retransmission. The IEBBnFOVR bit is cleared by writing 1 to the IEBBnPCR.IEBBnCRPT bit. (If an over-read occurred, the FIFO buffer pointers have already been cleared.)

(b) Transmission FIFO buffer overwrite flag (IEBBnFOVW): Bit 6

- Set/clear condition

  Set:

  – Single mode:

    The IEBBnFOVW bit is not set (to 1).

  – FIFO mode:

    When there are 32 bytes of that have not been transmitted in the transmission FIFO buffer and a 33rd byte of data is written

  Clear:

  – Single mode or FIFO mode:

    By software (The flag is cleared when 1 is written to the IEBBnPCR.IEBBnCTPT bit.)

After writing the required data to the transmission FIFO buffer, read the IEBBnFOVW bit before setting the master request flag. (IEBBnBCR.IEBBnMSRQ) (to 1) to detect whether an overwrite has occurred. If an overwrite is detected, clear the FIFO buffer pointers by writing 1 to the IEBBnPCR.IEBBnCTPT bit and then specify the data again.

(17) IEBBnSSR - IEBBn slave status register

The IEBBnSSR register indicates the communication status of the slave unit.

When a slave status transmission request interrupt is received form the master and the received control data is 0H or 6H, the IEBBnSSR register value is automatically written to the IEBBnDR register, and the slave status is transmitted.

In addition, when transmitting the slave status, because 01H is automatically transmitted as the message length, the IEBBnTDL register does not have to be set up.

Because bits 7 and 6 indicate the highest mode supported by the unit, they are fixed to 10 (which indicates communication mode 2).

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0040_H

Initial value 81_H

The IEBBnSSLF and IEBBnSTLF bits are reset by writing 0 to the IEBBnBCR.IEBBnPW bit.

The IEBBnSRXF and IEBBnSTXF bits are reset when the value of the IEBBnPW bit is overwritten with a different value.

7	6	5	4	3	2	1	0
1	0	0	IEBBn SSLF	0	IEBBn STLF	IEBBn SRXF	IEBBn STXF
R	R	R	R	R	R	R	R

Table 22-23 IEBBnSSR register contents (1/2)

Bit position	Bit name	Function
4	IEBBnSSLF	Slave transmission status flag 0: Slave transmission is stopped. 1: Slave transmission is enabled.
2	IEBBnSTLF	Lock status flag 0: Unlocked 1: Locked
1	IEBBnSRXF	IEBBnDR register or FIFO buffer reception status flag In the single mode 0: Received data has not been stored in the IEBBnDR register. 1: Received data has been stored in the IEBBnDR register. In the FIFO mode 0: Received data has not been stored in the FIFO buffer. 1: Received data has been stored in the FIFO buffer.

Table 22-23 IEBBnSSR register contents (2/2)

Bit position	Bit name	Function
0	IEBBnSTXF	IEBBnDR register or FIFO buffer transmission status flag • When communication is not being performed 1: The flag is always this value. • Master In the single mode (transmission) 0: The data specified for the IEBBnDR register has been transferred to the transmission shift register, and the next transmission data has not been written to the IEBBnDR register. 1: Transmission data remains in the IEBBnDR register. (This is the status up until the contents of the IEBBnDR register are transferred to the transmission shift register.) In the single mode (reception) 1: The flag is always this value. In the FIFO mode (transmission) 0: The number of bytes of data written to the FIFO buffer have been transferred from the FIFO buffer to the transmission shift register, and the next transfer data has not been written to the FIFO buffer. 1: This is the status from when communication starts until data is transferred to the transmission shift register and the number of bytes of data written to the FIFO buffer disappear. In the FIFO mode (reception) 1: The flag is always this value. • Slave In the single mode (transmission) 0: The data specified for the IEBBnDR register has been transferred to the transmission shift register, and the next transmission data has not been written to the IEBBnDR register. 1: This is the status from when communication starts until the first transmission data is transferred from the IEBBnDR register to the transmission shift register. This is also the status after writing data to the IEBBnDR register until the data is transferred to the transmission shift register. In the single mode (reception) 1: The flag is always this value. In the FIFO mode (transmission) 0: The number of bytes of data written to the FIFO buffer have been transferred from the FIFO buffer to the transmission shift register, and the next transfer data has not been written to the FIFO buffer. 1: This is the status from when communication starts until data is transferred to the transmission shift register and the number of bytes of data written to the FIFO buffer disappear. In the FIFO mode (reception) 1: The flag is always this value. • Third party 1: The flag is always this value.

(a) Slave transmission status flag (IEBBnSSLF): Bit 4

The value of the slave transmission enable flag (the IEBBnBCR.IEBBnSTXE bit) is applied as is.

(b) Lock status flag (IEBBnSTLF): Bit 2

The value of the lock status flag (the IEBBnUSR.IEBBnLCKF bit) is applied as is.

(c) IEBBnDR register or FIFO buffer reception status flag (IEBBnSRXF): Bit 1

- Set/clear condition

  Set:

  – Single mode:

    When received data is stored in the IEBBnDR register

  – FIFO mode:

    When received data is stored in the FIFO buffer

  Clear:

  – Single mode:

    When the IEBBnDR register contents are read

  – FIFO mode:

    When all the received data stored in the FIFO buffer has been read

In the single mode, when the IEBBnSRXF bit is set (to 1), the data interrupt IEBBTD occurs.

In the single mode, when IEBBTD occurs on data reception, the IEBBnDR register must be read before the next data is received. During broadcast communication, an overrun error occurs if the IEBBnDR register is not read regardless of whether IEBBTD has occurred. For details, see the description of the IEBBnOVRE bit in 22.3.2 (20) IEBBnESR - IEBBn error status register.

In the FIFO mode, even if the IEBBnSRXF bit is set (to 1), the interrupt signal IEBBTV is not generated. For details about the IEBBTV generation timing, see the description of the IEBBnSLRI1, IEBBnSLRI0 bits in 22.3.2 (14) IEBBnTMS - IEBBn transfer mode setting register.

(d) IEBBnDR register or FIFO buffer transmission status flag (IEBBnSTXF): Bit 0

- Set/clear condition

  Set:

  – When communication finishes

  – Single mode:

    When the IEBBnDR register is written to

  – FIFO mode:

    When transmission data is written to the FIFO buffer

  Clear:

  – Single mode:

    When the contents of the IEBBnDR register are written to the transmission shift register

  – FIFO mode:

    When the number of bytes of data written to the FIFO buffer are transferred from the FIFO buffer to the transmission shift register

In the single mode, when the IEBBnSTXF bit is cleared, the data interrupt IEBBTD occurs.

In the single mode, when IEBBTD occurs on data transmission, the next transmission data must be written to the IEBBnDR register.

Regardless of whether IEBBTD occurs, an underrun error occurs if IEBBnDR is not written to. For details, see the description of the IEBBnUNRE bit in 22.3.2 (20) IEBBnESR - IEBBn error status register.

In the FIFO mode, even if the IEBBnSRXF bit is set (to 1), the interrupt signal IEBBTD is not generated. For details about the IEBBTD generation timing, see the description of the IEBBnSLTI1, IEBBnSLTI0 bits in 22.3.2 (14) IEBBnTMS - IEBBn transfer mode setting register.

(18) IEBBnUSR - IEBBn unit status register

The IEBBnUSR register indicates the unit status.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0044_H

Initial value 00_H

This register is reset when the value of the IEBBnPW bit is overwritten with a different value.

7	6	5	4	3	2	1	0
0	IEBBn SRQF	IEBBn ARBF	IEBBn ALTF	IEBBn ACKF	IEBBn LCKF	0	0
R	R	R	R	R	R	R	R

Table 22-24 IEBBnUSR register contents

Bit position	Bit name	Function
6	IEBBnSRQF	Slave request flag for the unit 0: There are no slave requests. 1: There is a slave request.
5	IEBBnARBF	Arbitration result flag 0: Arbitration loss did not occur. 1: Arbitration loss occurred.
4	IEBBnALTF	Broadcast communication flag 0: Individual communication status 1: Broadcast communication status
3	IEBBnACKF	Acknowledge transmission flag 0: A $\overline{\text{NACK}}$ signal is transmitted. 1: An $\overline{\text{ACK}}$ signal is transmitted.
2	IEBBnLCKF	Lock status flag 0: Unlocked 1: Locked

(a) Slave request flag for the unit (IEBBnSRQF): Bit 6

- Set/clear condition

  Set:

  When the unit is requested as a slave (if the condition in Table 22-25 is satisfied), this flag is set (to 1) by hardware when the parity bit communication of the slave address field ends[a].

  Clear:

  This flag is cleared (to 0) by hardware when the unit is not requested as a slave (if the condition in Table 22-25 is not satisfied). The timing[a] is the same as that for setting the flag.

a) The bit is updated when the communication of the slave address field parity bit finishes without an error such as a parity error occurring. For example, if the slave address reception parity is incorrect, the IEBBnSRQF bit is not updated and the previous value is retained.

Table 22-25 Slave request conditions (conditions for setting the IEBBnSRQF bit)

Status of unit	Received master address	Communication mode	Received slave address
Not locked	don't care	Individual	IEBBnUAR match
		Broadcast	Group matching
			FFFH match
Locked	Locked master matching	Individual	IEBBnUAR match
		Broadcast	Group matching
			FFFH match

Note IEBBnUAR match: When the reception slave address and unit IEBBnUAR register match

Group match: When the reception-slave-address group address and unit IEBBnUAR-register group address match

FFFH match: When the reception slave address is FFFH

Table 22-26 $\overline{\text{ACK}}$ signal response condition for the slave address field

Status of unit	Received master address	Communication mode	Received slave address
don't care	don't care	Individual	IEBBnUAR match

Note IEBBnUAR match: When the reception slave address and unit IEBBnUAR register match

Caution If a unit other than the locked master communicates with the unit while the unit is locked, the IEBBnSRQF bit is not set but the $\overline{\text{ACK}}$ signal is returned to the slave address field. This is because communication must be continued, even for communication of a unit other than the locked master, if the control data received using the control field is a slave status transmission request.

(b) Arbitration result flag (IEBBnARBF): Bit 5

- Set/clear condition

  Set:

  When the data output by the unit does not match the received data during the arbitration period[a]

  Clear: After each communication frame start bit is transmitted or received

a) In the FIFO mode, the arbitration loss flag is set (to 1) based on the same condition even while the master request flag (IEBBnBCR.IEBBnMSRQ) is retained.

Note that, if arbitration is lost in the FIFO mode, a NACK reception error is detected by returning the NACK signal after control data reception, and software processing by outputting IEBBTERR is required.

In the case of a status transmission request, the NACK signal is not returned because there is an automatic response.

The IEBBnARBF bit is set (to 1) if there is inter-unit-data contention during the arbitration period (the broadcast field and master address field period) and the unit loses arbitration.

Arbitration loss is judged to have occurred when the unit output data does not match the received data.

Because the IEBus controller uses AND logic, the unit that outputs 0 wins arbitration.

In other words, among units that output broadcast data (0) for the broadcast field, the unit that has the smallest master address wins arbitration.

Caution In the single mode, when the start interrupt occurs upon issuing a master request, use the IEBBnARBF bit to check for arbitration loss. To transfer data again in the case of arbitration loss, perform software processing to issue another master request.

In the FIFO mode, another master request is issued even if arbitration is lost the number of times specified by the IEBBnTMS.IEBBnALC0 to IEBBnALC2 bits. If the number of arbitration losses exceeds this setting, an interrupt occurs to indicate an arbitration loss error. To transfer data again, perform software processing to issue another master request.

(c) Broadcast communication flag (IEBBnALTF): Bit 4

Flag indicating whether the unit is performing broadcast communication. The contents of the flag are updated in the broadcast field of each frame.

- Set/clear condition

  Set: When “broadcast” is received by the broadcast field

  Clear: When individual is received by the broadcast field

Caution The broadcast flag is updated regardless of whether IEBus is the communication target.

In the FIFO mode, storage is performed upon header completion if reading the data received during the previous communication has finished (if the IEBBnBSR.IEBBnRFLF bit = 0 and the nBSR.IEBBnSRFP4 to IEBBnSRFP0 bits = 00000). Until reading the received data finishes, the IEBBnALTF register is not updated.

(d) Acknowledge transmission flag (IEBBnACKF): Bit 3

This flag indicates whether the $\overline{\text{ACK}}$ signal was transmitted during the acknowledge bit period of the acknowledge bit field when IEBus is the receiving unit.

- Set/clear condition

  Set:

  When $\overline{\text{ACK}}$ is transmitted upon the completion of the acknowledge bit period for each field

  Clear:

  When NACK is transmitted upon the completion of the acknowledge bit period for each field

Cautions
1. If a communication error occurs and the unit returns to the initial status, no update is performed at the end of the acknowledge bit period for the corresponding field. For example, if the reception parity for the control field is incorrect, because IEBBn changes to the initial status (the communication standby status) after parity reception due to the parity error, a NACK signal is returned by using the control field (more accurately, no $\overline{\text{ACK}}$ signal is returned), but this is not applied to the IEBBnACKF bit, and the previous value is retained.
2. In the single mode, because the occurrence timing (when IEBBTSTA or IEBBTV becomes active) for the start interrupt and status transmission interrupt is when parity bit reception ends, the reading of the IEBBnUSR register by the previously described interrupt in the slave mode during interrupt handler processing might overlap with the changing of the IEBBnACKF bit.

(e) Lock status flag (IEBBnLCKF): Bit 2

A flag that indicates whether the unit is locked.

- Set/clear condition

  Set:

  When an individual communication frame ends, lock-related data (3H, 6H, AH, and BH) is received by using the control field, the communication completion flag (the IEBBnISR.IEBBnETRF bit) is cleared (to 0), and the frame completion flag (the IEBBnISR.IEBBnEFMF bit) is set (to 1).

  Clear:

  When an individual communication frame ends, lock-related data (3H, 6H, AH, and BH) is received by using the control field, and the communication completion flag (the IEBBnISR.IEBBnETRF bit) is set (to 1)

Cautions

1. Locking and unlocking are performed only during individual communication, not during broadcast communication.
2. While the master is locked, communication from a unit other than the master is not generally acknowledged. However, as an exception, if the control data (0H, 4H, or 5H) of a slave status transmission request is received, the communication is acknowledged even if it is not from the locked master. Note that, at this time, only a status request interrupt occurs, not a start interrupt or completion interrupt.

(19) IEBBnISR - IEBBn interrupt status register

The IEBBnISR status register indicates the interrupt source when an IEBBTSTA, IEBBTERR, or IEBBTV interrupt occurs.

Each time the IEBBTSTA, IEBBTERR, and IEBBTV interrupts occur, the IEBBnISR register is read, and the specified interrupt servicing is performed.

Access Only bit 6 can be read or written in 8-bit units.

Bits other than bit 6 are read-only, in 8-bit units.

Address <IEBBn_base> + 0048_H

Initial value 00_H

The IEBBnIEBE bit is reset when 0 is written to the IEBBnBCR.IEBBnPW bit.

Bits other than IEBBnIEBE are reset when the value of the IEBBnPW bit is overwritten with a different value.

Caution Be sure to set bits 1, and 7 to 0.

7	6	5	4	3	2	1	0
0	IEBBn IEBE	IEBBn STRF	IEBBn STSF	IEBBn ETRF	IEBBn EFMF	0	IEBBn FOVE
R	R/W[a]	R	R	R	R	R	R

a) Only the IEBBnIEBE bit can be written. Note that, when writing to the IEBBnIEBE bit, the bit can only be cleared (to 0). Even if 1 is written, the IEBBnIEBE bit is not set (to 1).

Table 22-27 IEBBnISR register contents

Bit position	Bit name	Function
6	IEBBnIEBE	Communication error flag 0: No communication error has occurred. 1: A communication error has occurred.
5	IEBBnSTRF	Start interrupt flag 0: No start interrupt has occurred. 1: A start interrupt has occurred.
4	IEBBnSTSF	Status transmission flag (slave) 0: There is no status transmission request. 1: There is a status transmission request.
3	IEBBnETRF	Communication completion flag 0: Communication of the number of transmission bytes specified by the message length field has not finished. 1: Communication of the number of transmission bytes specified by the message length field has finished.
2	IEBBnEFMF	Frame completion flag 0: The frame (communication of the maximum number of transmission bytes[a]) has not finished. 1: The frame (communication of the maximum number of transmission bytes[a]) has finished.
0	IEBBnFOVE	Frame over error flag 0: No frame over error has occurred. 1: A frame over error has occurred.

a) Communication mode 1: 32 bits, communication mode 2: 128 bits

(a) Communication error flag (IEBBnIEBE): Bit 6

A flag that indicates a communication error has occurred.

- Set/clear condition

  Set:

  – Single mode:

    When a timing error, parity error (except in the data field during individual reception), NACK reception error, underrun error, or overrun error (during broadcast reception) occurs

  – FIFO mode:

    When a timing error, parity error (except in the data field during individual reception), NACK reception error, underrun error, overrun error (during broadcast reception), or arbitration loss error occurs

  Clear:

  – Single mode or FIFO mode:

    By software (The flag is cleared (to 0) when 0 is written to the IEBBnIEBE bit.)

When a communication error occurs, IEBBTERR IEBBTV occur in the single mode, and IEBBTERR occurs in the FIFO mode.

It is possible to determine what caused the error by reading the IEBBnESR and IEBBnISR registers.

(b) Start interrupt flag: (IEBBnSTRF): Bit 5

A flag that indicates the start interrupt.

- Set/clear condition

  Set:

  – Single mode:

    The flag is set (to 1) during master unit operation, regardless of whether arbitration is won or lost.

    The flag is set (to 1) during slave unit operation if there is a slave request (when the IEBBnUSR.IEBBnSRQF bit = 1) from the master (only the locked master when the unit is locked).

    The flag is set upon the completion of the slave address field parity period in all cases.

  – FIFO mode: The IEBBnSTRF bit is not set (to 1).

  Clear:

  – Single mode:

    If the unit is the communication target (during communication with the master unit or slave unit), the flag is cleared (to 0) by hardware when a status transmission interrupt, communication completion interrupt, frame completion interrupt, transmission data write request interrupt, reception data read interrupt, or communication error interrupt occurs.

  – FIFO mode: The IEBBnSTRF bit is normally cleared.

In the single mode, IEBBTSTA and IEBBTV occur when a start interrupt occurs. In the FIFO mode, the start interrupt, IEBBTSTA, and IEBBTV do not occur.

Cautions
1. When a start interrupt occurs, read the IEBBnUSR register to check the slave request flag (IEBBnSRQF) and arbitration result flag (IEBBnARBF) for the unit.
2. If the arbitration result flag (IEBBnARBF) is set (to 1) when a start interrupt occurs after the unit issues a master request, perform software processing to reissue the master request.

(c) Status transmission flag (slave) (IEBBnSTSF): Bit 4

This flag indicates that the master requested transmission of the slave status and lock address (higher 4 bits and lower 8 bits) when the controller was serving as a slave.

- Set/clear condition

  Set:

  – Single mode:

  When the unit is not locked, there is a slave request from any master, and 0H or 6H is received by using the control field

  When the unit is locked, there is a slave request from the locked master, and 0H, 4H, 5H, or 6H is received by using the control field, or when 0H, 4H, or 5H is received from a unit other than the locked master by using the control field

  The flag is set upon the completion of the control field parity period in all cases.

  For details, see Table 22-28.

  – FIFO mode: The IEBBnSTSF bit is not set (to 1).

  Clear:

  – Single mode:

  If the unit is the communication target (during communication with the master unit or slave unit), the flag is cleared (to 0) by hardware when a start interrupt, communication completion interrupt, frame completion interrupt, transmission data write request interrupt, reception data read interrupt, or communication error interrupt occurs.

  – FIFO mode: The IEBBnSTSF bit is normally cleared.

In the single mode, IEBBTSTA and IEBBTV occur when there is a status transmission request. In the FIFO mode, no interrupt signal is generated even if there is a status transmission request.

Caution Even if the slave transmission enable flag (the IEBBnBCR.IEBBnSTXE bit) is set to the prohibited value (0), the IEBBnSTSF bit is set (to 1).

Table 22-28 Conditions for setting the status transmission request flag (slave)

Various statuses					Value received using the control field				
equa	lockf	eqpa	IEBBn STXE	IEBBn SRXE	0H	3H, 7H	4H, 5H	6H	AH, BH, EH, FH
1	0	0	Any	Any	Set	Not set	Not set	Set	Not set
1	0	1	Any	Any	Set	Not set	Not set	Set	Not set
1	1	0	Any	Any	Set	Not set	Set	Not set	Not set
1	1	1	Any	Any	Set	Not set	Set	Set	Not set

Note equa: Unit match (during individual communication, IEBBnUAR register match

lockf: Whether there is a lock

eqpa: Lock master match

IEBBnSTXE: Slave transmission enable flag (IEBBnBCR register bit 4)

IEBBnSRXE: Slave reception enable flag (IEBBnBCR register bit 3)

If a slave status transmission request interrupt occurs in the single mode, read the IEBBnCDR register to check the received control data contents, and then write the required slave status information to the IEBBnDR register.

The received control data and data written to the IEBBnDR register are shown below.

Table 22-29 Received control data and data written to the IEBBnDR register

Received control data	Function	Data written to the IEBBnDR register
0H, 6H	Slave status transmission	Value read from the IEBBnSSR register
4H	Transmission of the lower 8 bits of the lock address	Lower 8 bits of the IEBBnPAR register
5H	Transmission of the higher 4 bits of the lock address	Higher 8 bits of the IEBBnPAR register

Caution After a slave status transmission request interrupt occurs, be sure to write the appropriate data to the IEBBnDR register before the completion of the message length field.

(d) Communication completion flag (IEBBnETRF): Bit 3

A flag that indicates whether communication ends after the number of bytes set in the message length field have been transferred.

- Set/clear condition

  Set:

  – Single mode:

    When the unit is the communication target (during communication with the master unit or slave unit) and the value of the IEBBnSCR register becomes 0 at the end of the data field acknowledge period

  Clear:

  – Single mode:

    The flag is cleared (to 0) by hardware when a start interrupt, status transmission interrupt, frame completion interrupt (when a communication completion interrupt does not occur), transmission data write request interrupt, reception data read interrupt, or communication error interrupt occurs.

In the single mode, IEBBTSTA and IEBBTV occur when the communication completion flag is set (to 1).

In the FIFO mode, the IEBBTSTA interrupt occurs at the same timing as in the single mode.

In the FIFO mode, reading the IEBBnETRF bit is prohibited. If the bit is read, the returned value is undefined.

In the FIFO mode, after IEBBTSTA occurs, transmission and reception can be controlled by performing the software processing below.

