Surface Mount Zero Bias Schottky Detector Diodes

Technical Data

Features
- Surface Mount SOT-23/SOT-143 Packages
- Miniature SOT-323 and SOT-363 Packages
- High Detection Sensitivity: up to 50 mV/µW at 915 MHz
- Low Flicker Noise: -162 dBV/Hz at 100 Hz
- Low FIT (Failure in Time) Rate*
- Tape and Reel Options Available
- Matched Diodes for Consistent Performance
- Better Thermal Conductivity for Higher Power Dissipation

* For more information see the Surface Mount Schottky Reliability Data Sheet.

Pin Connections and Package Marking

Notes:
1. Package marking provides orientation and identification.
2. See “Electrical Specifications” for appropriate package marking.

Description
Agilent’s HSMS-285x family of zero bias Schottky detector diodes has been designed and optimized for use in small signal (P_{in} < -20 dBm) applications at frequencies below 1.5 GHz. They are ideal for RF/ID and RF Tag applications where primary (DC bias) power is not available.

Important Note: For detector applications with input power levels greater than –20 dBm, use the HSMS-282x series at frequencies below 4.0 GHz, and the HSMS-286x series at frequencies above 4.0 GHz. The HSMS-285x series IS NOT RECOMMENDED for these higher power level applications.

Available in various package configurations, these detector diodes provide low cost solutions to a wide variety of design problems. Agilent’s manufacturing techniques assure that when two diodes are mounted into a single package, they are taken from adjacent sites on the wafer, assuring the highest possible degree of match.

Applications Information

Introduction

Agilent's HSMS-285x family of Schottky detector diodes has been developed specifically for low cost, high volume designs in small signal (Pin < -20 dBm) applications at frequencies below 1.5 GHz. At higher frequencies, the DC biased HSMS-286x family should be considered.

In large signal power or gain control applications (Pin > -20 dBm), the HSMS-282x and HSMS-286x products should be used. The HSMS-285x zero bias diode is not designed for large signal designs.

Schottky Barrier Diode Characteristics

Stripped of its package, a Schottky barrier diode chip consists of a metal-semiconductor barrier formed by deposition of a metal layer on a semiconductor. The most common of several different types, the passivated diode, is shown in Figure 5, along with its equivalent circuit.

Figure 5. Schottky Diode Chip.

$R_S$ is the parasitic series resistance of the diode, the sum of the bondwire and leadframe resistance, the resistance of the bulk layer of silicon, etc. RF energy coupled into $R_S$ is lost as heat — it does not contribute to the rectified output of the diode. $C_J$ is parasitic junction capacitance of the diode, controlled by the thickness of the epitaxial layer and the diameter of the Schottky contact. $R_J$ is the junction resistance of the diode, a function of the total current flowing through it.

\[
R_J = \frac{8.33 \times 10^5 \, nT}{I_S + I_b} = \frac{0.026}{I_S + I_b} \text{ at } 25^\circ C
\]

where

$n =$ ideality factor (see table of SPICE parameters)

$T =$ temperature in °K

$I_S =$ saturation current (see table of SPICE parameters)

$I_b =$ externally applied bias current in amps

$I_S$ is a function of diode barrier height, and can range from picoamps for high barrier diodes to as much as 5 µA for very low barrier diodes.

The Height of the Schottky Barrier

The current-voltage characteristic of a Schottky barrier diode at room temperature is described by the following equation:

\[
I = I_S \left( \exp \left( \frac{V - IR_S}{0.026} \right) - 1 \right)
\]

On a semi-log plot (as shown in the Agilent catalog) the current graph will be a straight line with inverse slope $2.3 \times 0.026 = 0.060$ volts per cycle (until the effect of $R_S$ is seen in a curve that droops at high current). All Schottky diode curves have the same slope, but not necessarily the same value of current for a given voltage. This is determined by the saturation current, $I_S$, and is related to the barrier height of the diode.

Through the choice of p-type or n-type silicon, and the selection of metal, one can tailor the characteristics of a Schottky diode. Barrier height will be altered, and at the same time $C_J$ and $R_S$ will be changed. In general, very low barrier height diodes (with high values of $I_S$, suitable for zero bias applications) are realized on p-type silicon. Such diodes suffer from higher values of $R_V$ than do the n-type. Thus, p-type diodes are generally reserved for small signal detector applications (where very high values of $R_V$ swamp out high $R_S$) and n-type diodes are used for mixer applications (where high L.O. drive levels keep $R_V$ low).

Measuring Diode Parameters

The measurement of the five elements which make up the low frequency equivalent circuit for a packaged Schottky diode (see Figure 6) is a complex task. Various techniques are used for each element. The task begins with the elements of the diode chip itself.