- When reception ends

1. Detecting the completion of communication based on the occurrence of the IEBBTSTA interrupt
2. Checking whether communication or a frame has finished by using the IEBBnFSR.IEBBnRTRF bit
3. Checking the number of received data bytes by using the IEBBnBSR.IEBBnSRFP4 to IEBBnSRFP0 bits (the number of bytes that have not been read)
4. Reading the received data from the IEBBnDR register (the reception FIFO buffer)

- When transmission ends

1. Detecting the completion of communication based on the occurrence of the IEBBTSTA interrupt
2. Checking whether communication or a frame has finished by using the IEBBnFSR.IEBBnTTRF bit
3. Checking the number of transmission data bytes by using the IEBBnBSR.IEBBnSTFP4 to IEBBnSTFP0 bits (the number of bytes that have not been transmitted)
4. Proceeding to retransmission processing if there is data that has not been transmitted

(e) Frame completion flag (IEBBnEFMF): Bit 2

This flag indicates whether communication ends after the maximum number of bytes (communication mode 1: 32 bytes, communication mode 2: 128 bytes) have been transferred.

- Set/clear condition

  Set:

  – Single mode:

    When the unit is the communication target (during communication with the master unit or slave unit) and the value of the IEBBnCCR register becomes 0 at the end of the data field acknowledge period

  Clear:

  – Single mode:

    The flag is cleared (to 0) by hardware when a start interrupt, status transmission interrupt, communication completion interrupt (when a frame completion interrupt does not occur), transmission data write request interrupt, reception data read interrupt, or communication error interrupt occurs.

In the single mode, IEBBTSTA and IEBBTV occur when the frame completion flag is set (to 1).

Cautions
1. In the single mode, if the IEBBnSCR and IEBBnCCR registers are both cleared to 00H at the end of the data field acknowledge period, the IEBBnETRF and IEBBnEFMF bits are set (to 1) at the same time.
2. In the single mode, if the last data field is a NACK signal when the maximum number of bytes that can be transmitted is reached during retransmission, the IEBBnEFMF and IEBBnIEBE bits (NACK reception error) are set (to 1) at the same time.

In the FIFO mode, the IEBBTSTA interrupt occurs at the same timing as in the single mode.

In the FIFO mode, reading the IEBBnEFMF bit is prohibited. If the bit is read, the returned value is undefined.

After IEBBTSTA occurs, transmission and reception can be controlled by performing the software processing below.

- When reception ends

1. Detecting the completion of communication based on the occurrence of the IEBBTSTA interrupt
2. Checking whether communication or a frame has finished by using the IEBBnFSR.IEBBnRTRF bit
3. Checking the number of received data bytes by using the IEBBnBSR.IEBBnSRFP4 to IEBBnSRFP0 bits (the number of bytes that have not been read)
4. Reading the received data from the IEBBnDR register (the reception FIFO buffer)

- When transmission ends

1. Detecting the completion of communication based on the occurrence of the IEBBTSTA interrupt
2. Checking whether communication or a frame has finished by using the IEBBnFSR.IEBBnTTRF bit
3. Checking the number of transmission data bytes by using the IEBBnBSR.IEBBnSTFP4 to IEBBnSTFP0 bits (the number of bytes that have not been transmitted)
4. Proceeding to retransmission processing if there is data that has not been transmitted

(f) Frame over error flag (IEBBnFOVE): Bit 0

This flag indicates that a frame over error has occurred.

- Set/clear condition

  Set:

  – Single mode: The IEBBnFOVE bit is not set (to 1).

  – FIFO mode:

    If the next broadcast communication is received as a slave unit before reading the data received during the previous communication finishes, the flag is set (to 1) after the first data field parity period finishes.

  Clear:

  – Single mode or FIFO mode:

    By software

    (The flag is cleared (to 0) when 1 is written to the IEBBnSTC1.IEBBnCLFF bit.)

In the single mode, the IEBBnFOVE bit is not set (to 1), and no interrupt requests occur.

In the FIFO mode, IEBBTERR occurs when the IEBBnFOVE bit is set (to 1).

Even if a frame over error occurs for the current frame, the data received during the previous frame is valid.

(20) IEBBnESR - IEBBn error status register

The IEBBnESR register is used to indicate the cause when an IEBus controller communication error interrupt occurs. Each bit of the IEBBnESR register is set (to 1) as soon as the communication error flag of the IEBBnISR register (IEBBnIEBE) is set (to 1). The cause of a communication error, if any, can be identified by checking the contents of the IEBBnESR register. (If the IEBBnISR.IEBBnIEBE bit is already set to 1, only the bits of the IEBBnESR register are set (to 1).)

Note that the bits can only be set (to 1) by hardware and are cleared by writing 1 to the IEBBnSTC0 register.

When 1 is written to the IEBBnSTC0 register, if there is contention with the hardware trying to specify (1), the hardware is prioritized.

Note that writing to the IEBBnESR register is invalid.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + $004C_H$

Initial value 00_H

This register is reset when the value of the IEBBnBCR.IEBBnPW bit is overwritten with a different value.

Caution When a communication error occurs, IEBBn returns to the initial status and prepares for the next communication. Regardless of whether an error occurs, if the next communication is started without handling errors, any error flags that have been set remain set. (If the system returns to the initial status due to a timing error, and a parity error is received during the next communication, both the timing error and parity error bits of the IEBBnESR register are set to 1.)
Therefore, handle any errors that occur before the next communication starts.

Table 22-30 IEBBnESR register contents (1/2)

Bit position	Bit name	Function
7	IEBBnTIME	Timing error occurrence flag 0: No timing error has occurred. 1: A timing error has occurred.
6	IEBBnPARE	Parity error occurrence flag 0: No parity error has occurred. 1: A parity error has occurred.
5	IEBBnNACE	NACK reception error flag 0: No NACK reception error has occurred. 1: A NACK reception error has occurred.
4	IEBBnUNRE	Underrun error occurrence flag 0: No underrun error has occurred. 1: An underrun error has occurred.

Table 22-30 IEBBnESR register contents (2/2)

Bit position	Bit name	Function
3	IEBBnOVRE	Overrun error occurrence flag 0: No overrun error has occurred. 1: An overrun error has occurred.
1	IEBBnABTE	Arbitration loss error occurrence flag 0: The number of arbitration losses specified for the arbitration loss count setting bits (IEBBnTMS.IEBBnALC2 to IEBBnALC0) have not occurred. 1: The number of arbitration losses specified for the arbitration loss count setting bits (IEBBnTMS.IEBBnALC2 to IEBBnALC0) have occurred.
0	IEBBnTRDE	Inter-third-party communication error occurrence flag 0: An error occurred during communication targeting the unit. 1: An error occurred during inter-third-party communication.

(a) Timing error occurrence flag (IEBBnTIME): Bit 7

- Set condition

  Set: This flag is set (to 1) if a timing error occurs.

A timing error occurs if the high-/low-level width of the communication bit is not the defined value.

The defined value of the high- and low-level width is set to the bit processing block and monitored by the internal timer.

(b) Parity error occurrence flag (IEBBnPARE): Bit 6

- Set condition

  Set: This flag is set (to 1) if a parity error occurs.

When the unit is the reception unit (including while communication between others is being monitored), a parity error occurs when the parity data generated by the data received using the master address field, slave address field, control data field, or message length field does not match the received parity data.

However, when there is a data field mismatch, a NACK signal is returned and a data retransmission request is issued during individual communication, but a parity error occurs during broadcast communication.

Note During the above parity period, if the parity data received on the transmission side is inverted for some reason, a timing error occurs and communication ends.

Table 22-31 Operation when the parity data does not match

Field	Communication mode	Operation when the parity data does not match
Master address field	Individual/broadcast	A parity error occurs.
Slave address field	Individual/broadcast	A parity error occurs.
Control data field	Individual/broadcast	A parity error occurs.
Message length field	Individual/broadcast	A parity error occurs.
Data field	Individual	A NACK signal is returned to request retransmission.
	Broadcast	A parity error occurs.

(c) NACK reception error flag (IEBBnNACE): Bit 5

- Set condition

  Set: This flag is set (to 1) if a NACK reception error occurs.

A NACK reception error occurs if a NACK signal is received during the acknowledge bit period of the slave address field, control data field, or message length field during individual communication, regardless of whether the controller is operating as the master or slave.

When a NACK signal is received for the data field, no NACK reception error generally occurs because this reception signals a data retransmission request. However, if the last data field is a NACK signal, a NACK reception error does occur.

During reception, a NACK reception error is judged to have occurred if an output NACK signal is received for the last data of the slave address field, control data field, message length field, or data field.

Note that, during broadcast communication, no NACK reception errors occur because ACK/NACK signal judgment is not performed.

No NACK reception errors occur during inter-third-party communication because only timing/parity errors are detected as errors. However, for the slave address field, NACK reception error judgment is performed because communication is participated in as a slave.

Table 22-32 NACK reception error judgment period

Communication mode		Slave address field	Control data field Data field	Message length field	Data field (last)
Individual communication	Master transmission	Occurs	Occurs	Occurs	Occurs
	Master reception	—	—	Occurs	Occurs
	Slave transmission	—	—	Occurs	Occurs
	Slave reception	Occurs	Occurs	Occurs	Occurs
	Inter-third-party communication	Occurs	Does not occur	Does not occur	Does not occur
Broadcast communication	All	Does not occur	Does not occur	Does not occur	Does not occur

(d) Underrun error occurrence flag (IEBBnUNRE): Bit 4

- Set condition

  Set:

  – Single mode:

  During data transmission using the data field, an underrun error occurs if writing the next data to be transmitted to the IEBBnDR register does not finish before the end of the data-field acknowledge bit period following the occurrence of IEBBTD, and this flag is set (to 1). However, if the NACK signal is received during the acknowledge bit period, no underrun error occurs because retransmission is performed.

  During inter-third-party communication, underrun errors do not occur because only timing/parity errors are detected as errors.

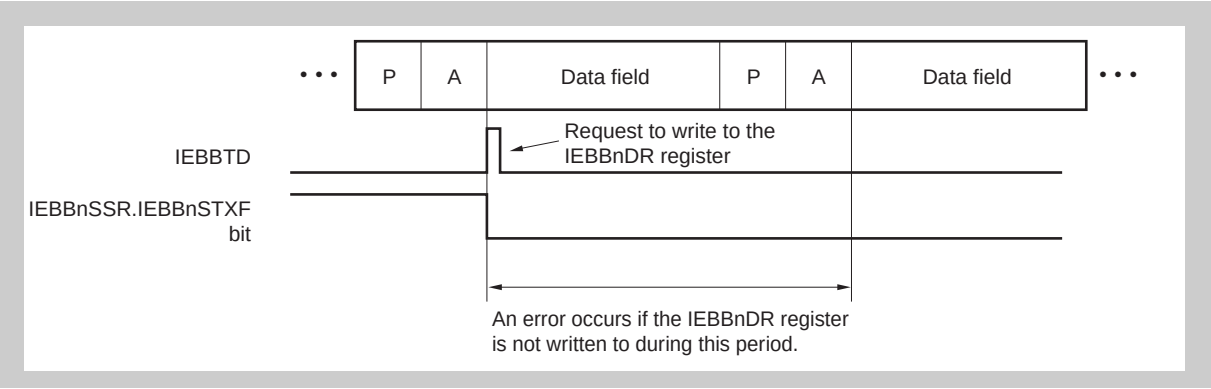

Figure 22-6 Underrun error occurrence timing

– FIFO mode:

Before data of the message length specified by the IEBBnTDL register is transmitted, if there are 0 data items to be transmitted remaining in the transmission FIFO buffer (if the IEBBnSSR.IEBBnSTXF bit = 0), an underrun error occurs if writing the next data to be transmitted to the IEBBnDR register does not finish before the end of the next data-field acknowledge bit period, and this flag is set (to 1). However, if the NACK signal is received during the acknowledge bit period, no underrun error occurs because retransmission is performed.

During inter-third-party communication, underrun errors do not occur because only timing/parity errors are detected as errors.

(e) Overrun error occurrence flag (IEBBnOVRE): Bit 3

- Set condition

  Set:

  – Single mode:

  When the data field is used to receive data during broadcast communication, an overrun error occurs if reading the IEBBnDR register does not finish between when IEBBTD occurs and when the parity period of the data field finishes, and this flag is set (to 1).

  During individual communication, data retransmission is requested by returning a NACK signal without an error, and returning the NACK signal continues until the IEBBnDR register is read. (However, the frame ends when the maximum number of bytes that can be transferred is reached.)

  During inter-third-party communication, overrun errors do not occur because only timing/parity errors are detected as errors.

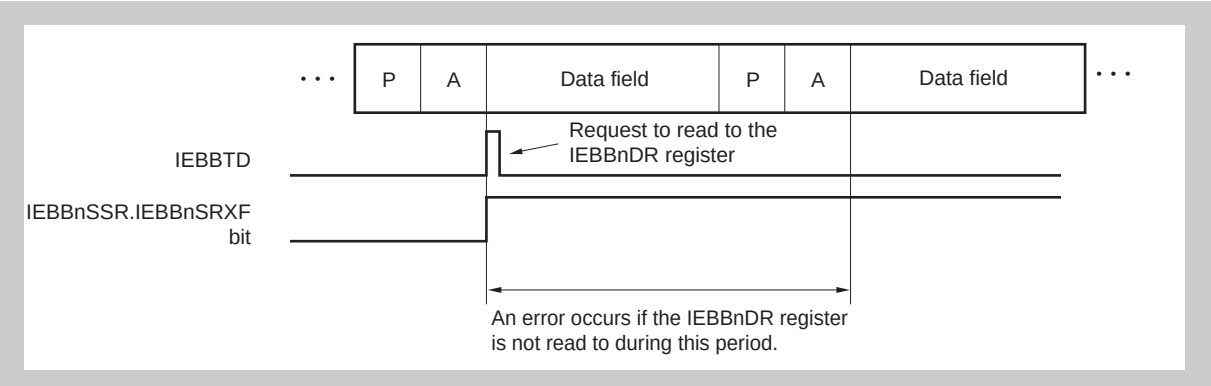

Figure 22-7 Overrun error occurrence timing

  – FIFO mode:

  During broadcast communication in communication mode 2, if there are 32 bytes of unread data in the reception FIFO buffer, an overrun error occurs if a 33rd byte of data is received, and this flag is set (to 1).

  During individual communication, data retransmission is requested by returning a NACK signal without an error, and returning the NACK signal continues until the IEBBnDR register is read. (However, the frame ends when the maximum number of bytes that can be transferred is reached.)

  If an overrun error occurs, do not read data by servicing interrupts.

  If an interrupt occurs while reading data, it might no longer be possible to read the correct data.

(f) Arbitration loss error occurrence flag (IEBBnABTE): Bit 1

- Set condition

  Set:

  If arbitration losses occur the number of times specified for the IEBBnTMS.IEBBnALC2 to IEBBnALC0 bits, this flag is set (to 1) when the last arbitration loss error occurs.

  For details about arbitration loss, see the description of the IEBBnARBF bit in 22.3.2 (18) IEBBnUSR - IEBBn unit status register.

(g) Inter-third-party communication error occurrence flag (IEBBnTRDE): Bit 0

- Set condition

  Set:

  If an inter-third-party communication error occurs at the same time as a timing error or parity error that occurs during communication that is not related to the unit (inter-third-party communication), this flag is set (to 1) at the same time as the IEBBnTIME or IEBBnPARE bit.

Caution If an error occurs before the inter-third-party communication starts even when the slave address field does not match that of the unit (for example, if the NACK signal is received when the received address does not match that of the unit in the slave address field (if the IEBBnNACE bit is set (to 1))), the IEBBnTRDE bit is not set (to 1).

Note Communication between third parties may take place in the following two cases.

1. If the address received in the slave address field does not match that of the unit (during individual communication: matching with the IEBBnUAR register, during broadcast communication: matching with the group or FFFH) and communication continues after the ACK signal has been received, the unit monitors that communication.
2. If the unit cannot respond to the received control data in the control field during broadcast communication and if communication continues, the unit monitors that communication. For example, this happens when the unit receives the control data FH from the master during broadcast communication but the slave reception enable flag of the unit is disabled (IEBBnBCR.IEBBnSRXE bit = 0). (During individual communication, the NACK signal is returned and communication ends.)

(21) IEBBnFSR - IEBBn field status register

The IEBBnFSR register is used to store the field status state of the IEBus controller when various interrupts (IEBBTD, IEBBTSTA, IEBBTERR, and IEBBTV) occur.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0050_H

Initial value 00_H

The IEBBnSSFS1 and IEBBnSSFS0 bits are reset when the IEBBnBCR.IEBBnPW bit is overwritten with a different value.

Cautions
1. If a different interrupt occurs before the IEBBnFSR register is read, the status information used at the time of the previous interrupt is overwritten with the status information used at the time of the new interrupt.
2. If an interrupt occurs during communication between third parties (during the reception of communication between other units), the IEBBnSSFS1 and IEBBnSSFS0 bits are cleared to 00. However, because the only interrupts that occur during communication between third parties are interrupts caused by errors, an inter-third-party communication error can be judged to have occurred by reading the inter-third-party communication error occurrence flag (the IEBBnTRDE bit) of the IEBBnESR register.
3. Even if the field status signal (an internal signal) changes, the IEBBnSSFS1 and IEBBnSSFS0 bits retain their previous values until an interrupt occurs.

		Master address field	
		Slave address field	
		Control data field	
		Message length field	
		Data field	

(a) Reception communication completion flag (IEBBnRTRF): Bit 7

This flag indicates that communication equivalent to the number of bytes specified by the message length has finished during reception.

- Set/clear condition

  Set:

  – Single mode: The IEBBnRTRF bit is not set (to 1).

  – FIFO mode:

    During reception, the flag is set (to 1) when the IEBBnISR.IEBBnETRF bit is set (to 1).

  Clear:

  – Single mode: The IEBBnRTRF bit always has the clear status.

  – FIFO mode:

    During reception, the flag is cleared (to 0) when the IEBBnISR.IEBBnEFMF bit is set (to 1).

Cautions
1. In the FIFO mode, if the set and clear conditions are both satisfied, setting the flag is prioritized.
2. The IEBBnRTRF bit is not cleared (to 0) by writing 1 to the IEBBnPCR.IEBBnCRPT bit.

(b) Transmission communication completion flag (IEBBnTTRF): Bit 6

This flag indicates that communication equivalent to the number of bytes specified by the message length has finished during transmission.

- Set/clear condition

  Set:

  – Single mode: The IEBBnTTRF bit is not set (to 1).

  – FIFO mode:

    During transmission, the flag is set (to 1) when the IEBBnISR.IEBBnETRF bit is set (to 1).

  Clear:

  – Single mode: The IEBBnTTRF bit always has the clear status.

  – FIFO mode:

    During transmission, the flag is cleared (to 0) when the IEBBnISR.IEBBnEFMF bit is set (to 1).

Cautions
1. In the FIFO mode, if the set and clear conditions are both satisfied, setting the flag is prioritized.
2. The IEBBnTTRF bit is not cleared (to 0) by writing 1 to the IEBBnPCR.IEBBnCTPT bit.

(c) Field status flags (IEBBnSSFS1 and IEBBnSSFS0): Bits 1 and 0

These flags store the state of the IEBus controller field status when various interrupts (IEBBTD, IEBBTSTA, IEBBTERR, and IEBBTV) occur.

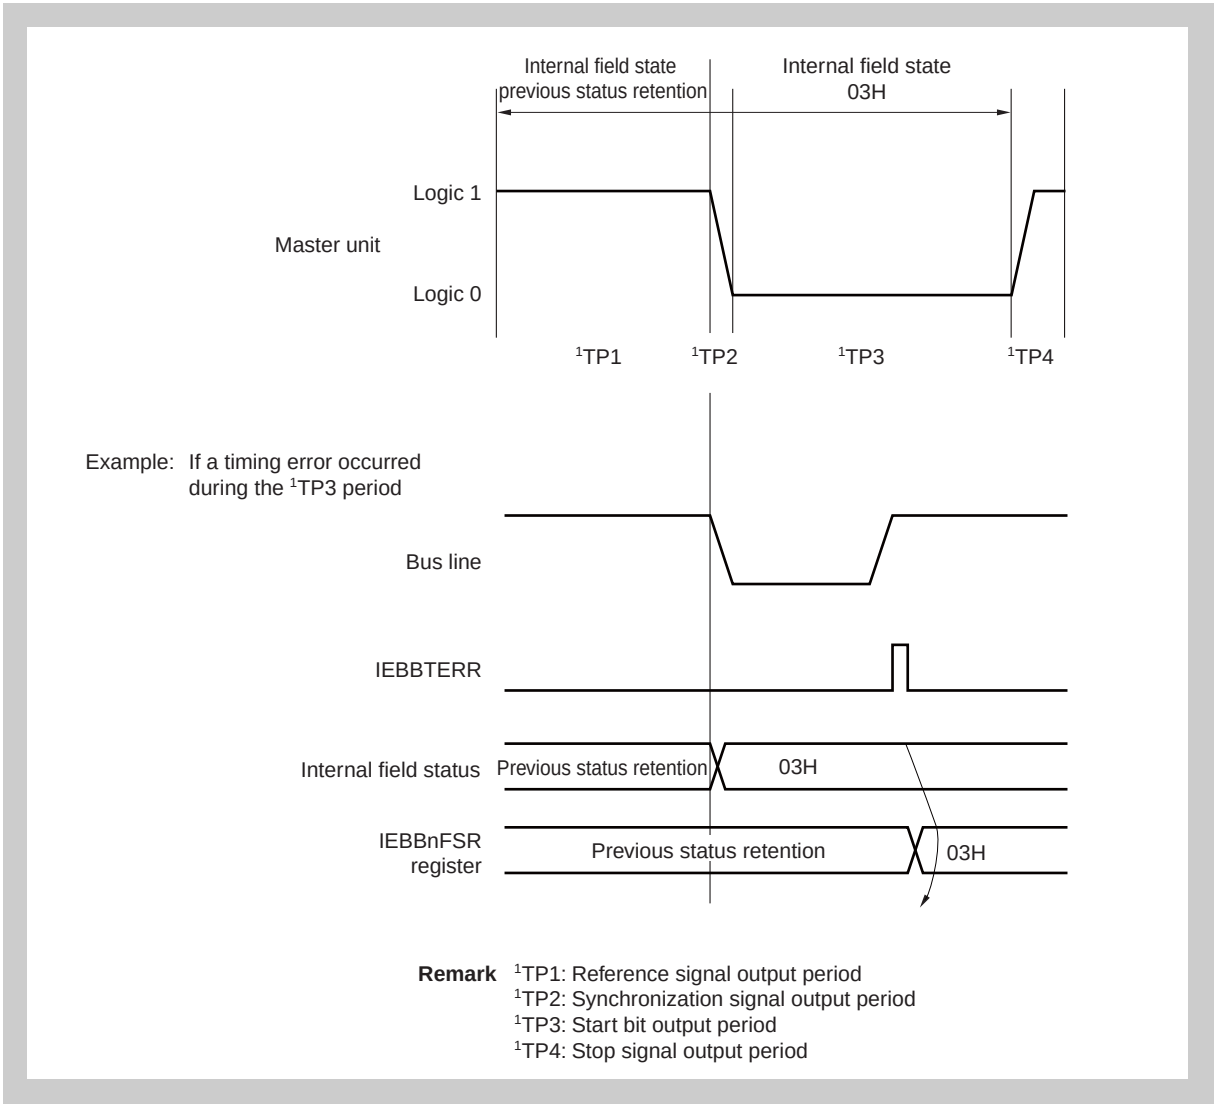

Figure 22-8 Start bit field status for the master (internal signal)

When the start bit shown in Figure 22-8 is output for the master, the previous field status value is retained until ^{1}TP1. At point ^{1}TP2 and after, the field status value is 03H. If a timing error occurs at point ^{1}TP3 and IEBBTERR is output, 03H is stored in the IEBBnFSR register.

Because IEBBTERR does not occur if communication is performed normally, the field status value is not stored in the IEBBnFSR register, and the IEBBnFSR register retains the previous value at and after point ^{1}TP2.

(22) IEBBnSCR - IEBBn success count register

The IEBBnSCR register indicates the number of remaining communication bytes.

The value specified by the IEBBnDLR register is stored in the IEBBnSCR register after the message length field processing finishes, and the count value of the counter to be decremented according to the data field $\overline{ACK}$ signal is read.

In other words, because the number of successfully communicated bytes is subtracted from the number of data bytes to be communicated, the IEBBnSCR register indicates the remaining number of bytes to be communicated.

Note that the communication completion flag (the IEBBnISR.IEBBnETRF bit) is set (to 1) when the count value reaches 00H.

The data in the IEBBnSCR register is updated when the $\overline{ACK}$ signal is received at the end of the message length field parity period or data field acknowledge bit period.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0054_H

Initial value 01_H

This register is reset when the value of the IEBBnBCR.IEBBnPW bit is overwritten with a different value.

Caution When 00H is read from the IEBBnSCR register, it is not possible to judge whether the remaining number of communication data bytes is 0 (indicating communication completion) or 256. Therefore, the communication completion flag (the IEBBnISR.IEBBnETRF bit) must also be used with this register to make this judgment.

7	6	5	4	3	2	1	0
R	R	R	R	R	R	R	R

Table 22-35 IEBBnSCR register contents

Bit								Setting	Number of remaining communication data bytes
7	6	5	4	3	2	1	0		
0	0	0	0	0	0	0	1	01H	1 byte
0	0	0	0	0	0	1	0	02H	2 bytes
...	...	...	...	...	...	...	...	...	...
0	0	0	1	0	1	0	0	20H	32 bytes
...	...	...	...	...	...	...	...	...	...
1	1	1	1	1	1	1	1	FFH	255 bytes
0	0	0	0	0	0	0	0	00H	0 bytes (communication completion) or 256 bytes

(23) IEBBnCCR - IEBBn communication count register

The IEBBnCCR register indicates the number of bytes remaining from the communication byte number specified by the communication mode.

This register indicates the number of transfer bytes.

The maximum number of transmitted bytes per frame defined in each mode (communication mode 1: 32 bytes, communication mode 2: 128 bytes) is preset to this register. The count value of the counter that is decremented during the acknowledge bit period of the data field regardless of the $\overline{\text{ACK}}$/NACK signal is read from this register. In contrast with the IEBBnSCR register, which is decremented when there is normal communication (the $\overline{\text{ACK}}$ signal), the IEBBnCCR register is decremented when one byte is communicated, regardless of the $\overline{\text{ACK}}$/NACK signal. Note that the frame completion flag (the IEBBnISR.IEBBnEFMF bit) is set (to 1) when the counter reaches 00H.

The preset value of the maximum number of transmitted bytes per frame is 20H (32 bytes) in communication mode 1 and 80H (128 bytes) in communication mode 2.

Updating of data proceeds independently of parity at the end of the ACK interval for the data field on completion of transmission (or reception) of the start bit for the preset maximum number of bytes.

Access This register is read-only, in 8-bit units.

Address <IEBBn_base> + 0058_H

Initial value 20_H

This register is reset when the value of the IEBBnBCR.IEBBnPW bit is overwritten with a different value.

Caution The value of the IEBBnCCR register is not updated by writing to the IEBBnPSR.IEBBnCMD bit.

7	6	5	4	3	2	1	0
R	R	R	R	R	R	R	R

(24) IEBBnSTC0 - IEBBn status clear register 0

The IEBBnSTC0 register is used to clear the IEBBnESR register.

Access This register is write-only, in 8-bit units.

Address <IEBBn_base> + $005C_H$

Initial value 00_H

Table 22-36 IEBBnSTC0 register contents

Bit position	Bit name	Function
7	IEBBnCLTM	This bit is used to clear the timing error flag (IEBBnESR.IEBBnTIME). 0: No operation 1: Clear the IEBBnTIME bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
6	IEBBnCLPA	This bit is used to clear the parity error flag (IEBBnESR.IEBBnPARE). 0: No operation 1: Clear the IEBBnPARE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
5	IEBBnCLNC	This bit is used to clear the NACK reception error flag (IEBBnESR.IEBBnNACE). 0: No operation 1: Clear the IEBBnNACE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
4	IEBBnCLUR	This bit is used to clear the underrun error flag (IEBBnESR.IEBBnUNRE). 0: No operation 1: Clear the IEBBnUNRE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
3	IEBBnCLOV	This bit is used to clear the overrun error flag (IEBBnESR.IEBBnOVRE). 0: No operation 1: Clear the IEBBnOVRE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
1	IEBBnCLAB	This bit is used to clear the arbitration loss error flag (IEBBnESR.IEBBnABTE). 0: No operation 1: Clear the IEBBnABTE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.
0	IEBBnCLTR	This bit is used to clear the inter-third-party communication error flag (IEBBnESR.IEBBnTRDE). 0: No operation 1: Clear the IEBBnTRDE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.

(25) IEBBnSTC1 - IEBBn status clear register 1

The IEBBnSTC1 register is used to clear the IEBBnISR.IEBBnFOVE bit.

Access This register is write-only, in 8-bit units.

Address <IEBBn_base> + 0060_H

Table 22-37 IEBBnSTC1 register contents

Bit position	Bit name	Function
0	IEBBnCLFF	This bit is used to clear the frame over error flag (IEBBnISR.IEBBnFOVE). 0: No operation 1: Clear the IEBBnFOVE bit. Writing 1 is valid, and writing 0 does not change the internal status. When the bit is read, 0 is always returned.

(26) IEBBnDR - IEBBn data register

The IEBBnDR register is used to set up the communication data. Specify the communication data (8 bits) for bits 7 to 0.

Notes
1. The IEBBnDR register consists of a write register and a read register. Therefore, data written to this register cannot be read as is. The data received during IEBus communication can be read.
2. In the FIFO mode, the data in the FIFO buffer can be transferred by continuously accessing the IEBBnDR register. (See 22.5.1 (1) Transmission FIFO buffer for details about using the transmission unit or 22.5.1 (2) Reception FIFO buffer for details about using the reception unit.)

(a) For the transmission unit

If the unit is the transmission unit (during master or slave transmission), the bits in the data field are transmitted as data bits starting with the highest bits when writing to the IEBBnDR register.

Specify the first byte of transmission data before starting communication (IEBBnBCR.IEBBnMSRQ bit = 0).

Even in the FIFO mode, write at least one byte of transmission data to the FIFO buffer before starting communication (IEBBnMSRQ bit = 0).

In the FIFO mode, the contents of the FIFO buffer are not reset in sync with the IEBBnBCR.IEBBnPW bit. Clearing the pointer value (to 0) eliminates the remaining data visible to the user. The stored data becomes undefined.

During transmission (master or slave transmission), if a data interrupt (IEBBTD) occurs, the next transmission data is written to the IEBBnDR register.

In the single mode, if a status transmission interrupt (IEBBTSTA or IEBBTV) occurs, the status data is written to the IEBBnDR register according to the control data.

(b) For the reception unit

The 1 byte of data received using the data field is read from the IEBBnDR register if the unit is the reception unit (master or slave reception). Storage is performed at the end of the data field parity period if the parity value is normal. The read value is reset by clearing the IEBBnPW bit to 0.

During reception (master or slave reception), if a data interrupt (IEBBTD) occurs, received data is read from the IEBBnDR register.

Access This register can be read or written in 8-bit units.

Address <IEBBn_base> + 0064_H

Initial value 00_H

The read value is reset when the IEBBnBCR.IEBBnPW bit is overwritten.

Cautions

1. If writing to the IEBBnDR register is not in time for transmission, an underrun error occurs and communication ends.
2. Write to the status data register IEBBnDR after a status transmission interrupt occurs and before the end of the message length field.
3. In the single mode, if the IEBBnDR register is not read before the next reception, the communication differs in the case of individual versus broadcast communication.
   - For individual communication, a NACK signal is returned for the field, and the master is requested to transmit the same data. Received data is not stored in the IEBBnDR register. If the NACK signal is returned again before the IEBBnDR register is read and the register has still not been read when the maximum number of transferable bytes is reached, frame completion (IEBBTSTA, IEBBTV) and a NACK reception error (IEBBTERR, IEBBTV) occur at the same time.
   - During broadcast communication, an overrun error occurs and communication ends. Received data is not stored in the IEBBnDR register. The overrun error flag (IEBBnOVRE) is set (to 1).
4. In the FIFO mode, if the next reception occurs before all the data received during the previous communication is read, the communication differs in the case of individual versus broadcast communication.
   - For individual communication, a NACK signal is returned for the data field, and the master is requested to transmit the same data. Received data is not stored in the FIFO buffer. If the NACK signal is returned again before all the data in the FIFO buffer is read and the FIFO buffer has still not been read when the maximum number of transferable bytes is reached, frame completion (IEBBTSTA) and a NACK reception error (IEBBTERR) occur at the same time.
   - During broadcast communication, an overrun error occurs and communication ends. Received data is not stored in the FIFO buffer. The frame over error flag (IEBBnISR.IEBBnFOVE) is set (to 1).
5. In the FIFO mode and communication mode 2, if there are 32 bytes of unread data and the next reception occurs, the communication differs in the case of individual versus broadcast communication.
   - For individual communication, a NACK signal is returned for the field, and the master is requested to transmit the same data. Received data is not stored in the FIFO buffer. If the NACK signal is returned again before the IEBBnDR register is read and reading the register has still not finished when the maximum number of transferable bytes is reached, frame completion (IEBBTSTA) and a NACK reception error (IEBBTERR) occur at the same time.
   - During broadcast communication, an overrun error occurs and communication ends. Received data is not stored in the FIFO buffer. The overrun error flag (IEBBnESR.IEBBnOVRE) is set (to 1).

22.4 Interrupt Operations

22.4.1 Interrupt request signals

Various interrupts occur in response to the eight interrupt requests below. The high level width of each interrupt signal is one P0ϕ clock cycle.

The interrupts that occur differ depending on whether the system is in the single or FIFO mode.

(1) Single mode

The causes of interrupts in the single mode are shown blow.

Table 22-38 Causes of interrupts in the single mode

Symbol	IEBBTD	IEBBTV	IEBBTERR	IEBBTSTA	Interrupt cause
IEBBnIEBE		Occurs	Occurs		Communication error (When the IEBBnISR.IEBBnIEBE bit = 1) Note that IEBBnIEBE occurs when the following bits of the IEBBnESR register = 1. • Timing error (IEBBnTIME) • Parity error (IEBBnPARE) • NACK reception error (IEBBnNACE)[a] • Underrun error (IEBBnUNRE) • Overrun error (IEBBnOVRE)
IEBBnSTRF		Occurs		Occurs	Start request (when the IEBBnISR.IEBBnSTRF bit = 1)
IEBBnSTSF		Occurs		Occurs	Status transmission request (when the IEBBnISR.IEBBnSTSF bit = 1)
IEBBnETRF		Occurs		Occurs	End of communication (When the IEBBnISR.IEBBnETRF bit = 1)
IEBBnEFMF		Occurs		Occurs	End of frame (When the IEBBnISR.IEBBnEFMF bit = 1)[a]
IEBBnFOVE					Frame over (When the IEBBnISR.IEBBnFOVE bit = 1)
WRREQ	Occurs				Transmission data write request (when the IEBBnSSR.IEBBnSTXF bit = 0)[b]
RDREQ	Occurs				Reception data read request (when the IEBBnSSR.IEBBnSRXF bit = 1) [c]

a) If the frame data ends with a NACK signal, IEBBTV and IEBBTSTA are triggered by setting the frame completion indicating bit IEBBnISR.IEBBnEFMF (to 1).
At this time, the IEBBTERR and IEBBTV interrupts are triggered by a NACK reception error.
Three interrupts (IEBBTV, IEBBTSTA, and IEBBTERR) occur at the same time.

b) During master transmission:

1. IEBBTD occurs after receiving the $\overline{\text{ACK}}$ signal, which follows message length field transmission. However, if the transfer size is one byte (the IEBBnTDL register = 01H), IEBBTD does not occur.

2. IEBBTD occurs after receiving the $\overline{\text{ACK}}$ signal, which follows data field transmission. However, IEBBTD does not occur before transmitting the final data, or after transmitting the final data and then receiving the ACK signal. More specifically, if the message length is five bytes, IEBBTD does not occur after transmitting the 4th or 5th byte. In addition, when transmitting the maximum number of transferable bytes for one frame, IEBBTD does not occur after transmitting byte number (maximum number of transferrable bytes – 1) or byte number (maximum number of transferable bytes).

During slave transmission:

1. IEBBTD occurs after receiving the $\overline{\text{ACK}}$ signal, which follows message length field transmission. However, if the transfer size is one byte or the received control bit is a status request (0H, 4H, 5H, or 6H), IEBBTD does not occur (and a status transmission interrupt occurs instead).

2. After data field transmission, the operation is the same as for *2* under During master transmission.

c) RDREQ occurs after receiving the parity bit by using the data field. However, if the self-transmitted parity bit differs from the received parity bit, there is a timing error and no interrupt occurs.

(2) FIFO mode

The causes of interrupts in the FIFO mode are shown below.

Table 22-39 Causes of interrupts in the FIFO mode

Symbol	IEBBTD	IEBBTV	IEBBTERR	IEBBTSTA	Interrupt cause
IEBBnIEBE			Occurs		Communication error (When the IEBBnISR.IEBBnIEBE bit = 1) Note that IEBBnIEBE occurs when the following bits of the IEBBnESR register = 1. • Timing error (IEBBnTIME) • Parity error (IEBBnPARE) • NACK reception error (IEBBnNACE)[a] • Underrun error (IEBBnUNRE) • Overrun error (IEBBnOVRE)[b] • Arbitration loss error (IEBBnABTE)
IEBBnSTRF					Start request (when the IEBBnISR.IEBBnSTRF bit = 1)
IEBBnSTSF					Status transmission request (when the IEBBnISR.IEBBnSTSF bit = 1)
IEBBnETRF		Occurs[c]		Occurs	End of communication (When the IEBBnISR.IEBBnETRF bit = 1)
IEBBnEFMF		Occurs[c]		Occurs	End of frame (When the IEBBnISR.IEBBnEFMF bit = 1)[a]
IEBBnFOVE			Occurs		Frame over (When the IEBBnISR.IEBBnFOVE bit = 1)[b]
WRREQ	Occurs[d]				Transmit data write request
RDREQ		Occurs[e]			Receive data write request Parity

a) If the frame data ends with a NACK signal, IEBBTV and IEBBTSTA are triggered by setting the frame completion indicating bit IEBBnISR.IEBBnEFMF (to 1).
Note that the IEBBTERR interrupt is triggered by a NACK reception error.
Three interrupts (IEBBTV, IEBBTSTA, and IEBBTERR) occur at the same time, regardless of transmission or reception.

b) If data is received during the broadcast communication for the next frame while the FIFO buffer is full due to the reception of the previous frame and the data has not been read, the IEBBnISR.IEBBnFOVE and IEBBnESR.IEBBnOVRE bits are set (to 1) at the same time.

c) IEBBTV occurs based on the same conditions and at the same timing as IEBBTSTA. (For details, see Table 22-40 $\overline{\text{ACK}}$/NACK for IEBBnETRF and IEBBnEFMF.)
For individual communication:
1. Transmission-side device

IEBBnETRF:
This is set (to 1) after receiving the $\overline{\text{ACK}}$ signal. If the NACK signal is received, communication does not end.

IEBBnEFMF: This is set (to 1) after reception regardless of the $\overline{\text{ACK}}$/NACK signal.

2. Reception-side device

IEBBnETRF:
This is set (to 1) after transmitting the $\overline{\text{ACK}}$ signal. If the NACK signal is transmitted, communication does not end.

IEBBnEFMF:
This is set (to 1) after transmission regardless of the $\overline{\text{ACK}}$/NACK signal.
The NACK signal is output when there is no room in the reception FIFO buffer or when there is a data retransmission request due to a parity mismatch. Not returning an ACK signal to the reception side as the bus status after exiting communications due to the detection of an error does not constitute a NACK signal. In this case, IEBBTSTA and IEBBTV do not occur because the system does not enter the frame completion status.

For broadcast communication:
For broadcast communication, no $\overline{\text{ACK}}$ signal is returned from the slave. Therefore, it is judged that the NACK signal was successfully returned regardless of master transmission or slave reception, and the IEBBnETRF or IEBBnEFMF interrupt occurs.

d) This occurs when the conditions specified by the IEBBnTMS.IEBBnSLTI1 and IEBBnSLTI0 bits are satisfied. The occurrence timing is after receiving the $\overline{\text{ACK}}$ signal, which follows data field transmission. However, if the transfer size is one byte or the received control bit is a status request (0H, 4H, 5H, or 6H), IEBBTD does not occur.

e) 1. Transmission-side device
RDREQ is not set under this condition.
2. Reception-side device
RDREQ is set (to 1) when the conditions specified by the IEBBnTMS.IEBBnSLRI1 and IEBBnSLRI0 bits are satisfied (after confirming that a normal parity bit value has been received).
If there is a parity bit mismatch, RDREQ is not set (to 1) because the conditions are not satisfied.
On normal completion or frame completion, RDREQ interrupt sources are masked.

Table 22-40 $\overline{\text{ACK}}$/NACK for IEBBnETRF and IEBBnEFMF

Field status	Individual communication				Broadcast communication			
	IEBBnETRF		IEBBnEFMF		IEBBnETRF		IEBBnEFMF	
	$\overline{\text{ACK}}$	NACK	$\overline{\text{ACK}}$	NACK	$\overline{\text{ACK}}$	NACK	$\overline{\text{ACK}}$	NACK
Master transmission	Occurs	Does not occur	Occurs	Occurs	–	Occurs	–	Occurs
Master reception	Occurs	Does not occur	Occurs	Occurs	–	–	–	–
Slave transmission	Occurs	Does not occur	Occurs	Occurs	–	–	–	–
Slave reception	Occurs	Does not occur	Occurs	Occurs	–	Occurs	–	Occurs

Note The IEBBTV usage method is shown below.

1. Generating IEBBTV before communication finishes (when the IEBBnTMS.IEBBnSLRI1 and IEBBnSLRI0 bit settings are 32 bytes or less)
   This operation is not generally performed in communication mode 1. (It can be performed but is not.) The operation is performed in communication mode 2.
   – Use IEBBTV to check the number of data bytes received by the FIFO buffer, and then perform a readout operation. (Be sure to check the number because the IEBBTV interrupt servicing is assumed to be late.)
   – For IEBBTSTA (communication completion/frame completion), check the status.
   – Because the status is changed after receiving data, the interrupt priority is IEBBTV followed by IEBBTSTA.
2. If not generating IEBBTV during communication (if the IEBBnSLRI1 and IEBBnSLRI0 bit settings are 32 bytes)

   Use communication mode 1. (Communication mode 2 can also be used.)
   – Communication mode 1

   Mask IEBBTV (so it is not used).
   Use IEBBTSTA (communication completion/frame completion) to check the number of data bytes in the FIFO buffer, and then check the readout and status changes.
   – Communication mode 2

   Perform the same operations as in 1.

22.4.2 Interrupt judgment examples

Interrupt judgment examples for the single mode are shown below.

(1) When using IEBBTD

IEBBn transmission/reception must be checked by issuing an IEBBTD interrupt.

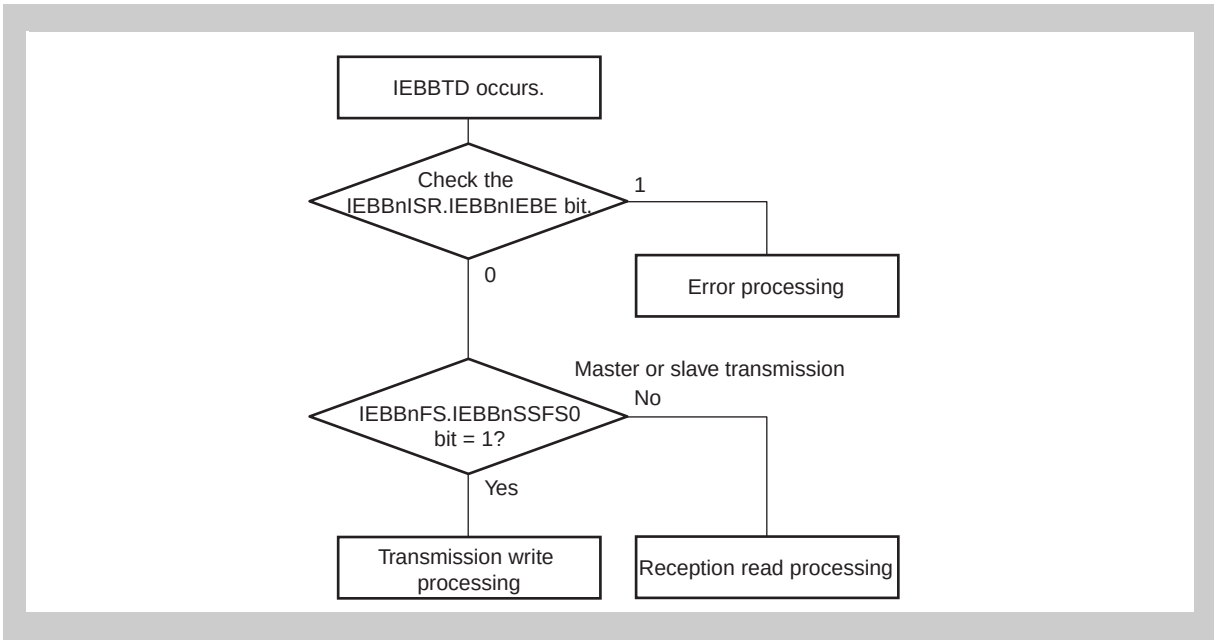

Figure 22-9 IEBBTD interrupt judgment example

Caution Even if IEBBTD occurs, an error might occur depending on when the interrupt is handled.

Such errors include timing errors after IEBBTD occurs. To increase data processing reliability, only handle data after using the IEBBnISR.IEBBnIEBE bit to make sure that no error has occurred.