Figure 6. Equivalent Circuit of a Schottky Diode.
RS is perhaps the easiest to measure accurately. The V-I curve is measured for the diode under forward bias, and the slope of the curve is taken at some relatively high value of current (such as 5 mA). This slope is converted into a resistance Rd.

\[ R_S = R_d - \frac{0.026}{I_f} \]

RV and CJ are very difficult to measure. Consider the impedance of CJ = 0.16 pF when measured at 1 MHz — it is approximately 1 MΩ. For a well designed zero bias Schottky, RV is in the range of 5 to 25 KΩ, and it shorts out the junction capacitance. Moving up to a higher frequency enables the measurement of the capacitance, but it then shorts out the video resistance. The best measurement technique is to mount the diode in series in a 50 Ω microstrip test circuit and measure its insertion loss at low power levels (around -20 dBm) using an HP8753C network analyzer. The resulting display will appear as shown in Figure 7.

\[ \text{Figure 7. Measuring } C_J \text{ and } R_V. \]

At frequencies below 10 MHz, the video resistance dominates the loss and can easily be calculated from it. At frequencies above 300 MHz, the junction capacitance sets the loss, which plots out as a straight line when frequency is plotted on a log scale. Again, calculation is straightforward.

LP and CP are best measured on the HP8753C, with the diode terminating a 50 Ω line on the input port. The resulting tabulation of S11 can be put into a microwave linear analysis program having the five element equivalent circuit with RV, CJ and RS fixed. The optimizer can then adjust the values of LP and CP until the calculated S11 matches the measured values. Note that extreme care must be taken to de-embed the parasitics of the 50 Ω test fixture.

Detector Circuits

When DC bias is available, Schottky diode detector circuits can be used to create low cost RF and microwave receivers with a sensitivity of -55 dBm to -57 dBm.[1] These circuits can take a variety of forms, but in the most simple case they appear as shown in Figure 8. This is the basic detector circuit used with the HSMS-285x family of diodes.

In the design of such detector circuits, the starting point is the equivalent circuit of the diode, as shown in Figure 6.

Of interest in the design of the video portion of the circuit is the diode's video impedance — the other four elements of the equivalent circuit disappear at all reasonable video frequencies. In general, the lower the diode's video impedance, the better the design.

\[ RV = \frac{26,000}{I_S + I_b} \]

where

- \( I_S = \text{diode saturation current in } \mu\text{A} \)
- \( I_b = \text{bias current in } \mu\text{A} \)

Saturation current is a function of the diode's design,[2] and it is a constant at a given temperature. For the HSMS-285x series, it is typically 3 to 5 µA at 25°C.

Saturation current sets the detection sensitivity, video resistance and input RF impedance of the zero bias Schottky detector diode.

---

Since no external bias is used with the HSMS-285x series, a single transfer curve at any given frequency is obtained, as shown in Figure 2.

The most difficult part of the design of a detector circuit is the input impedance matching network. For very broadband detectors, a shunt 60 Ω resistor will give good input match, but at the expense of detection sensitivity.

When maximum sensitivity is required over a narrow band of frequencies, a reactive matching network is optimum. Such networks can be realized in either lumped or distributed elements, depending upon frequency, size constraints and cost limitations, but certain general design principals exist for all types. Design work begins with the RF impedance of the HSMS-285x series, which is given in Figure 9.

![Smith Chart](image)

**Figure 9. RF Impedance of the HSMS-285x Series at -40 dBm.**

**915 MHz Detector Circuit**

Figure 10 illustrates a simple impedance matching network for a 915 MHz detector.

![Impedance Matching Network](image)

**Figure 10. 915 MHz Matching Network for the HSMS-285x Series at Zero Bias.**

A 65 nH inductor rotates the impedance of the diode to a point on the Smith Chart where a shunt inductor can pull it up to the center. The short length of 0.065" wide microstrip line is used to mount the lead of the diode’s SOT-323 package. A shorted shunt stub of length <λ/4 provides the necessary shunt inductance and simultaneously provides the return circuit for the current generated in the diode. The impedance of this circuit is given in Figure 11.

![Impedance Chart](image)

**Figure 11. Input Impedance.**

The input match, expressed in terms of return loss, is given in Figure 12.

![Return Loss Chart](image)

**Figure 12. Input Return Loss.**

As can be seen, the band over which a good match is achieved is more than adequate for 915 MHz RFID applications.