(2) When using IEBBTERR

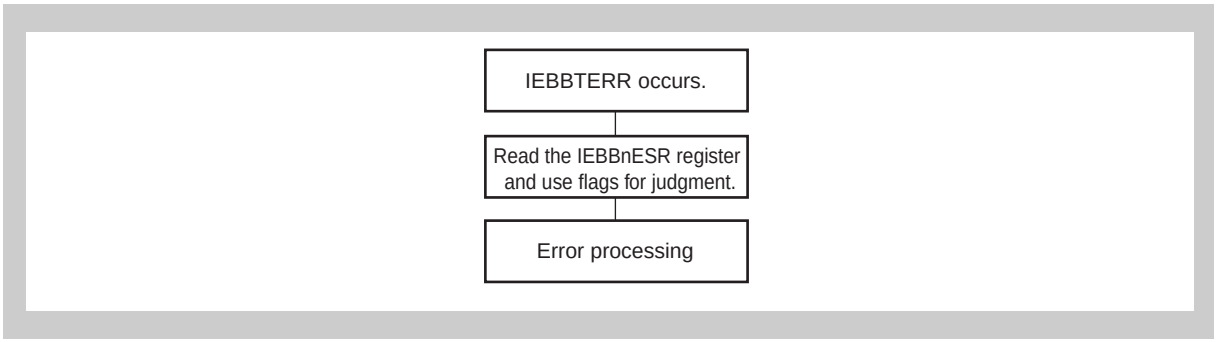

Figure 22-10 IEBBTERR interrupt judgment example

(3) When using IEBBTSTA or IEBBTV

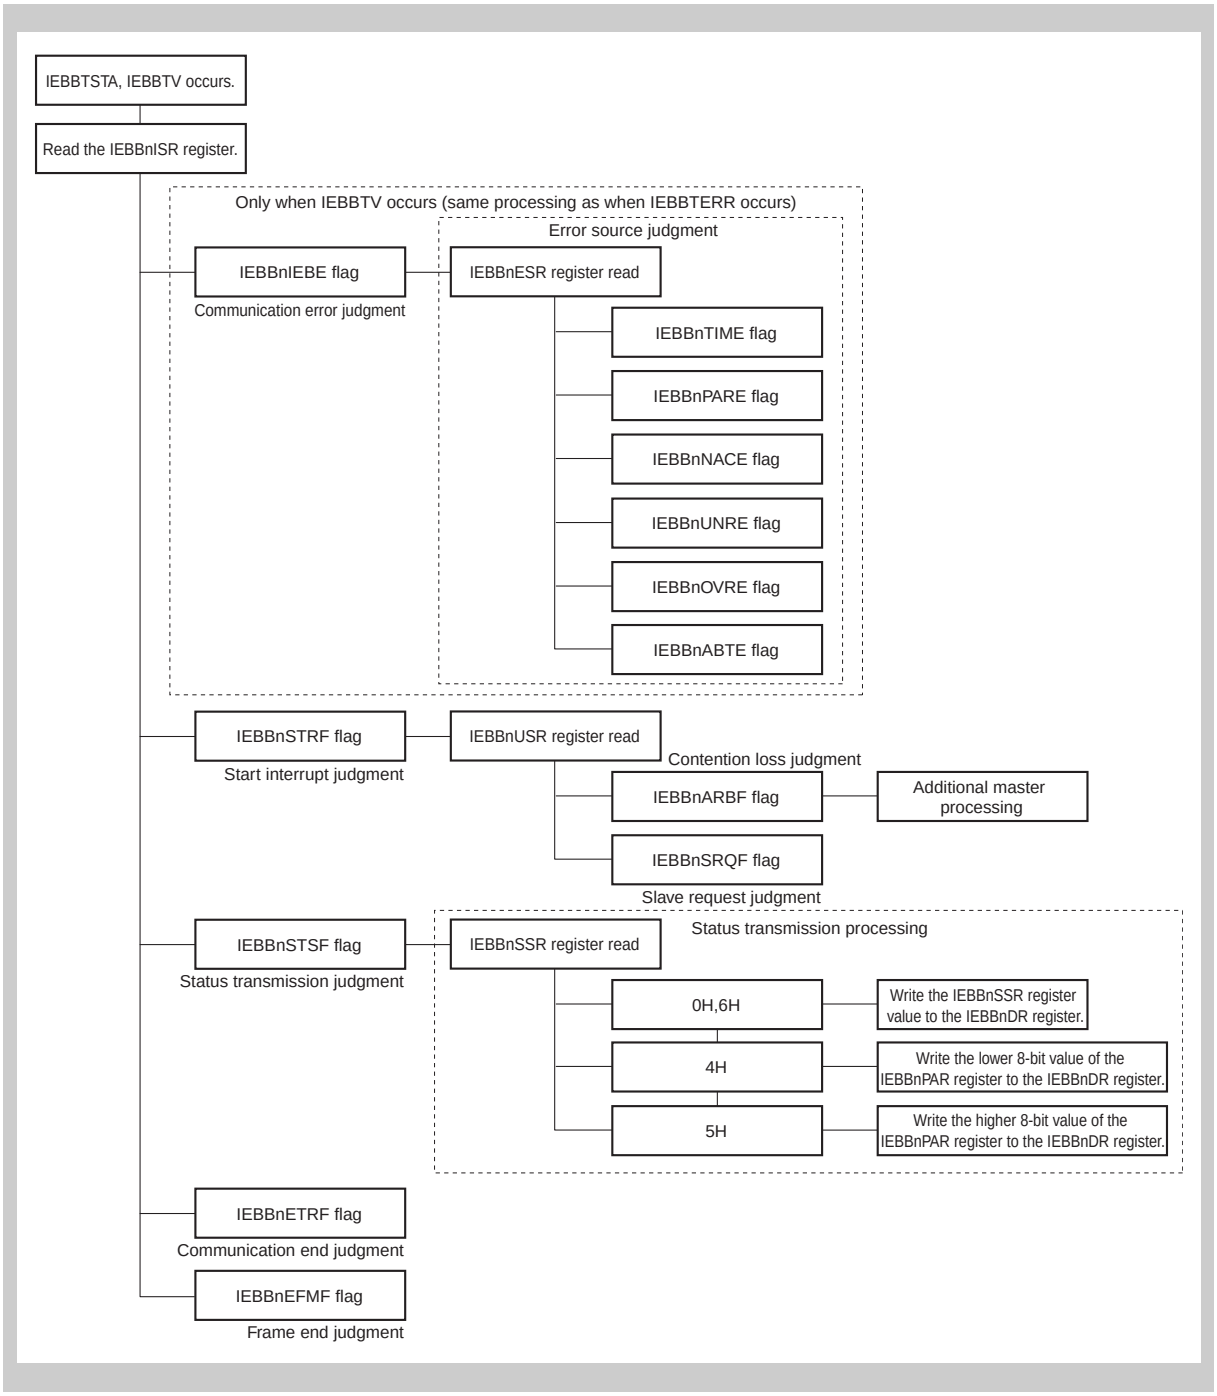

Figure 22-11 IEBBTSTA and IEBBTV interrupt judgment examples

22.5 Operation

22.5.1 FIFO

(1) Transmission FIFO buffer

When the IEBBnTMS.IEBBnFMDE bit = 1, data can be stored in the FIFO buffer while automatically incrementing the FIFO buffer pointer for writing by continuously writing transmission data to the IEBBnDR register. The FIFO buffer size is 8 bits x 32 stages.

When the transfer is started, the data indicated by the load pointer is transferred. After the transfer finishes, the load pointer is incremented. The initial value for the write pointer and load pointer is 0.

The IEBBnBSR.IEBBnTFLF bit is set (to 1) when there are 32 bytes of data in the FIFO buffer, and the transmission FIFO buffer overwrite flag (IEBBnBSR.IEBBnFOVW) is set (to 1) when a 33rd byte of data is written while the IEBBnTFLF bit = 1. At this time, the write data is ignored and the write pointer is not changed.

The data below can be written when one byte is transferred while the IEBBnTFLF bit = 1 and then the bit is cleared to 0.

If the write is not in time for data loading, an underrun error occurs.

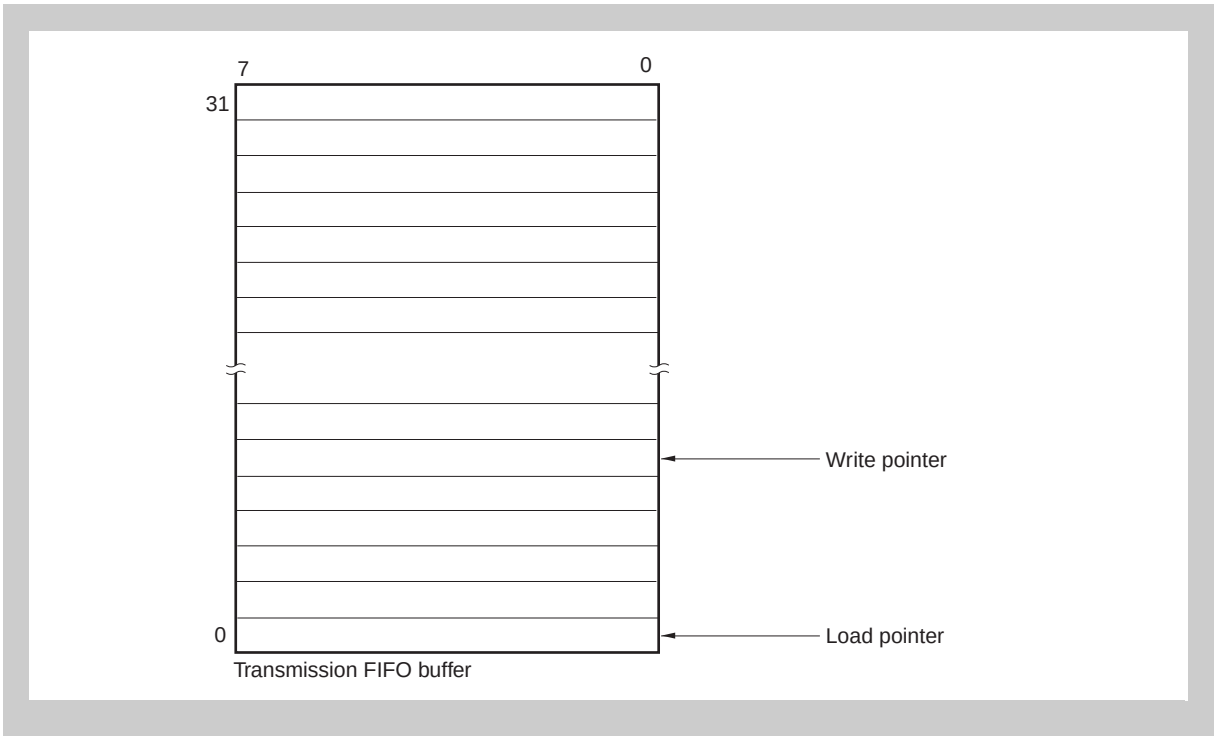

Figure 22-12 Transmission FIFO buffer

(2) Reception FIFO buffer

When the IEBBnTMS.IEBBnFMDE bit = 1, the received data is stored at the address indicated by the storage pointer. The storage pointer is incremented after storing the data. Data is stored in the FIFO buffer at the end of the data field parity period if the parity value is normal. The FIFO buffer size is 8 bits x 32 stages.

By reading the IEBBnDR register, the data in the FIFO buffer can be read while automatically incrementing the read pointer. The initial value for the read pointer and storage pointer is 0.

If there are 32 bytes of unread data in the FIFO buffer, the operation when the next data is received is as follows.

- During individual communication: No data is stored, a NACK signal is returned, and data retransmission is requested.
- During broadcast communication: No data is stored and an overrun error occurs.

  If the IEBBnDR register is read again after reading the received data that has been stored finishes (when the read pointer = the storage pointer), the read pointer is not changed, and the over-read flag (IEBBnBSR.IEBBnFOVR bit) is set (to 1).

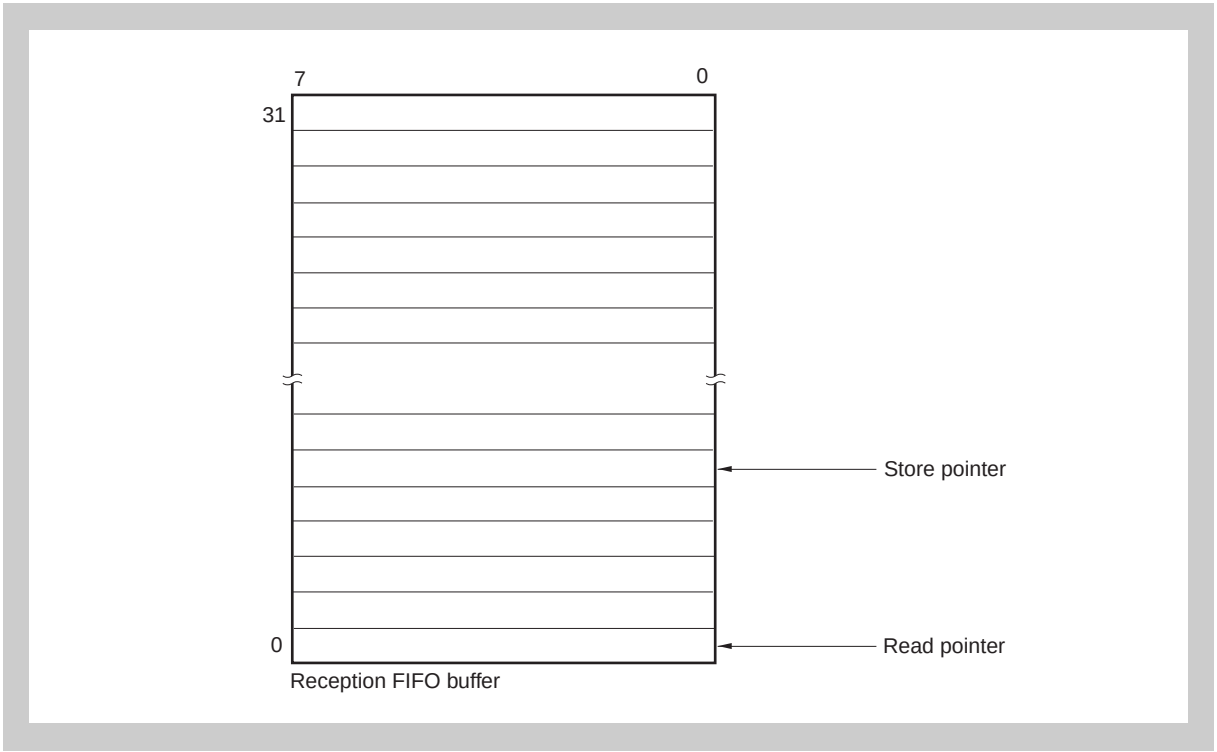

Figure 22-13 Reception FIFO buffer

22.5.2 Initial settings

After setting the IEBBnBCR.IEBBnPW bit to 1, set up the registers below, and then start communication processing.

Table 22-41 Initial setup

Register name	Function	Example
IEBBnPSR	Operation clock and communication mode settings	80H
IEBBnUAR	Set a unit address.	101H
IEBBnCKS	Clock Selection	15H
IEBBnTMS	Communication control	01H[a]

a) For use in the single mode, the initial values do no have to be changed.

22.5.3 Master transmission (single mode)

The unit transmits data and commands to the slave unit as the master.

Data interrupts are used to write transmission data to the IEBBnDR register for each one-byte transfer.

(1) Register settings

After specifying the initial settings in 22.5.2 Initial settings, set up the registers below before starting communication.

Table 22-42 Standard initial processing

Register name	Function	Example
IEBBnSAR	Communication partner unit address	102H
IEBBnCDR or IEBBnTCD	Control data (AH, BH, EH, FH)	FH
IEBBnDLR	Message length	02H
IEBBnDR	Data (1st byte of data)	11H

Table 22-43 Communication startup processing

Register name	Function	Example
IEBBnBCR	Communication startup processing	C8H

(c) Data interrupt CPU processing example

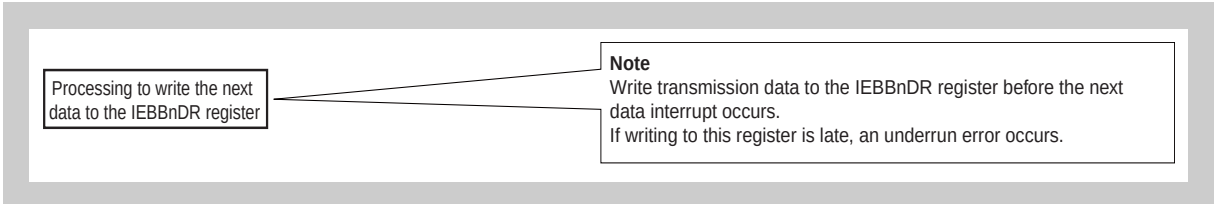

Figure 22-17 Data interrupt CPU processing

22.5.4 Master transmission (FIFO mode)

The unit transmits data and commands to the slave unit as the master.

Transmission data is written into the buffer in advance, and then a master request is issued.

(1) Register settings

After specifying the initial settings in 22.5.2 Initial settings, set up the registers below before starting communication.

Table 22-44 Standard initial processing

Register name	Function	Example
IEBBnSAR	Communication partner unit address	102H
IEBBnCDR or IEBBnTCD	Control data (AH, BH, EH, FH)	FH
IEBBnTDL	Message length	02H
IEBBnDR	Data (all data to be transmitted)	11H, …

Table 22-45 Communication startup processing

(3) Interrupt servicing examples

(a) Transmission completion interrupt (IEBBTV, IEBBTSTA) CPU processing flow example

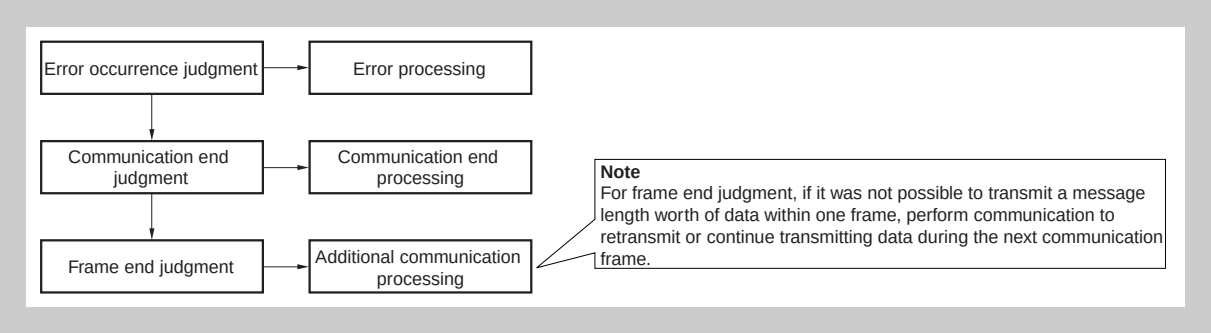

Figure 22-19 Transmission completion interrupt (IEBBTV, IEBBTSTA) CPU processing flow example

22.5.5 Master reception (single mode)

The unit receives data and commands from the slave unit as the master. Because the slave transfers the message length field in the case of master reception, indicate the message length of data to be transmitted to the slave, such as during other communication. Read the received data one byte at a time by using data interrupts.

(1) Register settings

After specifying the initial settings in 22.5.2 Initial settings, set up the registers below before starting communication.

Table 22-46 Standard initial processing

Register name	Function	Example
IEBBnSAR	Communication partner unit address	102H
IEBBnCDR or IEBBnTCD	Control data (0H, 3H, 4H, 5H, 6H, 7H)	7H

22.5.7 Slave transmission (single mode)

The unit transfers data and commands to the master unit as a slave.

Data interrupts are used to write transmission data to the IEBBnDR register for each one-byte transfer.

(1) Register settings

After specifying the initial settings in 22.5.2 Initial settings, set up the registers below before starting communication.

Table 22-50 Standard initial processing

Register name	Function	Example
IEBBnDLR	Message length (other than during slave status transmission)	02H
IEBBnDR	Data (1st byte of data)	11H

Caution When starting slave transmission, information such as the value to be set to the message length register (IEBBnDLR) and which data is to be returned (the value to be set to the IEBBnDR register) must be assigned in advance by the master, such as during separate communication.

Table 22-51 Communication startup processing

Register name	Function	Example

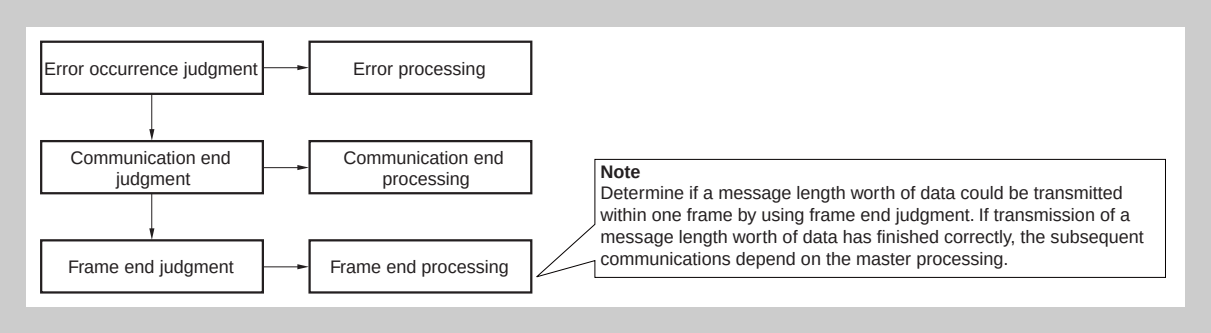

Figure 22-36 Transmission completion interrupt (IEBBTV, IEBBTSTA) CPU processing flow example

(b) Slave status transmission request processing flow example

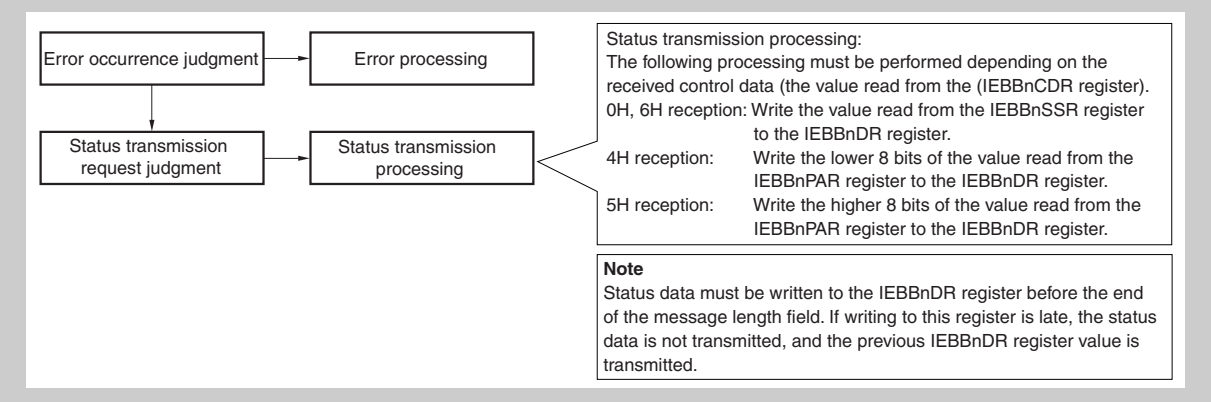

Figure 22-37 Slave status transmission request processing flow

In the FIFO mode, if the unit loses a conflict between a unit master transmission request and a slave transmission request addressed to the unit, because the slave transmission enable flag (IEBBnBCR.IEBBnSTXE) is not set (to 1) for the unit, a NACK signal is transmitted using the control data field and communication ends. Next, specify the slave transmission data for the FIFO buffer, set the slave transmission enable flag (to 1), and prepare to receive another slave transmission request from the master.

22.5.9 Slave reception (single mode)

The unit receives data and commands from the master unit as a slave.