**Voltage Doublers**

To this point, we have restricted our discussion to single diode detectors. A glance at Figure 8, however, will lead to the suggestion that the two types of single diode detectors be combined into a two diode voltage doubler (known also as a full wave rectifier). Such a detector is shown in Figure 13.

![Voltage Doubler Circuit](image)

**Figure 13. Voltage Doubler Circuit.**

Such a circuit offers several advantages. First the voltage outputs of two diodes are added in series, increasing the overall value of voltage sensitivity for the network (compared to a single diode detector). Second, the RF impedances of the two diodes are added in parallel, making the job of reactive matching a bit easier.

---

Such a circuit can easily be realized using the two series diodes in the HSMS-285C.

**Flicker Noise**
Reference to Figure 5 will show that there is a junction of metal, silicon, and passivation around the rim of the Schottky contact. It is in this three-way junction that flicker noise\(^\text{[5]}\) is generated. This noise can severely reduce the sensitivity of a crystal video receiver utilizing a Schottky detector circuit if the video frequency is below the noise corner. Flicker noise can be substantially reduced by the elimination of passivation, but such diodes cannot be mounted in non-hermetic packages. \(p\)-type silicon Schottky diodes have the least flicker noise at a given value of external bias (compared to \(n\)-type silicon or GaAs). At zero bias, such diodes can have extremely low values of flicker noise. For the HSMS-285x series, the noise temperature ratio is given in Figure 14.

For an ideal resistor \(R\), at 300\(^\circ\)K, the noise voltage can be computed from

\[ v = 1.287 \times 10^{-10} \sqrt{\vphantom{R}R} \text{ volts/Hz} \]

which can be expressed as

\[ 20 \log_{10} v \text{ dBV/Hz} \]

Thus, for a diode with \(R_V = 9 \text{ K}\)\(\Omega\), the noise voltage is 12.2 nV/Hz or -158 dBV/Hz. On the graph of Figure 14, -158 dBV/Hz would replace the zero on the vertical scale to convert the chart to one of absolute noise voltage vs. frequency.

**Diode Burnout**
Any Schottky junction, be it an RF diode or the gate of a MESFET, is relatively delicate and can be burned out with excessive RF power. Many crystal video receivers used in RFID (tag) applications find themselves in poorly controlled environments where high power sources may be present. Examples are the areas around airport and FAA radars, nearby ham radio operators, the vicinity of a broadcast band transmitter, etc. In such environments, the Schottky diodes of the receiver can be protected by a device known as a limiter diode.\(^\text{[6]}\)

Formerly available only in radar warning receivers and other high cost electronic warfare applications, these diodes have been adapted to commercial and consumer circuits.

Agilent offers a complete line of surface mountable PIN limiter diodes. Most notably, our HSMP-4820 (SOT-23) can act as a very fast (nanosecond) power-sensitive switch when placed between the antenna and the Schottky diode, shorting out the RF circuit temporarily and reflecting the excessive RF energy back out the antenna.

**Assembly Instructions**

**SOT-323 PCB Footprint**
A recommended PCB pad layout for the miniature SOT-323 (SC-70) package is shown in Figure 15 (dimensions are in inches). This layout provides ample allowance for package placement by automated assembly equipment without adding parasitics that could impair the performance. Figure 16 shows the pad layout for the six-lead SOT-363.

---

\[^{[6]}\text{Agilent Application Note 1050, Low Cost, Surface Mount Power Limiters.}\]
SMT Assembly
Reliable assembly of surface mount components is a complex process that involves many material, process, and equipment factors, including: method of heating (e.g., IR or vapor phase reflow, wave soldering, etc.) circuit board material, conductor thickness and pattern, type of solder alloy, and the thermal conductivity and thermal mass of components. Components with a low mass, such as the SOT packages, will reach solder reflow temperatures faster than those with a greater mass.

Agilent’s diodes have been qualified to the time-temperature profile shown in Figure 17. This profile is representative of an IR reflow type of surface mount assembly process. After ramping up from room temperature, the circuit board with components attached to it (held in place with solder paste) passes through one or more preheat zones. The preheat zones increase the temperature of the board and components to prevent thermal shock and begin evaporating solvents from the solder paste. The reflow zone briefly elevates the temperature sufficiently to produce a reflow of the solder.

The rates of change of temperature for the ramp-up and cool-down zones are chosen to be low enough to not cause deformation of the board or damage to components due to thermal shock. The maximum temperature in the reflow zone ($T_{MAX}$) should not exceed 235°C.

These parameters are typical for a surface mount assembly process for Agilent diodes. As a general guideline, the circuit board and components should be exposed only to the minimum temperatures and times necessary to achieve a uniform reflow of solder.