Read the received data one byte at a time by using data interrupts.

(1) Register settings

After specifying the initial settings in 22.5.2 Initial settings, set up the registers below before starting communication.

22.7 Functions

22.7.1 IEBus communication protocol

The communication protocol of the IEBus is as follows.

(1) Multi-task mode

All the units connected to the IEBus can transfer data to the other units.

(2) Broadcast communication

Communication between one unit and multiple units can be performed as follows.

- Group broadcast communication: Broadcast communication to group units
- All-unit broadcast communication: Broadcast communication to all units

(3) Effective transmission speed

The effective transfer rate is in communication mode 1 or communication mode 2. (This product does not support mode 0 for the effective transfer rate.)

- Communication mode 1: Approx. 18 kbps
- Communication mode 2: Approx. 27 kbps

Caution Different modes (communication mode 1, communication mode 2) must not be mixed on one IEBus.

(4) Communication mode

Data transfer is executed in half-duplex asynchronous communication mode.

(5) Access control: CSMA/CD (Carrier Sense Multiple Access with Collision Detection)

The priority of the IEBus is as follows:

1. Broadcast communication takes precedence over individual communication (communication from one unit to another).
2. The lower master address takes precedence.

(6) Communication scale

The communication scale of IEBus is as follows:

- Number of units: 50 maximum
- Cable length: 150 m maximum (when twisted pair cable is used)

Caution The communication scale in an actual system differs depending on the characteristics of the cables, etc., constituting the IEBus driver/receiver and IEBus.

22.7.2 Determination of bus mastership (arbitration)

An operation to occupy the bus is performed when a unit connected to the IEBus controls the other units. This operation is called arbitration.

When multiple units simultaneously start transmission, arbitration is used to grant one of the units permission to occupy the bus.

Because only one unit is granted bus mastership as a result of arbitration, the priority conditions of the bus are predetermined as follows.

Caution Bus mastership is canceled if communication is aborted.

(1) Priority by communication type

Broadcast communication (communication from one unit to multiple units) takes precedence over normal communication (communication from one unit to another).

(2) Priority by master address

If the communication type is the same, communication with the lower master address takes precedence.

A master address consists of 12 bits, with unit 000H having the highest priority and unit FFFH having the lowest priority.

22.7.3 Communication mode

The IEBus has three communication modes, each of which has a different transfer rate. This module supports communication modes 1 and 2. The transfer rate and the maximum number of transfer bytes per communication frame in communication modes 1 and 2 are shown below.

Table 22-56 Transfer rate and maximum number of transfer bytes in each communication mode

Communication mode	Maximum number of transfer bytes (bytes/frame)	Effective transfer rate[a]
1	32 bytes/frame	Approx. 18 kbps
2	128 bytes/frame	Approx. 27 kbps

a) Effective transfer rate when the maximum number of transfer bytes is transmitted

Select the communication mode for each unit connected to the IEBus before starting communication. If the communication mode of the master unit and that of the partner unit (slave unit) are not the same, communication is not correctly executed.

22.7.4 Communication address

For the IEBus, each unit is assigned a specific 12-bit address. This communication address consists of the following identification numbers.

- Higher 4 bits: Group number (number to identify the group to which each unit belongs)
- Lower 8 bits: Unit number (number to identify each unit in a group)

22.7.5 Broadcast communication

Normally, transmission or reception is performed between the master unit and its partner slave unit on a one-to-one basis. During broadcast communication, however, multiple slave units exist and the master unit executes transmission to these slave units. Because multiple slave units exist, the NACK signal is returned by the communicating slave unit as an acknowledge bit.

Whether broadcast communication or normal communication is to be executed is selected by the broadcast bit. (For details about this bit, see 22.7.6 (2) Broadcast bit.)

Broadcast communication is classified into two types: group-unit broadcast communication and all-unit broadcast communication. Group-unit broadcast and all-unit broadcast are identified by the value of the slave address. (For the slave address, see 22.7.6 (4) Slave address field.)

(1) Group-unit broadcast communication

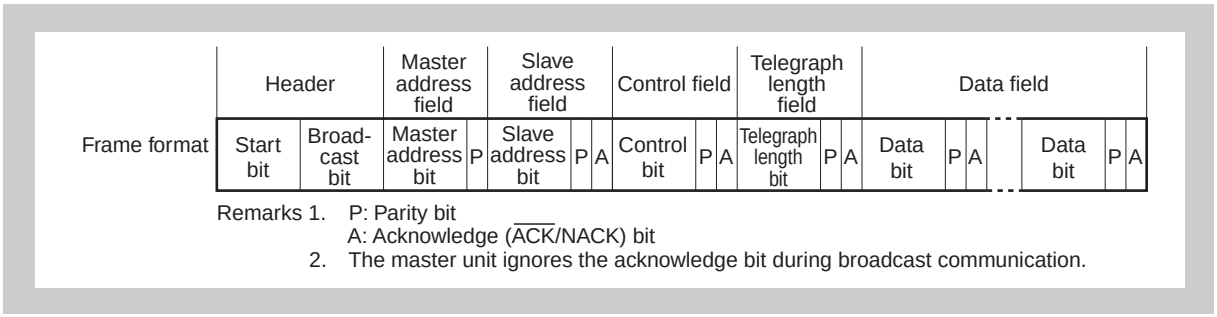
Broadcast communication is performed to the units in a group identified by the group number indicated by the higher 4 bits of the communication address.

(2) All-unit broadcast communication

Broadcast communication is performed to all the units, regardless of the value of the group number.

22.7.6 IEBus transfer format

The IEBus transfer signal format is shown in Figure 22-56.



Remarks 1. P: Parity bit
A: Acknowledge ($\overline{\text{ACK}}$/NACK) bit
2. The master unit ignores the acknowledge bit during broadcast communication.

Figure 22-56 IEBus transfer signal format

(1) Start bit

The start bit is a signal that informs the other units of the start of a data transfer.

The unit that is to start a data transfer outputs a low-level signal (start bit) for a specific time, and then starts outputting the broadcast bit.

If another unit has already output its start bit when one unit is to output the start bit, this unit does not output the start bit and instead waits for completion of output of the start bit by the other unit. When the output of the start bit by the other unit is complete, the unit starts outputting the broadcast bit in synchronization with the completion of the start bit output by the other unit.

The units other than the one that started communication detect this start bit, and enter the reception status.

(2) Broadcast bit

This bit indicates whether the master selects one slave (individual communication) or multiple slaves (broadcast communication) as the other party of communication.

When the broadcast bit is 0, it indicates broadcast communication. When it is 1, individual communication is indicated. Broadcast communication is classified into two types: group-unit communication and all-unit communication. These communication types are identified by the value of the slave address. (For the slave address, see 22.7.6 (4) Slave address field.)

Because multiple slave units exist as a partner slave unit of communication in the case of broadcast communication, the NACK signal is returned as an acknowledge bit in each field subsequent to the master address field.

If multiple units start transmitting a communication frame at the same time, broadcast communication takes precedence over individual communication, and wins in arbitration.

If one unit occupies the bus as the master, the value set to the broadcast request flag (the IEBBnBCR.IEBBnALRQ bit) is output.

(3) Master address field

The master address field is output by the master to inform a slave of the master's address.

The configuration of the master address field is shown in Figure 22-57.

If multiple units start transmitting the broadcast bit at the same time, the master address field makes a judgment of arbitration.

The master address field compares the data it outputs with the data on the bus each time it has output one bit. If the master address output by the master address field is found to differ from the data on the bus as a result of comparison, it is assumed that the master has lost arbitration.

As a result, the master stops transmission and enters the reception status. Because the IEBus is configured of wired AND, the unit having the smallest master address of the units participating in arbitration (arbitration masters) wins arbitration.

After a 12-bit master address has been output, only one unit remains in the transmission status as one master unit.

Next, this master unit outputs a parity bit, determines the master address of other unit, and starts outputting a slave address field.

If one unit occupies the bus as the master, the address specified by the IEBBnUAR register is output.

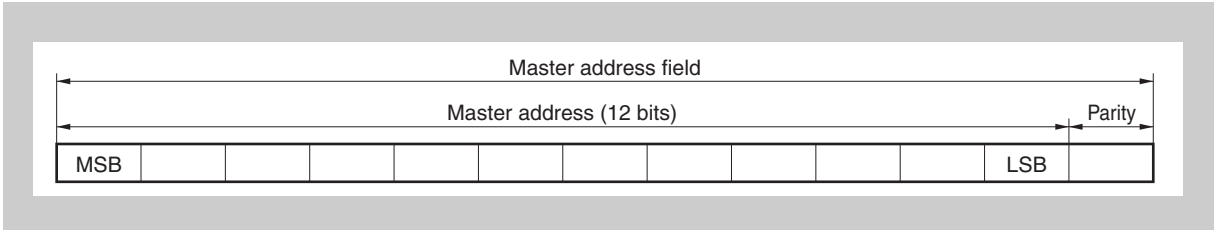


Figure 22-57 Master address field

(4) Slave address field

The master outputs the address of the unit with which it is to communicate.

The configuration of the slave address field is shown in Figure 22-58.

A parity bit is output after a 12-bit slave address has been transmitted to prevent the wrong slave address from being received by mistake. Next, the master unit detects an $\overline{\text{ACK}}$ signal from the slave unit to confirm that the slave unit exists on the bus. The master unit starts outputting the control field after detecting the $\overline{\text{ACK}}$ signal. During broadcast communication, however, the master does not confirm the acknowledge bit and instead starts outputting the control field.

The slave unit outputs the $\overline{\text{ACK}}$ signal if its slave address matches and if the slave detects that the parities of both the master address and slave address are even. The slave unit judges that the master address or slave address has not been correctly received and outputs the NACK signal if the parities are odd. At this time, the master unit is in the standby (monitor) status, and communication ends.

During broadcast communication, the slave address is used to identify group-unit broadcast or all-unit broadcast, as follows:

If the slave address is FFFH: All-unit broadcast communication

If the slave address is not FFFH: Group-unit broadcast communication

Note The group No. during group-unit broadcasting communication is the value of the higher 4 bits of the slave address.

If one unit occupies the bus as the master, the address specified by the IEBBnSAR register is output.

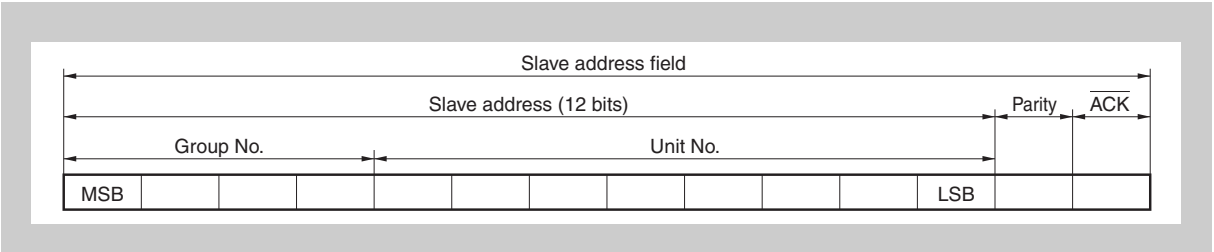

Figure 22-58 Slave address field

(5) Control data field

The master uses this field to output the operation it requires the slave to perform.

The configuration of the control field is shown in Figure 22-59.

If the parity following the control bit is even and the slave unit can execute the function required by the master unit, the slave unit outputs an $\overline{ACK}$ signal and starts outputting the message length field. If the slave unit cannot execute the function required by the master unit even if the parity is even, or if the parity is odd, the slave unit outputs the NACK signal, and returns to the standby (monitor) status.

The master unit starts outputting the message length field after detecting the $\overline{ACK}$ signal.

If the master detects the NACK signal, the master unit enters the standby status, and communication ends. During broadcast communication, however, the master unit does not confirm the acknowledge bit and starts outputting the message length field.

If one unit occupies the bus as the master, the value set to the IEBBnTCD register is output.

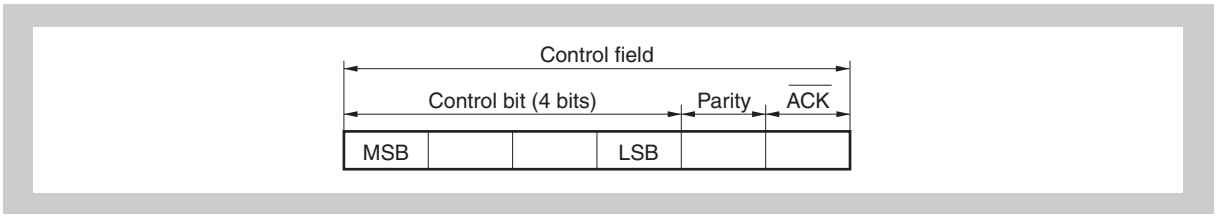

Figure 22-59 Control field

The contents of the control bits are shown below.

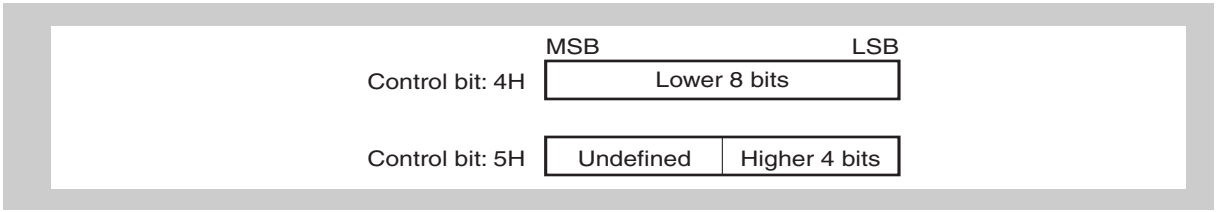
Table 22-57 Control bit contents

Bit 3[a]	Bit 2	Bit 1	Bit 0	Function
0	0	0	0	Read slave status
0	0	0	1	Undefined
0	0	1	0	Undefined
0	0	1	1	Read data and lock[b]
0	1	0	0	Read lock address (lower 8 bits)[c]
0	1	0	1	Lock address reading (higher 4 bits)[c]
0	1	1	0	Slave status reading and unlocking[b]
0	1	1	1	Read data
1	0	0	0	Undefined
1	0	0	1	Undefined
1	0	1	0	Command writing and locking[b]
1	0	1	1	Data writing and locking[b]
1	1	0	0	Undefined
1	1	0	1	Undefined
1	1	1	0	Write command
1	1	1	1	Write data

a) The message length bit of the message length field and data transfer direction of the data field change as follows depending on the value of bit 3 (MSB).
If bit 3 is 1: Transfer from master unit to slave unit
If bit 3 is 0: Transfer from slave unit to master unit

b) This is a control bit that specifies locking or unlocking. (For details, see 22.7.7 (4) Locking and unlocking.)

c) The lock address is transferred in 1-byte (8-bit) units and is configured as follows:



If the control bit received from the master unit is not as shown in Table 22-58, the unit locked by the master unit rejects acknowledging the control bit, and outputs the NACK signal.

Table 22-58 Control field for locked slave unit

Bit 3	Bit 2	Bit 1	Bit 0	Function
0	0	0	0	Read slave status
0	1	0	0	Lock address reading (lower 8 bits)
0	1	0	1	Lock address reading (higher 4 bits)

In addition, units for which locking is not set up by the master unit reject acknowledgment and output a NACK signal when the control data shown in Table 22-59 is acknowledged.

Table 22-59 Control field for unlocked slave unit

Bit 3	Bit 2	Bit 1	Bit 0	Function
0	1	0	0	Lock address reading (lower 8 bits)
0	1	0	1	Lock address reading (higher 4 bits)

Table 22-60 Control field $\overline{\text{ACK}}$ signal response conditions (when the received control data is 0H, 3H, 4H, 5H, 6H, or 7H)

Communication target (IEBBnUSR. IEBBnSRQF bit) Slave specification = 1 No specification = 0	Lock status (IEBBnUSR. IEBBnLCKF bit) Lock = 1 No lock = 0	Master unit judgment (IEBBnPAR register match) Lock request unit = 1 Other = 0	Slave transmission enabled (IEBBnBCR. IEBBnSTXE bit)	Slave reception enabled (IEBBnBCR. IEBBnSRXE bit)	Received control data					
					0H	3H	4H	5H	6H	7H
1	0	don't care	0	don't care	A	N	N	N	A	N
			1		A	A	N	N	A	A

		1	0		A	N	A	A	A	N
			1		A	A	A	A	A	A
Other than the above					N					

Note A: Slave transmission is performed. (The $\overline{\text{ACK}}$ signal is returned.)

N: Slave transmission is not performed. (The NACK signal is returned.)

Caution If the received control data is other than the data shown in the above table, N is unconditionally assumed. (Slave transmission is not performed (and the NACK signal is returned).)

Table 22-61 Control field $\overline{\text{ACK}}$ signal response conditions (when the received control data is AH, BH, EH, or FH)

Communication target (IEBBnUSR. IEBBnSRQF bit) Slave specification = 1 No specification = 0	Lock status (IEBBnUSR. IEBBnLCKF bit) Lock = 1 No lock = 0	Master unit judgment (IEBBnPAR register match) Lock request unit = 1 Other = 0	Slave transmission enabled (IEBBnBCR. IEBBnSTXE bit)	Slave reception enabled (IEBBnBCR. IEBBnSRXE bit)	Received control data			
					AH	BH	EH	FH
1	0	don't care	don't care	1	A			
	1	1						
Other than the above					N			

Note A: Slave transmission is performed. (The $\overline{\text{ACK}}$ signal is returned.)

N: Slave transmission is not performed. (The NACK signal is returned.)

Caution If the received control data is other than the data shown in the above table, N is unconditionally assumed. (Slave transmission is not performed (and the NACK signal is returned).)

(6) Message length field

This field is output by the transmission side to inform the reception side of the number of bytes of the transmit data.

The configuration of the message length field is shown in Figure 22-60.

Table 22-62 shows the relationship between the message length bit and the number of transmission data bytes.

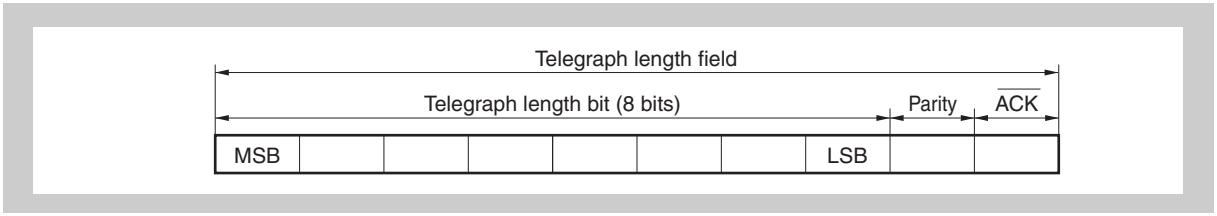

Figure 22-60 Message length field

Table 22-62 Contents of the message length bit

Message length bit (hexadecimal)	Number of transmission data bytes
01H	1 byte
02H	2 bytes
...	...
FFH	255 bytes
00H	256 bytes

The operation of the message length field differs depending on whether the master transmits data (when control bit 3 is 1) or receives data (when control bit 3 is 0).

(a) During master transmission

The message length bit and parity bit are output by the master unit and the synchronization signals of bits are output by the master unit. When the slave unit detects that the parity is even, it outputs the $\overline{\text{ACK}}$ signal, and starts outputting the data field. During broadcast communication, however, the slave unit outputs the NACK signal.

If the parity is odd, the slave unit judges that the message length bit has not been correctly received, outputs the NACK signal, and returns to the standby (monitor) status. At this time, the master unit also returns to the standby status, and communication ends.

(b) Master reception

The message length bit and parity bit are output by the slave unit and the synchronization signals of bits are output by the master unit. If the master unit detects that the parity bit is even, it outputs the $\overline{\text{ACK}}$ signal.

If the parity bit is odd, the master unit judges that the message length bit has not been correctly received, outputs the NACK signal, and returns to the standby status. At this time, the slave unit also returns to the standby status, and communication ends.

(7) Data field

This is data output by the transmission side.

The master unit transmits or receives data to or from a slave unit by using the data field.

The configuration of the data field is shown below.

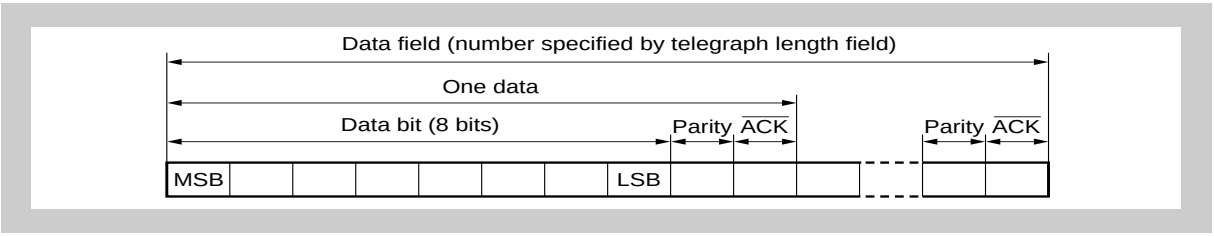

Figure 22-61 Data field

Following the data bit, the parity bit and acknowledge bit are output by the master unit and slave unit, respectively.

Use broadcast communication only when the master unit transmits data. At this time, the acknowledge bit is ignored.

The operation differs as follows depending on whether the master transmits or receives data.

(a) During master transmission

When the master units writes data to a slave unit, the master unit transmits the data bit and parity bit to the slave unit. If the parity is even and the received data is not stored in the IEBBnDR register when the slave unit has received the data bit and parity bit, the slave unit outputs an $\overline{\text{ACK}}$ signal. If the parity is odd or the received data is stored in the IEBBnDR register, the slave unit rejects receiving the data, and outputs the NACK signal.

If the slave unit outputs the NACK signal, the master unit transmits the same data again. This operation continues until the master detects the $\overline{\text{ACK}}$ signal from the slave unit, or the data exceeds the maximum number of transmit bytes.

If there is more data and the maximum number of transmission bytes is not exceeded when the parity is even and when the slave unit outputs the $\overline{\text{ACK}}$ signal, the master unit transmits the next data.

During broadcast communication, the slave unit outputs the NACK signal, and the master unit transfers 1 byte of data at a time. If the parity is odd or the IEBBnDR register is storing received data after the slave unit receives the data bit and parity bit during broadcast communication, the slave unit judges that reception has not been performed correctly, and stops reception.

(b) Master reception

When the master unit reads data from a slave unit, the master unit outputs a sync signal corresponding to all the read bits.

The slave unit outputs the contents of the data and parity bits to the bus in response to the sync signal from the master unit.

The master unit reads the data and parity bits output by the slave unit, and checks the parity.

If the parity is odd or the IEBBnDR register is storing received data, the master unit rejects accepting the data, and outputs the NACK signal. If the maximum number of transmission bytes is within the value that can be transmitted in one communication frame, the master unit rereads the same data.

If the parity is even and the IEBBnDR register is not storing received data, the master unit accepts the data and outputs the $\overline{\text{ACK}}$ signal. If the maximum number of transmission bytes is within the value that can be transmitted in one frame, the master unit reads the next data.

Caution During broadcast communication, do not perform master reception. If you do this, the slave unit cannot be defined and data transfers cannot be performed correctly.

Note that, due to the IEBBn specifications, overrun errors can occur. Therefore, even if reading the IEBBnDR register is late during individual communication and the system has reached the timing for receiving the next data (the overrun status), data can be retransmitted from the master unit by returning a NACK signal, which makes it possible to buy time for reading the IEBBnDR register. However, during broadcast communication, because no $\overline{\text{ACK}}$ signal is output from the slave unit and the master unit ignores $\overline{\text{ACK}}$ signals, even if reading the IEBBnDR register is late, no data is retransmitted from the master. Therefore, for IEBBn, if an overrun occurs during broadcast communication, normal reception is not possible, an overrun error occurs, and an interrupt request (for a communication error) is output.

(8) Parity bit

The parity bit is used to make sure that the transmission data has no error.

The parity bit is appended to each data of the master address, slave address, control, message length, and data bits.

The parity is an even parity. If the number of data bits that are ‘1’ is odd, the parity bit is ‘1’. If the number of data bits that are ‘1’ is even, the parity bit is ‘0’.

(9) Acknowledge bit

During normal communication (communication from one unit to another), an acknowledge bit is appended to the following locations to check whether the data has been correctly received.

- End of slave address field
- End of control field
- End of message length field
- End of data field

The definition of the acknowledge bit is as follows.

0: The transmission data is recognized. ($\overline{\text{ACK}}$ signal)

1: The transmission data is not recognized. (NACK signal)

During broadcast communication, however, the contents of the acknowledge bit are ignored.

(a) Last acknowledge bit of the slave address field

The last acknowledge bit of the slave address field serves as a NACK signal in any of the following cases, and transmission is stopped.

- If the parity of the master address bit or slave address bit is incorrect
- If a timing error (an error in the bit format) occurs
- If a slave unit does not exist

(b) Last acknowledge bit of the control field

The last acknowledge bit of the control field serves as a NACK signal in any of the following cases, and transmission is stopped.

- If the parity of the control bit is incorrect
- If control bit 3 is 1 (write operation) when the slave reception enable flag (the IEBBnBCR.IEBBnSRXE bit) is not set (to 1)

  (For details, see 22.3.2 (1) IEBBnBCR - IEBBn bus control register.)
- If control bit data is read (3H, 7H) when the slave transmission enable flag (the IEBBnBCR.IEBBnSTXE bit) is not set (to 1)

  (For details, see 22.3.2 (1) IEBBnBCR - IEBBn bus control register.)
- If a unit other than one that has set locking requests 3H, 6H, 7H, AH, BH, EH, or FH of the control bit when locking is set
- If the control bit indicates reading of lock addresses (4H, 5H) even when locking is not set
- If a timing error occurs
- If the control bit is undefined

Cautions
1. The $\overline{ACK}$ signal is always returned when the control data of the slave status request is received, if the IEBBnSTXE bit = 0.
2. The NACK signal is returned by the acknowledge bit in the control field when the control data for data/command writing is received, even if the IEBBnSRXE bit = 0.

   Slave reception can be disabled (communication stopped) by the IEBBnSRXE bit only in the case of individual communication. In the case of broadcast communication, communication is maintained and the data interrupt (IEBBTD) or completion interrupt (IEBBTSTA) is generated.

(c) Last acknowledge bit of message length field

The last acknowledge bit of the message length field serves as a NACK signal in any of the following cases, and transmission is stopped.

- If the parity of the message length bit is incorrect
- If a timing error occurs

(d) Last acknowledge bit of the data field

The last acknowledge bit of the data field serves as a NACK signal in any of the following cases, and transmission is stopped.

- If the parity of the data bit is incorrect[a]
- If a timing error occurs after the preceding acknowledge bit has been transmitted
- If the received data is stored in the IEBBnDR register and no more data can be received[a]

a) In this case, when the communication executed is individual communication, if the maximum number of transmit bytes is within the value that can be transmitted in one frame, the transmission side executes transmission of that data field again. For broadcast communication, the transmission side does not execute transmission again, a communication error occurs on the reception side and reception stops.

22.7.7 Transfer data

(1) Slave status

The master unit can learn why the slave unit did not return the $\overline{ACK}$ signal by reading the slave status.

The slave status is determined according to the result of the last communication the slave unit has executed.

All the slave units can supply information on the slave status.

The configuration of the slave status is shown below.

MSB LSB

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Bit 0[a]	Function
0	Transmit data is not written in IEBBnDR register
1	Transmit data is written in IEBBnDR register

Bit 1	Function
0	Receive data is not stored in IEBBnDR register
1	Receive data is stored in IEBBnDR register

Bit 2	Function
0	Unit is not locked
1	Unit is locked

Bit 3	Function
0	Fixed to 0

Bit 4[b]	Function
0	Slave transmission is stopped
1	Slave transmission is ready

Bit 5	Function
0	Fixed to 0

Bit 7	Bit 6	Function	
0	0	Communication mode 0	Indicates the highest communication mode supported by the unit[c].
0	1	Communication mode 1	
1	0	Communication mode 2	
1	1	Not used	

a) After reset: Bit 0 is set to 1.

b) When this module serves as a slave unit, this bit corresponds to the status indicated by IEBBnBCR.IEBBnSTXE bit.

c) Bits 7 and 6 are fixed to “10” because this module can support communication modes 1 and 2.

Figure 22-62 Slave status bit configuration

(2) Lock address

When the lock address is read (control bit: 4H or 5H), the address (12 bits) of the master unit that has issued the lock instruction is configured in 1-byte units as shown below and read.

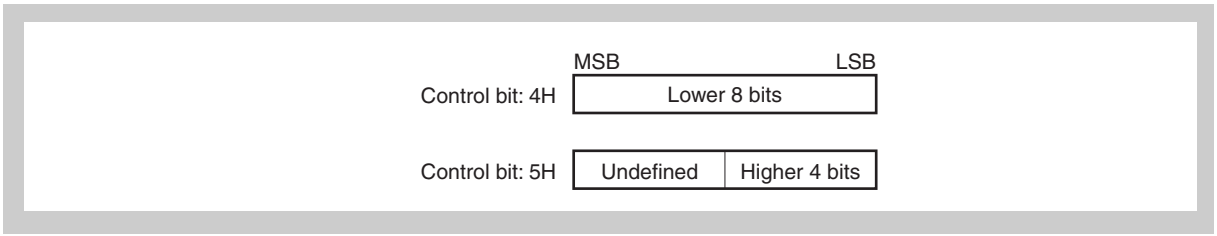

Figure 22-63 Lock address configuration

(3) Data

If the control bit indicates reading of data (3H or 7H), the data in the data buffer of the slave unit is read by the master unit.

If the control bit indicates writing of data (BH or FH), the data received by the slave unit is processed according to the operation rule of that slave unit.

(4) Locking and unlocking

The lock function is used when a message is transferred in two or more communication frames.

The unit that is locked does not receive data from units other than the one that has locked the unit (does not receive broadcast communication).

A unit is locked or unlocked as follows.

(a) Lock setting

If the communication frame is completed without succeeding to transmit or receive data of the number of bytes specified by the message length bit after the message length field has been transmitted or received ($\overline{ACK} = 0$) by the control bit that specifies locking (3H, AH, or BH), the slave unit is locked by the master unit. At this time, the bit (bit 2) in the byte indicating the slave status is set to ‘1’.

(b) Unlocked

After transmitting or receiving data of the number of data bytes specified by the message length bit in one communication frame by the control bit that has specified locking (3H, AH, or BH), or the control bit that has specified unlocking (6H), the slave unit is unlocked by the master unit. At this time, the bit related to locking (bit 2) in the byte indicating the slave status is reset to ‘0’.

Locking or unlocking is not performed during broadcast communication.

Locking and unlocking conditions are shown below.

Table 22-63 Setting conditions:

Control data	Broadcast communication		Individual communication	
	End of communication	End of frame	End of communication	End of frame
3H, 6H[a]	–	–	Cannot be locked	Lock set
AH, BH	Cannot be locked	Cannot be locked	Cannot be locked	Lock set
0H, 4H, 5H, EH, FH	Cannot be locked	Cannot be locked	Cannot be locked	Cannot be locked

a) The frame end of control data 6H (slave status read/unlock) occurs when the parity in the data field is odd, and when the NACK signal from the IEBus unit is repeated with up to the maximum number of transfer bytes being output.

Table 22-64 Unlocking conditions (while locked)

Control data	Broadcast communication from the lock request unit		Individual communication from the lock request unit	
	End of communication	End of frame	End of communication	End of frame
3H, 6H[a]	–	–	Unlocked	Remains locked
AH, BH	Unlocked	Unlocked	Unlocked	Remains locked
0H, 4H, 5H, EH, FH	Remains locked	Remains locked	Remains locked	Remains locked

a) The frame end of control data 6H (slave status read/unlock) occurs when the parity in the data field is odd, and when the NACK signal from the IEBus unit is repeated with up to the maximum number of transfer bytes being output.

22.7.8 Bit format

The format of the bits constituting the communication frame of the IEBus is shown below.

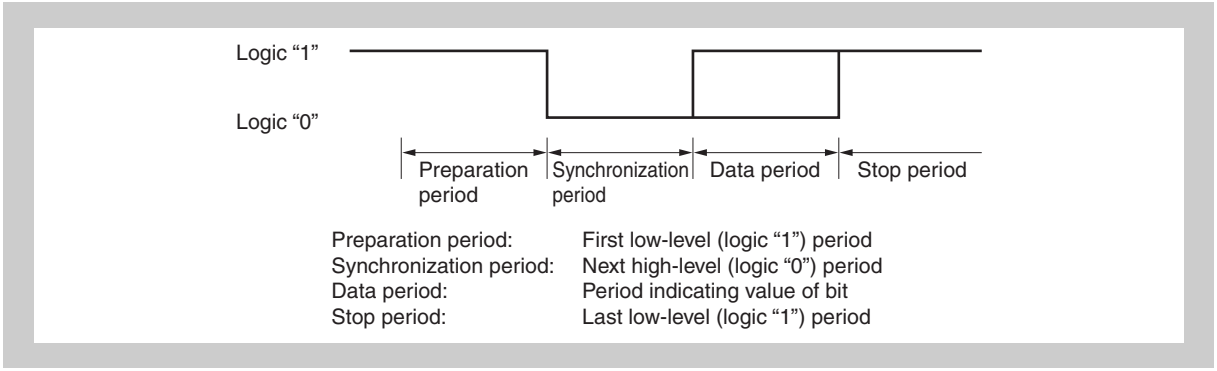

Figure 22-64 IEBus bit format

The synchronization period and data period are almost equal to each other in length.

The IEBus synchronizes each bit. The specifications on the time of the entire bit and the time related to the period allocated to that bit differ depending on the type of transmit bit, or whether the unit is the master unit or a slave unit. The master and slave units monitor whether each period (preparation period, synchronization period, data period, and stop period) is output for the specified time while they are in communication. If a period is not output for the specified time, the master and slave units report a timing error, immediately terminate communication, and enter the standby status.

23.1 Overview

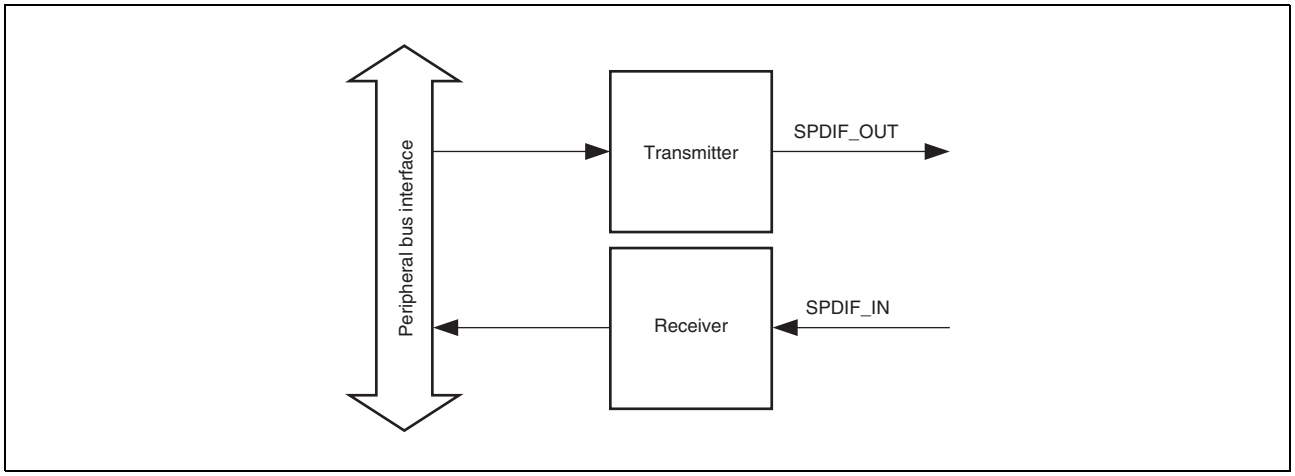

Figure 23.1 Overview Block Diagram

23.2 Features

- Supports the IEC 60958 standard (stereo and consumer use modes only).
- Supports sampling frequencies of 32 kHz, 44.1 kHz, and 48 kHz.
- Supports audio word sizes of 16 to 24 bits per sample.
- Biphase mark encoding.
- Double buffered data.
- Parity encoded serial data.
- Simultaneous transmit and receive
- Receiver autodetects IEC 61937 compressed mode data

23.3 Functional Block Diagram

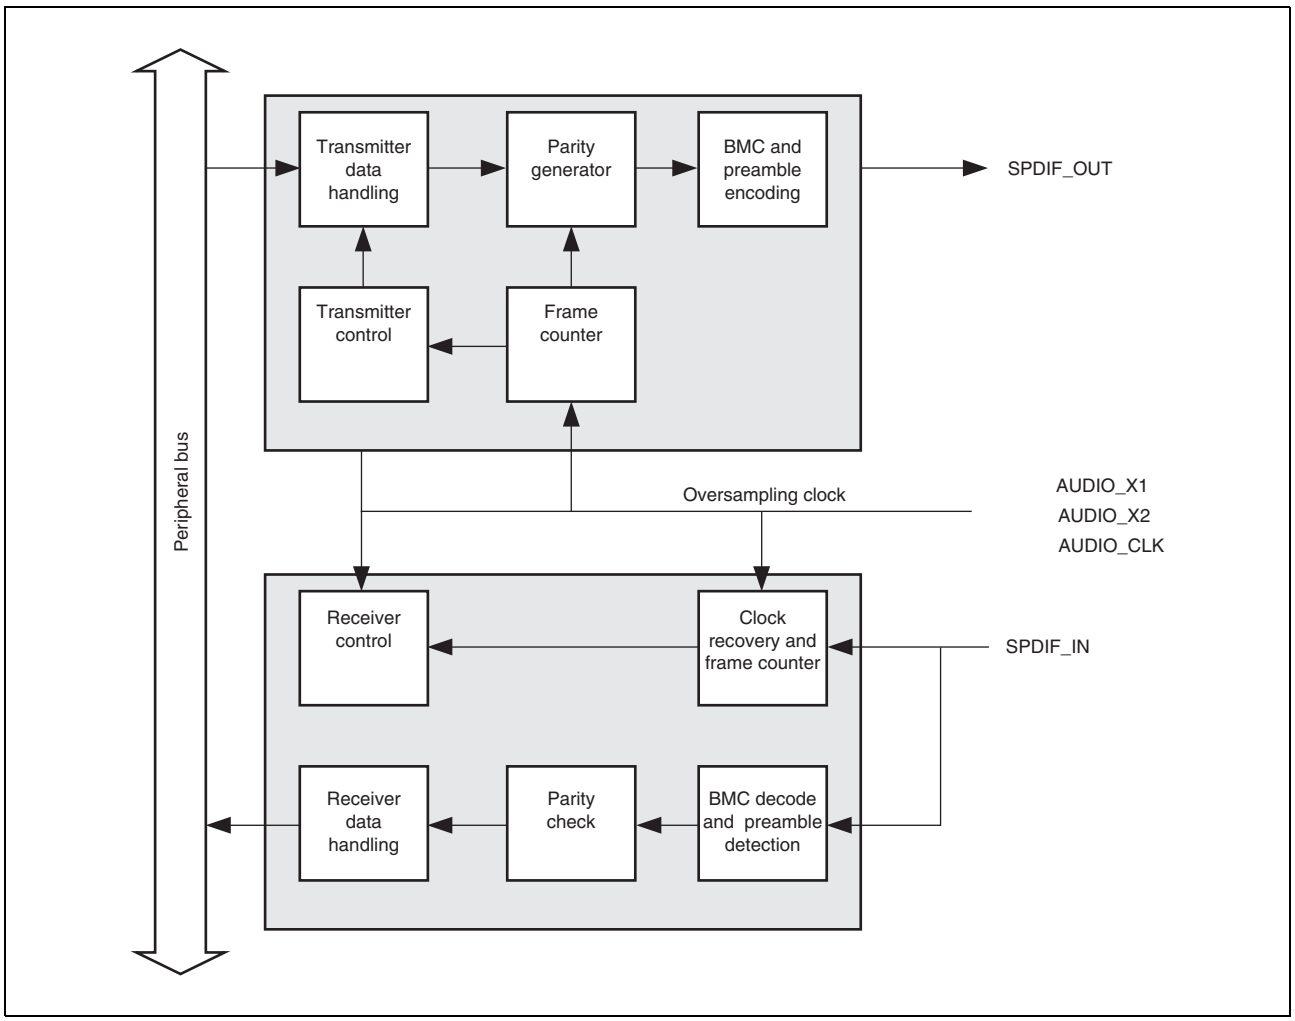

Figure 23.2 Functional Block Diagram

23.4 Input/Output Pins

Table 23.1 shows the pin configuration.

Table 23.1 Pin Configuration

Channel	Pin Name	I/O	Description
0	SPDIF_OUT	Output	Transmitter biphase-mark encoded SPDIF bitstream
1	SPDIF_IN	Input	Receiver biphase-mark encoded SPDIF bitstream
0, 1 (Common)	AUDIO_CLK	Input	External clock for audio
	AUDIO_X1	Input	Crystal resonator/external clock for audio
	AUDIO_X2	Output	

23.5 Renesas SPDIF (IEC60958) Frame Format

The Renesas SPDIF frame consists of two subframes (for channels 1 and 2), each of which contains a 4-bit preamble, audio data of up to 24 bits, a V flag, a user bit, a channel status bit, and an even parity bit. Figure 23.3 shows the subframe format. According to this format, the Renesas SPDIF performs biphase-mark modulation (channel coding) that will make the transmission line's DC component a minimum value.

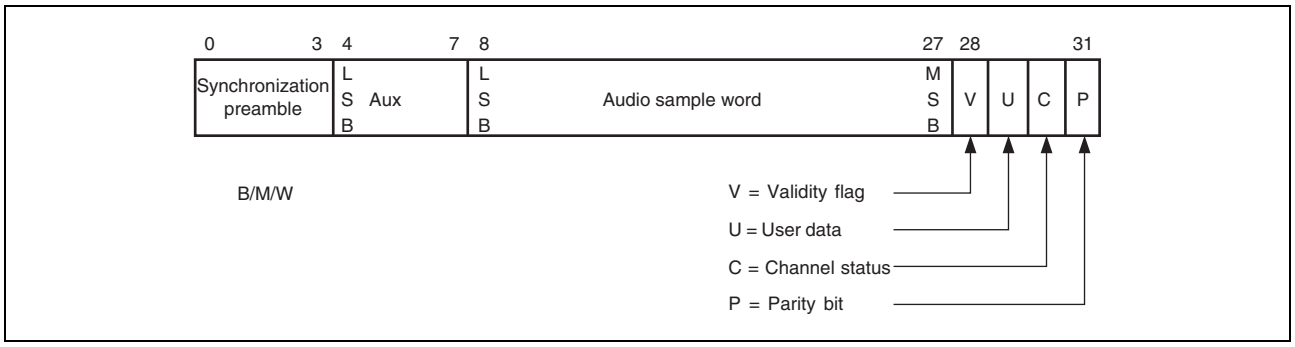

Figure 23.3 Subframe Format

Figure 23.4 shows the block format, which consists of 192 continuous frames. One block begins at the starting frame (preamble B) and ends at the 192nd frame (frame 191), and the preamble is used to identify all subframes. Each block has a total of 384 subframes, which are classified into three categories: subframe 0 indicating the beginning of a new block, subframe 1 (usually the channel 1), and subframe 2 (usually the channel 2). Usually, the music data sent and received by the SPDIF is continuous so that continuous blocks appear.

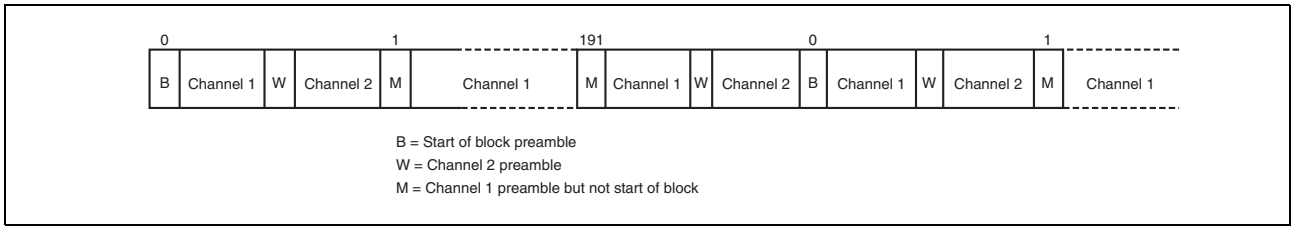

Figure 23.4 Block Format

Table 23.2 shows the binary values of the Renesas SPDIF preambles. The polarity of these preambles differs depending on the status of the preceding symbol (parity bit).

Table 23.2 Binary Preamble Values

Preamble	Preceding Symbol's Status = 0	Preceding Symbol's Status = 1
B	11101000	00010111
M	11100010	00011101
W	11100100	00011011

Note: As shown in Figure 23.3, the even parity bit at time slot 31 of a subframe determines the type of a preamble for one cycle of transmission. Usually, therefore, any one is selected from the set states that are sent through the Renesas SPDIF. However, IEC60958 requires decoding both types in view of connection with the preamble polarity reversed; the Renesas SPDIF has preambles decoded according to Table 23.2.

Channel status information is encoded at the rate of one bit per subframe, making the channel status information per block have a total of 192 bits for each of subframes 1 and 2. For the format of the channel status, refer to the IEC 60958 standard.

23.6 Register

Table 23.3 shows the register configuration.

Table 23.3 Register Configuration

Channel	Register Name	Abbreviation	Address	Access Size
0 (Transmit)	Transmitter channel 1 audio register	TLCA	H'FFFF D800	32
	Transmitter channel 2 audio register	TRCA	H'FFFF D804	32
	Transmitter channel 1 status register	TLCS	H'FFFF D808	32
	Transmitter channel 2 status register	TRCS	H'FFFF D80C	32
	Transmitter user data register	TUI	H'FFFF D810	32
1 (Receive)	Receiver channel 1 audio register	RLCA	H'FFFF D814	32
	Receiver channel 2 audio register	RRCA	H'FFFF D818	32
	Receiver channel 1 status register	RLCS	H'FFFF D81C	32
	Receiver channel 2 status register	RRCS	H'FFFF D820	32
	Receiver user data register	RUI	H'FFFF D824	32
0, 1 (Common)	Control register	CTRL	H'FFFF D828	32
	Status register	STAT	H'FFFF D82C	32
0, 1 (Common)	Transmitter DMA audio data register	TDAD	H'FFFF D830	32
	Receiver DMA audio data register	RDAD	H'FFFF D834	32

Note: All registers are longword registers and must be accessed as such.
A register diagram containing a 0 indicates that the write value should always be 0 (if the register is writeable) and that the read value should always be 0 (if readable).

23.7 Register Descriptions

Legend:

Initial Value: Register value after reset
—: Undefined value
R/W: Readable/writable register. The write value can be read.
R: Read only register. The write value should always be 0.
R/WC0: Readable/writable register. Writing 0 initializes the bit, but writing 1 is ignored.
R/WC1: Readable/writable register. Writing 1 initializes the bit, but writing 0 is ignored.
W: Write only register. Reading is prohibited. If this bit is reserved, the write value should always be 0.
—/W: Write only, Read value undefined

23.7.1 Control Register (CTRL)

Bit:	31	30	29	28	27	26	25	24
	-	-	-	CKS	-	PB	RASS

Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved
28	CKS	0	R/W	Oversampling clock select Selects oversampling clock supply source. 0: AUDIO_X1 1: AUDIO CLK
27	—	0	R	Reserved
26	PB	0	R/W	Pass Back Passes transmitter SPDIF output into SPDIF receiver in SPDIF module. 0: Pass Back disabled 1: Pass Back enabled
25, 24	RASS	All 0	R/W	Receiver Audio Sample Bit Size These bits Indicate the receiver audio sample bit size (16, 20, or 24 bits), for data alignment purposes. 00: 16-bit sample 01: 20-bit sample 10: 24-bit sample 11: Reserved

Bit	Bit Name	Initial Value	R/W	Description
23, 22	TASS	All 0	R/W	Transmitter Audio Sample Bit Size These bits Indicate the transmitter audio sample bit size (16, 20, or 24 bits), for data alignment purposes. 00: 16-bit sample 01: 20-bit sample 10: 24-bit sample 11: Reserved
21	RDE	0	R/W	Receiver DMA Enable Enables DMA requests for the receiver. 0: Receiver DMA disabled 1: Receiver DMA enabled
20	TDE	0	R/W	Transmitter DMA Enable Enables the DMA requests for the transmitter. 0: Transmitter DMA disabled 1: Transmitter DMA enabled
19	NCSI	0	R/W	New Channel Status Information Set this bit to 1 when new channel status information to be corrected is in the transmitter. 0: New channel status information has not been in transmitter 1: New channel status information has been in transmitter
18	AOS	0	R/W	Audio Only Samples Clear this bit to 0 when audio channel 1 and channel 2 registers contain user information. When this bit is set to 1, all user bits are cleared to 0. 0: User information present 1: User information not present
17	RME	0	R/W	Receiver Module Enable Enables the receiver module. 0: Receiver module disabled 1: Receiver module enabled
16	TME	0	R/W	Transmitter Module Enable Enables the transmitter module. 0: Transmitter module disabled 1: Transmitter module enabled
15	REIE	0	R/W	Receiver Error Interrupt Enable Enables the receiver error interrupts. 0: Receiver error interrupt disabled 1: Receiver error interrupt enabled
14	TEIE	0	R/W	Transmitter Error Interrupt Enable Enables the transmitter error interrupts. 0: Transmitter error interrupt disabled 1: Transmitter error interrupt enabled
13	UBOI	0	R/W	User Buffer Overrun Interrupt Enable Enables the user buffer overrun interrupts. 0: User buffer overrun interrupt disabled 1: User buffer overrun interrupt enabled
12	UBUI	0	R/W	User Buffer Underrun Interrupt Enable Enables the user buffer underrun interrupts. 0: User buffer underrun interrupt disabled 1: User buffer underrun interrupt enabled
11	CREI	0	R/W	Clock Recovery Error Interrupt Enable Enables the clock recovery error interrupts. 0: Clock recovery error interrupt disabled 1: Clock recovery error interrupt enabled
10	PAEI	0	R/W	Parity Error Interrupt Enable Enables the parity check error interrupts. 0: Parity check error interrupt disabled 1: Parity check error interrupt enabled

Bit	Bit Name	Initial Value	R/W	Description
9	PREI	0	R/W	Preamble Error Interrupt Enable Enables the preamble check error interrupts. 0: Preamble error interrupt disabled 1: Preamble error interrupt enabled
8	CSEI	0	R/W	Channel Status Error Interrupt Enable Enables the channel status error interrupts. 0: Channel status error interrupt disabled 1: Channel status error interrupt enabled
7	ABOI	0	R/W	Audio Buffer Overrun Interrupt Enable Enables the receiver audio buffer overrun interrupts. 0: Audio buffer overrun interrupt disabled 1: Audio buffer overrun interrupt enabled
6	ABUI	0	R/W	Audio Buffer Underrun Interrupt Enable Enables the transmitter audio buffer underrun interrupts. 0: Audio buffer underrun interrupt disabled 1: Audio buffer underrun interrupt enabled
5	RUII	0	R/W	Receiver User Information Interrupt Enable Enables the receiver user information register full interrupts. 0: Receiver user information interrupt disabled 1: Receiver user information interrupt enabled
4	TUII	0	R/W	Transmitter User Information Interrupt Enable Enables the transmitter user information register empty interrupts. 0: Transmitter user information interrupt disabled 1: Transmitter user information interrupt enabled
3	RCSI	0	R/W	Receiver Channel Status Interrupt Enable Enables the receiver channel status register full interrupts. 0: Receiver channel status interrupt disabled 1: Receiver channel status interrupt enabled
2	RCBI	0	R/W	Receiver Channel Buffer Interrupt Enable Enables the receiver audio channel buffer full interrupts. 0: Receiver audio channel interrupt disabled 1: Receiver audio channel interrupt enabled
1	TCSI	0	R/W	Transmitter Channel Status Interrupt Enable Enables the transmitter channel status register empty interrupts. 0: Transmitter channel status interrupt disabled 1: Transmitter channel status interrupt enabled
0	TCBI	0	R/W	Transmitter Channel Buffer Interrupt Enable Enables the transmitter audio channel buffer empty interrupts. 0: Transmitter audio channel interrupt disabled 1: Transmitter audio channel interrupt enabled

23.7.2 Status Register (STAT)

Bit:	31	30	29	28	27	26	25	24
	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	CMD
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8
	RIS	TIS	UBO	UBU	CE	PARE	PREE	CSE
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0

Bit:	7	6	5	4	3	2	1	0
	ABO	ABU	RUIR	TUIR	CSRX	CBRX	CSTX	CBTX
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/WC0	R/WC0	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved
16	CMD	0	R	Compressed Mode Data Sets if the data being received is compressed mode data (When bit 1 = 1 in the V flag and channel status). 0: Data is not in compressed mode 1: Data is in compressed mode
15	RIS	1	R	Receiver Idle State Sets if the receiver is in the idle state. 0: Receiver is not in idle state 1: Receiver in idle state
14	TIS	1	R	Transmitter Idle State Sets if the transmitter is in the idle state. 0: Transmitter is not in idle state 1: Transmitter is in idle state
13	UBO	0	R/WC0	User Buffer Overrun* Sets if the receiver user buffer overruns. This bit is cleared by writing 0 to the register. If bit REIE and bit UBOI in the control register are set this causes an interrupt. 0: User buffer has not overrun 1: User buffer has overrun
12	UBU	0	R/WC0	User Buffer Underrun* Sets if the transmitter user buffer underrun. This bit is cleared by writing 0. If bits TEIE and UBUI in the control register are set this causes an interrupt. 0: User buffer has not underrun 1: User buffer has underrun
11	CE	0	R/WC0	Clock Error* Sets when the clock recovery falls out of synchronization. This bit is cleared by writing 0. If bits REIE and CREI in the control register are set this causes an interrupt. 0: Clock recovery stable 1: Clock recovery error
10	PARE	0	R/WC0	Parity Error* Sets when the parity checker produces a fail result. This bit is cleared by writing 0. If bits REIE and PAEI in the control register are set this causes an interrupt. 0: Parity check correct 1: Parity error

Bit	Bit Name	Initial Value	R/W	Description
9	PREE	0	R/WC0	Preamble Error* Sets when the start of word preamble fails to appear in the correct place. This bit is cleared by writing 0. If bits REIE and PREI in the control register are set this causes an interrupt. Note: Only set after a start of block preamble has occurred. 0: Preamble is in the correct place 1: Preamble error
8	CSE	0	R/WC0	Channel Status Error*1 Sets when the channel status information is written before the 32nd frame of the current block. This bit is cleared by writing 0. If bits TEIE and CSEI in the control register are set this causes an interrupt. 0: Channel status correct 1: Channel status error
7	ABO	0	R/WC0	Audio Buffer Overrun*1 Indicates that the receiver audio buffer is full in both the first and second stages and that data has been overwritten. This bit is cleared by writing 0. If bits REIE and ABOI in the control register are set then this causes an interrupt. 0: Receiver audio buffer has not overrun 1: Receiver audio buffer has overrun
6	ABU	0	R/WC0	Audio Buffer Underrun*1 Indicates that the transmitter audio buffer is empty in both the first and second stages and that the last data transmission has been repeated. This bit is cleared by writing 0. If bits TEIE and ABUI in the control register are set then this causes an interrupt. 0: Transmitter audio buffer has not underrun 1: Transmitter audio buffer has underrun
5	RUIR	0	R	Receiver User Information Register Status Indicates the status of the receiver user information register. This bit is cleared by reading from the receiver user register. If bit RUII in the control register is set then this causes an interrupt. 0: Receiver user information register is empty 1: Receiver user information register is full
4	TUIR	0	R	Transmitter User Information Register Status Indicates the status of the transmitter user information register. This bit is cleared by writing to the transmitter user register. If bit TUII in the control register is set then this causes an interrupt. 0: Transmitter user information register is full 1: Transmitter user information register is empty
3	CSRX	0	R	Channel 1 and Channel 2 Status for Receiver Indicates the status of the receiver channel status registers. This bit is cleared by reading from the receiver channel status registers. If bit RCSI in the control register is set this causes an interrupt. 0: Receiver channel status registers are empty 1: Receiver channel status registers are full
2	CBRX	0	R	Channel 1 and Channel 2 Buffers for Receiver Indicates the status of the receiver audio channel registers. This bit is cleared by reading from the receiver audio channel registers. If bit RCBI in the control register is set this causes an interrupt. 0: Receiver audio channel registers are empty 1: Receiver audio channel registers are full
1	CSTX	0	R	Channel 1 and Channel 2 Status for Transmitter Indicates the status of the transmitter channel status registers. This bit is cleared by writing to the transmitter channel status registers. If bit TCSI in the control register is set this causes an interrupt. 0: Transmitter channel status register is full 1: Transmitter channel status register is empty

Bit	Bit Name	Initial Value	R/W	Description
0	CBTX	0	R	Channel 1 and Channel 2 Buffers for Transmitter Indicates the status of the transmitter audio channel registers. This bit is cleared by writing to the transmitter audio channel registers. If bit TCBI in the control register is set this causes an interrupt. 0: Transmitter audio channel registers are full 1: Transmitter audio channel registers are empty

Note 1. When an error bit is detected during DMA transfer, DMA transfer settings must be made again. In this case, the Renesas SPDIF's module enable bit (either the RME or TME bit) and the DMA enable bit (either the RDE or TDE bit) must be disabled and the error status must be cleared before making DMA transfer settings again. Then the module enable bit should be set and DMA transfer can be started again.

23.7.3 Transmitter Channel 1 Audio Register (TLCA)

Bit:	31	30	29	28	27	26	25	24

R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	—	W	Reserved
23 to 0	Audio PCM Data	All 0	W	Audio PCM Data LSB aligned PCM encoded audio data.

23.7.6 Transmitter User Data Register (TUI)

U-bit data in subframes is written in to this register. Because U-bit data is transmitted in a sequence of subframes 1 and 2, you need to update the data on a 16-frame basis. For the contents of the user bytes refer to the appropriate standard for the device in use. The user bits to be transmitted are set in sequence starting at the LSB.

Bit:	31	30	29	28	27	26	25	24
	User Byte 4							
Initial value:	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W

Bit:	23	22	21	20	19	18	17	16
	User Byte 3

R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	User Byte 4	All 0	W	U-bit information is stored here.
23 to 16	User Byte 3	All 0	W	
15 to 8	User Byte 2	All 0	W	
7 to 0	User Byte 1	All 0	W	

23.7.7 Transmitter Channel 1 Status Register (TLCS)

The 30-bit register stores the channel status information to be transmitted. For each channel, channel status information per frame consists of 192 bits. Because necessary data covers only the 30 bits that are set in the following register, zeros continue to be sent after the transmission of the first 30 bits.

Bit:	31	30	29	28	27	26	25	24
	-	-	CLAC[1:0]		FS[3:0]			
Initial value:	-	-	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W

19 to 16	SRCNO[3:0]	All 0	W	Source Number 0000: Don't care 0001: 1 0010: 2 0011: 3
15 to 8	CATCD[7:0]	All 0	W	Category Code (Example) 00000000: 2-channel general format 00000001: 2-channel compact disc (IEC 908) 00000010: 2-channel PCM encoder/decoder 00000011: 2-channel digital audio tape recorder
7, 6	—	All 0	W	Reserved The write value should always be 0.
5 to 1	CTL[4:0]	All 0	W	Control The control bits are copied from the source (see IEC60958 standard).
0	—	0	W	Reserved The write value should always be 0.

23.7.8 Transmitter Channel 2 Status Register (TRCS)

The 30-bit register stores the channel status information to be transmitted. For each channel, channel status information per frame consists of 192 bits. Because necessary data covers only the 30 bits that are set in the following register, zeros continue to be sent after the transmission of the first 30 bits.

Bit:	31	30	29	28	27	26	25	24

23.8 Functional Description—Transmitter

23.8.1 Transmitter Module

The transmitter module transmits PCM data and auxiliary information after encoding it according to the method of biphase-mark modulation that complies with the IEC60958 standard (SPDIF).
The clock for the transmitter module is an oversampling clock supplied from the outside. This clock usually selects a value that serves as an oversample at a frequency eight times larger than the clock frequency required for biphase-mark encoding. In this case, the clock frequency required to transmit 32 time slots in a subframe is 512 times as large as the sample frequency for audio data.
Audio data and channel status information are first written into the module's channel 1 and then into channel 2. Generally, the channel status need to be written only when the information changes. The SPDIF module requests that the channel status be written in 30 frames -- when all the current channel status data have been transmitted. You need to write somewhere between frame 31 and the beginning of the next block of 192 frames.
The audio data is stored in a double buffer arrangement. To make sure that the first stage buffer is empty, you can send an interrupt request or poll the status register. DMA transfers send channel 1 audio data on the first request and channel 2 data on the second.
The channel status information is stored in the 30-bit registers of channels 1 and 2. For each channel, the channel status information per frame consists of 192 bits. Because necessary data covers only 30 bits, zeros continue to be sent after the transmission of the first 30 bits until the block is completed.
User data forms a 32-bit double buffer arrangement. You can make sure that the first stage buffer is empty by either sending an interrupt request or polling the status register. Usually, information about the user data will become insufficient with the length of data between blocks. Transmission takes place in a sequence of channels 1 and 2. For the user data within a block, 384 bits are transmitted before the next block is continuously transmitted.
The audio data handled by the Renesas SPDIF module is a linear PCM, making it possible to set up to 24 bits. For this reason, the V flag indicating that audio data is a linear PCM remains to be 0. The V flag involves no register-based setting. An even parity is created for each 32 bits of serial output data (excluding the preamble).

Note: • When transmitter user buffer underrun occurs, the current data in the buffer data of SPDIF is transmitted until the next data is filled.

23.8.2 Transmitter Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state when 0 is written to the TME bit in the CTRL register. When the transmitter module is idle, it has the following settings:

- The transmitter idle status bit (TIS) is set to 1, all other status bits are cleared to 0.
- Preamble generation is invalid.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both word_count and frame_count are set to 0.
- The output from the biphase-mark encoder is set to 0.

Channel status, user and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the TME bit in the CTRL register.

23.8.3 Initial Settings for Transmitter Module

When the TME bit is set to 1, the TUIR and CSTX bits are set to 1. After that, if data is written in the order of 1) TUI and 2) TLCS and TRCS, a channel status error will occur. To avoid this, be sure to write data in the order of 1) TLCS and TRCS and 2) TUI.
Before writing the first audio data (write access to TLCA or TRCA by the CPU or write access to TDAD by the DMA transfer) after setting the TME bit to 1, be sure to check that the CSTX and TUIR bits are cleared by writing to TLCS, TRCS, and TUI.

23.8.4 Transmitter Module Data Transfer

Once the transmitter module has left the idle state, it is ready for data transfer. Data transfer timing can be achieved in three ways. Either the transfer is done by interrupts, DMA requests or by polling the status register. There is a shared interrupt line (for both transmit and receive) and a single transmitter DMA request line.
Figure 23.5 shows a data transfer with an interrupt for the transmitter.

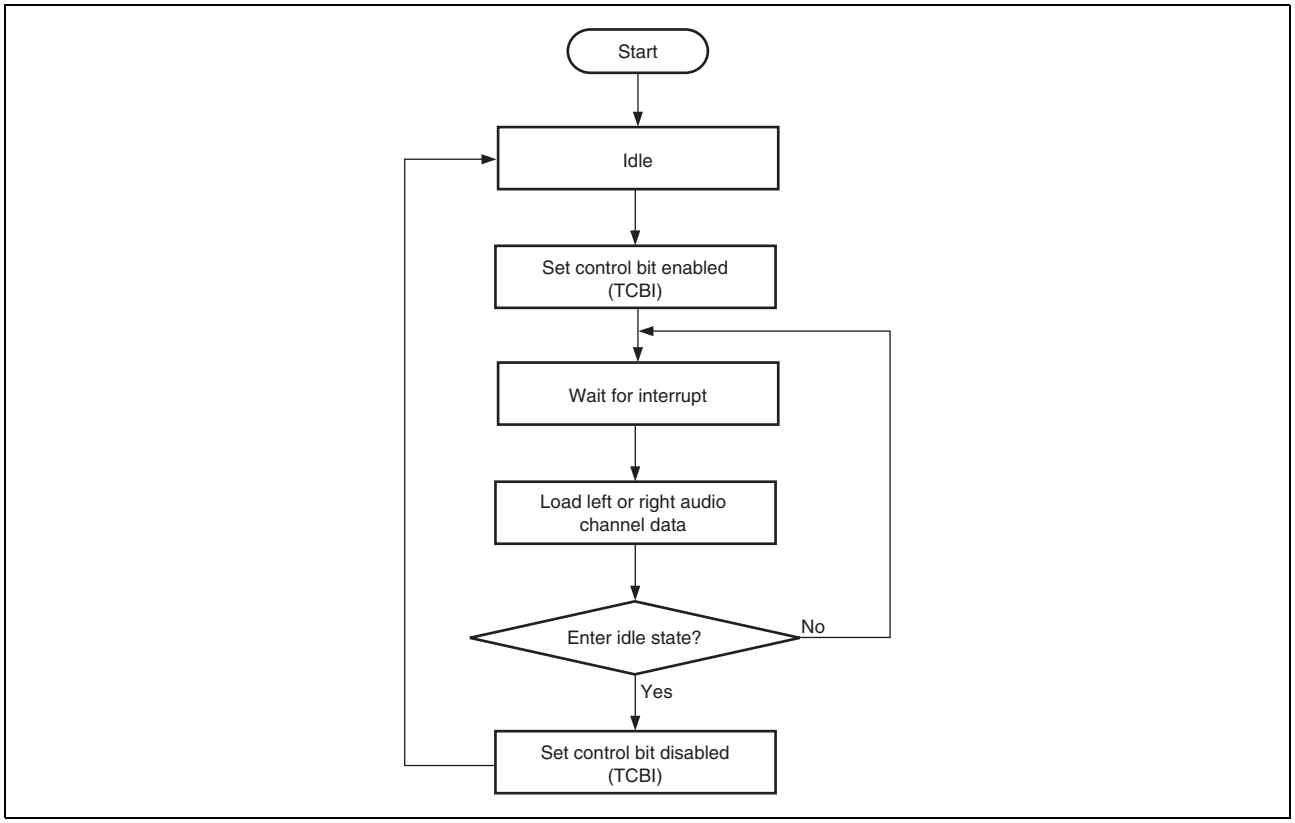

Figure 23.5 Transmitter Data Transfer Flow Diagram - Interrupt Driven

Figure 23.6 shows a data transfer with a DMA transfer for the transmitter.

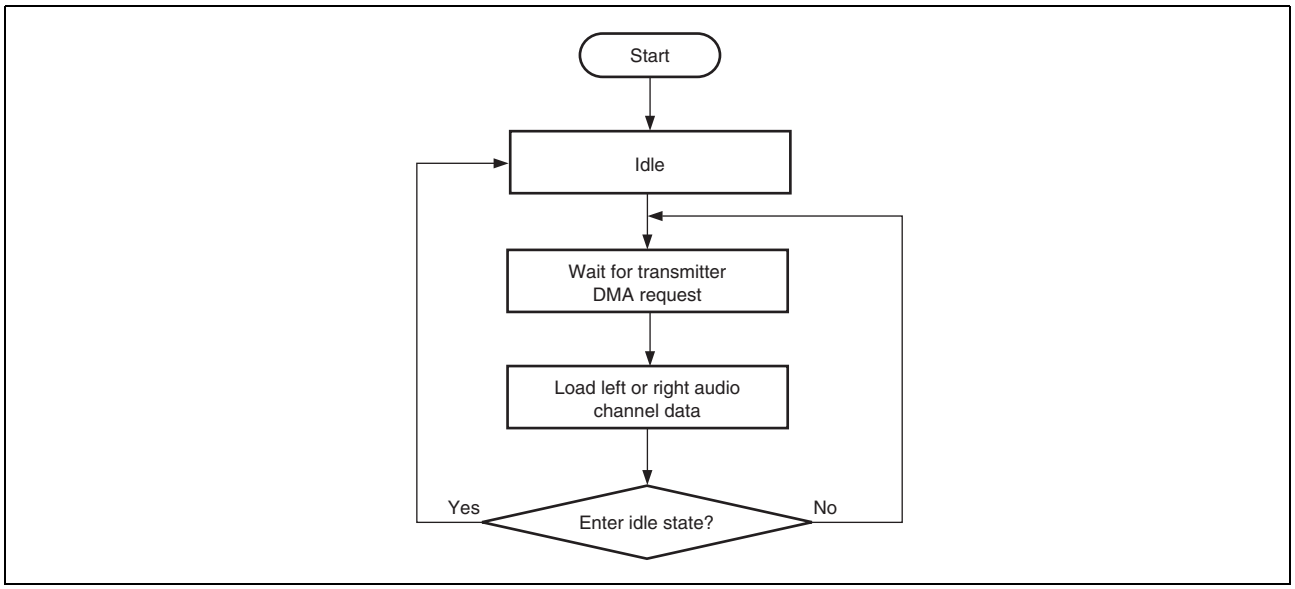

Figure 23.6 Transmitter Data Transfer Flow Diagram—DMA Request Driven

Channel status information is required to be updated when the information has changed. Because the updating needs to be done before the transmission of the next block, the channel status to be updated should be written after 30 frames have been sent; this is indicated either by an interrupt or by polling the status bit. If channel status is written before 30 frames have been sent (while current information is being sent) then an interrupt indicates that the channel status error bit (CSE) in the status register has been set.

Note: • 30 frames contains all the valid information in a single channel status block.

23.9 Functional Description—Receiver

23.9.1 Receiver Module

The receiver module demodulates data and clock signals from the input encoded according to the IEC60958 standard. The encoded data, shown in linear PCM format, is stored into the audio data register. The register also stores the channel status and user information being received simultaneously as auxiliary information.
The main clock for the receiver module is an oversampling clock supplied from the outside. The module operates at a frequency four times as large as the oversampling clock.

Note: • The oversampling clock is the same for the transmitter and receiver.

Clock recovery is performed using a pulse width counter and averaging filters to produce a sampling pulse in the middle of each bit in the datastream. A clock error status bit indicates clock synchronization loss. Synchronization is achieved when a preamble occurs on the data stream for the first time. Continuous adjustment prevents jitter and/or clock drift from affecting clock recovery, provided that they fall within the clock recovery specifications.
Once the clock recovery is successful the biphase-mark decoder initiates its preamble detection. The decoder searches for the start of block preamble (see Table 23.2). A preamble error status bit indicates that following preambles have not appeared at the correct time, such failures are most likely caused by transmission loss or interference.
Even parity checking is performed on the decoded data. A discrepancy will result in the parity error status bit being set.
The SPDIF module acquires user data and channel status information in addition to audio data. The audio is stored in a double buffer arrangement. Either an interrupt request because of a full buffer or polling of the status bit will indicate when the data is ready to be read. DMA transfers receive channel 1 audio data on the first request and channel 2 data on the second.
Channel status is stored in a 30-bit register. Channel status information is received at 1-bit per subframe. Therefore the registers will not be full until a total of 30 frames for each channel have been received. New channel status is compared with the current data to see if it has changed and is only read by the processor if it has. User data, which is also received at the same time, is stored into the register on a subframe basis, so that the reception is completed when 16 frames are reached.

Note 1. Channel status data requests do not support DMA.
Note 2. When receiver user buffer overrun occurs, the current data in the buffer data of SPDIF is overwritten by the next incoming data from SPDIF interface.

23.9.2 Receiver Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state by writing 0 to bit RME in the CTRL register. Whilst idle the module has the following settings:

- The receiver idle status bit is set to 1, all other status bits are cleared to 0.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both Word_count and frame_count are set to 0.

Channel status registers, user data registers and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the bit RME in the CTRL register.

23.9.3 Receiver Module Data Transfer

Once the module has left the idle state it is ready for data transfer. Data transfer timing can be achieved in three ways. The transfer can be done by interrupts, or by polling the status register, or by DMA. There is a shared interrupt line (transmit and receive) and a single receiver DMA request line. Data transfer for the receiver can be interrupted by error signals caused by:

1. Clock recovery failure.
2. Transmission loss or interference – indicated by a preamble error.
3. Parity check failure.

Transmission loss or interference can cause the start of subframe or start of block preamble to be misplaced or not present.
Parity check failure occurs when the parity bit is incorrect, this can be caused by any of the above.

- Clock Recovery Deviation
  The receive margin for clock recovery is based on the following equation:

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)\, F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

where M = receive margin
N = oversampling rate
L = frame length = 33
D = duty cycle = 0.6
F = oversampling clock deviation = Level II accuracy = 1000 in $10e^{-6}$

Figure 23.7 indicates what the receive margin M represents.

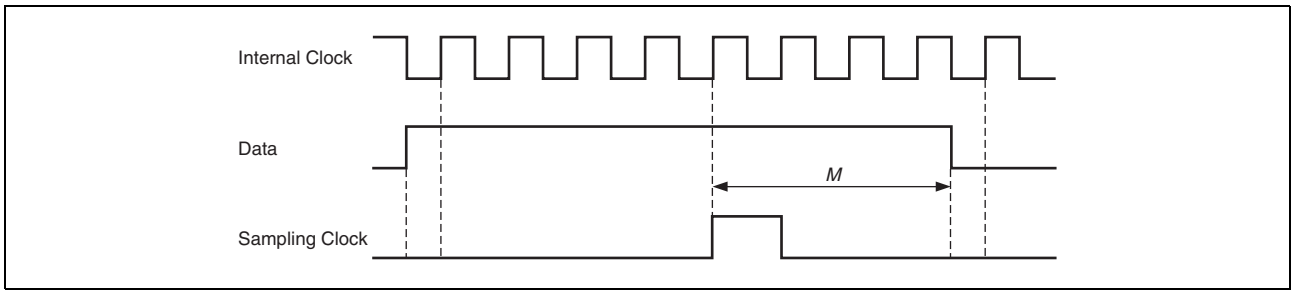

Figure 23.7 Receive Margin

Introducing jitter into the equation gives the following inequality.

$$j \leq \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)\, F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

J = clock jitter
Eight times oversampling produces a receive margin = 39.25%
Four times oversampling produces a receive margin = 31.75%
Two times oversampling produces a receive margin = 16.75%

The fastest sample frequency is 48 kHz. This requires a clock speed of 128 × 48 kHz = 6.144 MHz. The worst case jitter in one cycle is specified at 40 ns = 24.5% of the period. This means that an oversampling rate of 4 or more will satisfy the inequality and therefore be sufficient for clock recovery.

Figure 23.8 illustrates the receiver data transfer using interrupts.

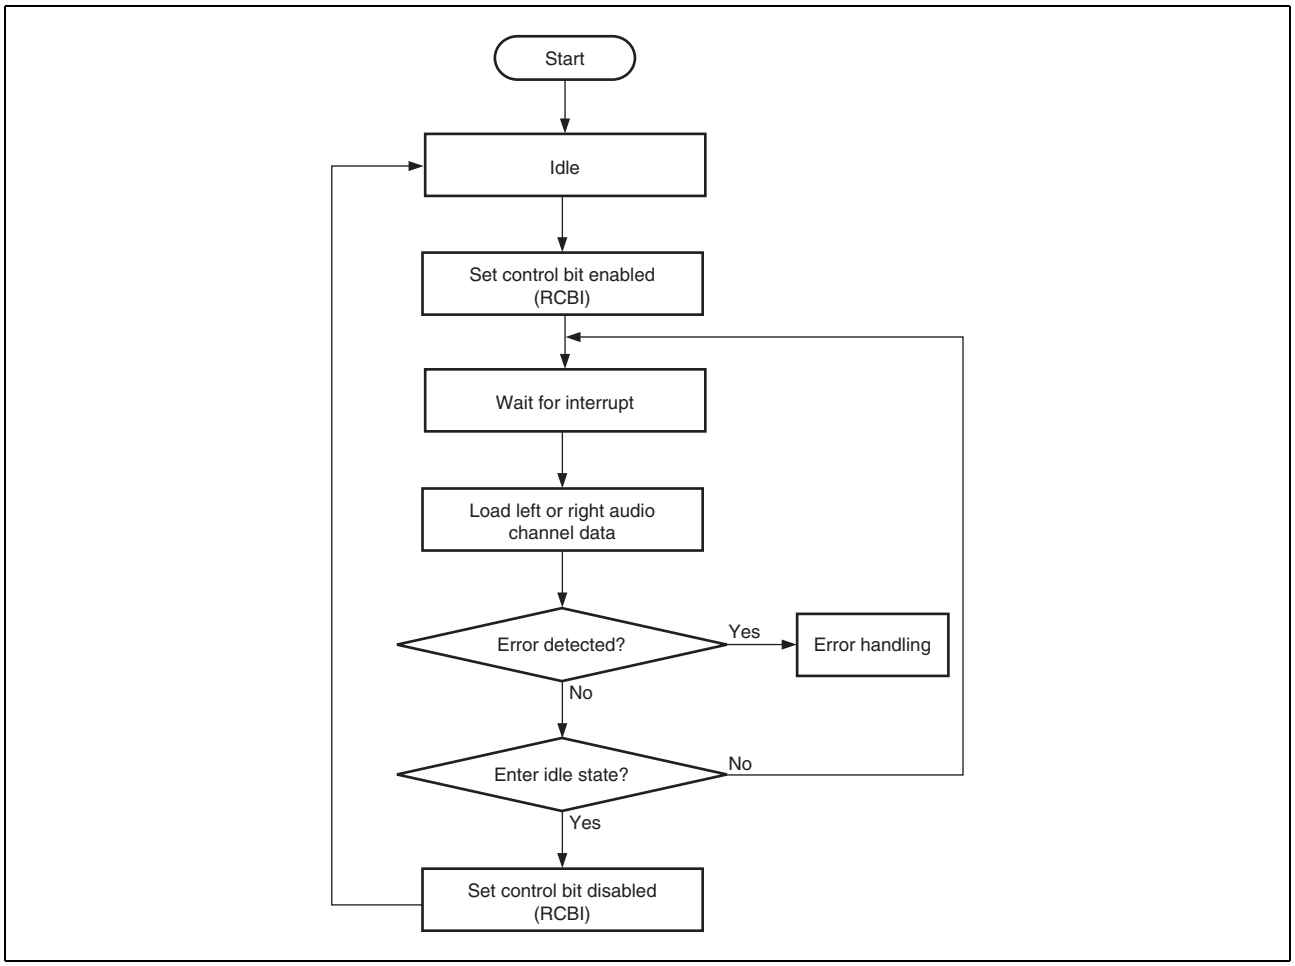

Figure 23.8 Receiver Data Transfer Flow Diagram - Interrupt Driven

Interrupts to indicate that the channel status information register is full occur after frame 30 has been received and only if the information has changed. When the first four bytes have been stored an interrupt occurs.

23.10 Disabling the Module

23.10.1 Transmitter and Receiver Idle

The transmitter or receiver modules can be disabled by writing 0 to the idle bit in the control register (TME for the transmitter and RME for the receiver). The idle state can be detected by polling the idle bit in the status register (TIS and RIS).

23.11 Compressed Mode Data

Compressed mode data is defined in the IEC 61937 specification. This module only detects compressed mode data. This is done by checking the parity flag (V flag) and bit 1 in the channel status data. If both are one then the data is in compressed mode. This is indicated by the setting of the CMD bit in the status register.

Note: • Only the receiver detects compressed mode data since the information is not relevant to the transmitter.

23.13 Usage Notes

23.13.1 Clearing TUIR

After TUI is written to, the TUIR bit is cleared only after transmission of a maximum of one frame is completed. When using a transmitter user information interrupt to write data to TUI, check that the TUIR bit is cleared before terminating the interrupt handling routine so that the interrupt is not unexpectedly accepted again.

23.13.2 Frequency of Clock Input for Audio

The frequency of the clock input to the AUDIO_X1 and AUDIO_X2 or AUDIO_CLK must be lower than the Bϕ frequency.

24. CD-ROM Decoder

This module is only incorporated in the RZ/A1L.

The CD-ROM decoder decodes streams of data transferred from the CD-DSP. When the medium is CD-DA*1, the data stream is not input to the CD-ROM decoder because it consists of PCM data. In the case of CD-ROM*2, the stream of data is input and the CD-ROM decoder performs sync code detection and maintenance, descrambling, ECC correction, and EDC checking, and outputs the resulting stream of data.

However, since the stream received by the CD-ROM decoder is assumed to consist of data from a CD-ROM transferred via the serial sound interface, the decoder does not bother with the subcodes defined in the CD-DA standard.

Note 1. Compliant with JIS S 8605 (Red Book)

Note 2. Compliant with JIS X 6281 (Yellow Book)

24.1 Features

- Sync-code detection and maintenance
  Detects sync codes from the CD-ROM and is capable of providing sync-code maintenance (automatic interpolation of sync codes) when the sync code cannot be detected because of defects such as scratches on the disc.
  Five sector-synchronization modes are supported: automatic sync maintenance mode, external sync mode, interpolated sync mode, and interpolated sync plus external sync mode.
- Descrambling
- ECC correction
  P-parity-based correction, Q-parity-based correction, PQ correction, and QP correction are available.
  PQ correction and QP correction can be applied repeatedly up to three times. This, however, depends on the speed of the CD. For example, three iterations are possible when the CD-ROM decoder is operating at 60 MHz with a double-speed CD drive.
  Two buffers are provided due to the need for ECC correction. This allows parallel operation, where ECC correction is performed in one buffer while the data stream is being received in the other.
- EDC checking
  The EDC is checked before and after ECC correction. An operating mode is available in which, if the result of pre-ECC correction EDC checking indicates no errors, ECC correction is not performed regardless of the result of syndrome calculation.
- Data buffering control
  The CD-ROM decoder outputs data to the buffer area in a specific format where the sync code is at the head of the data for each sector.

24.1.1 Formats Supported by CD-ROM Decoder

This module supports the five formats shown in Figure 24.1.

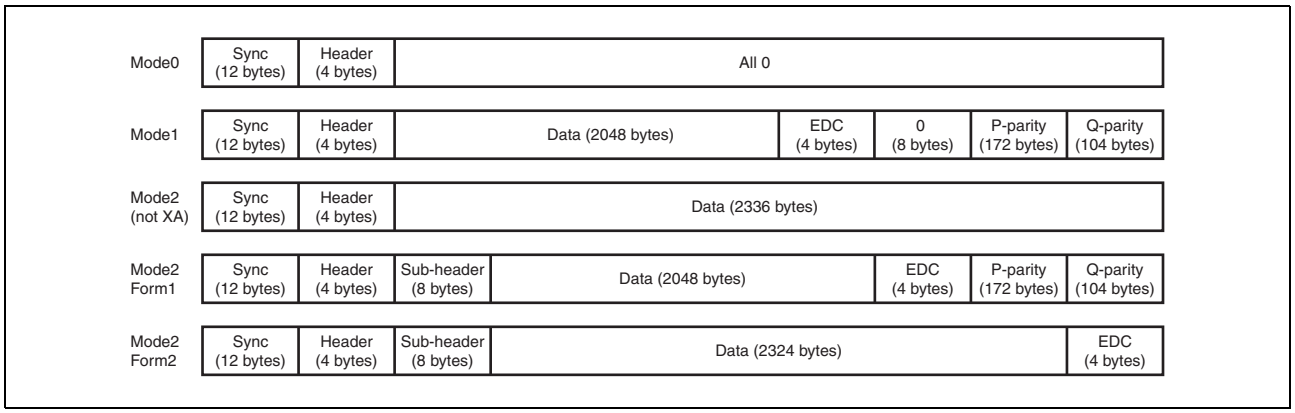

Figure 24.1 Formats Supported by CD-ROM Decoder

24.2 Block Diagrams

Figure 24.2 is a block diagram of the CD-ROM decoder functions of this LSI and the bus bridge for connection to the bus, that is, of the elements required to implement the CD-ROM decoder function.

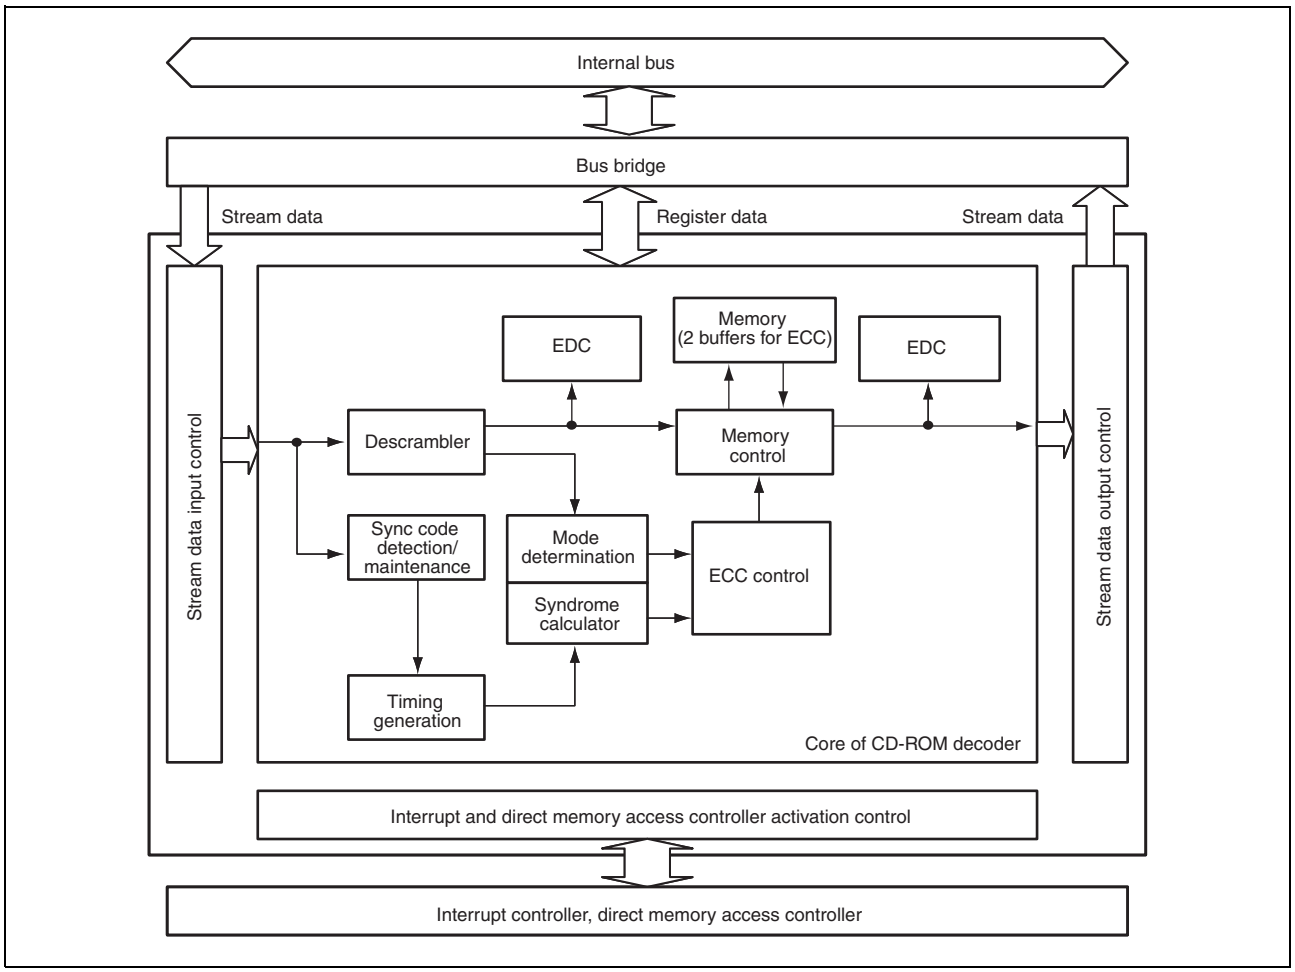

Figure 24.2 Block Diagram

The core of the CD-ROM decoder executes a series of processing required for CD-ROM decoding, including descrambling, sync code detection, ECC correction (P- and Q-parity-based correction), and EDC checking. The core includes sufficient memory to hold two sectors of data.
Input data come from the internal bus and output data go out via the internal bus along a single line each, but the bus bridge logic sets up branches for the register access port and stream data port.
The stream data from the CD-DSP are transferred via the serial sound interface to the stream data input control block. They are then subjected to descrambling, ECC correction, and EDC checking as they pass through the CD-ROM decoder. After these processes, data from one sector are obtained. The data are subsequently transferred to the stream-data buffer via the stream-data output control block. Stream data can be transferred by either the direct memory access controller or the CPU.
Figure 24.3 is a block diagram of the bus-bridge logic.
Since the input stream is transferred over the serial sound interface, transfer is relatively slow. On the other hand, data from the output stream can be transferred at high speeds because they are already in the core of the CD-ROM decoder. Since the data for output are buffered in SDRAM or other memory, they must be transferred at high speeds in order to reduce the busy rate of the SDRAM. For this reason, the data for the output stream are read out before the CD-ROM decoder receives an output stream data read request from the internal bus. This allows the accumulation of streaming data in the registers of the bus bridge, so that the data are ready for immediate output to the internal bus upon a request from the internal bus. Accordingly, the reception of a request to read from registers other than the stream-data registers after the stream data has already been read out and stored in the register of the bus bridge is possible. To cope with this, the CD-ROM decoder is provided with separate intermediary registers for the output stream-data register and the other registers.

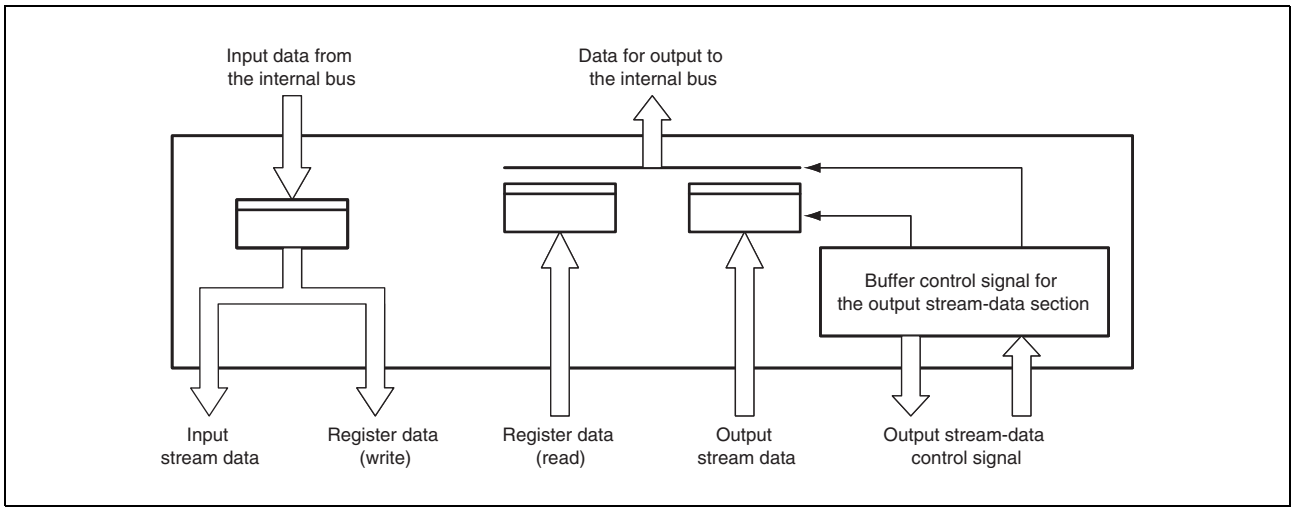

Figure 24.3 Schematic Diagram of the Bus Bridge

Figure 24.4 is a schematic diagram of the stream-data input control block. The stream-data input controller contains logic that controls the stream of input data and a register that is used to change the control mode of the CD-ROM decoder.
