

Integrated Device Technology, Inc.

16-BIT CMOS CASCADABLE ALU

IDT7381
IDT7383

FEATURES:

- High-performance 16-bit Arithmetic Logic Unit (ALU)
- 16ns to 55ns clocked ALU operations
- Ideal for radar, sonar or image processing applications
- IDT7381:
 - 54/74S381 instruction set (8 functions)
 - Replaces Gould S614381 or Logic Devices L4C381
 - Cascadable with or without carry look-ahead
- IDT7383:
 - 32 advanced ALU functions
 - Cascadable without carry look-ahead
- Pipeline or flow-through modes
- Internal feedback path for accumulation
- Three-state outputs
- TTL-compatible
- Produced with advanced submicron CMOS technology
- Available in 68-lead PGA, 68-pin surface mount PLCC and 68-pin fine-pitch Flatpack (7383 only)
- Military product compliant to MIL-STD-883, Class B
- Speeds available:
 - Commercial: L/16/20/25/30/40/55
 - Military: L/20/25/30/35/45/65

DESCRIPTION:

The IDT7381 and IDT7383 are high-speed cascadable Arithmetic Logic Unit (ALUs). Both three-bus devices have two input registers, ultra-fast 16-bit ALUs and 16-bit output registers. With IDT's high-performance CMOS technology, the IDT7381/7383 can do arithmetic or logic operations in 20ns. The IDT7381 functionally replaces four 54/74S381 four-bit ALUs in a 68-pin package.

The two input operands, A and B, can be clocked or fed through for flexible pipelining. The F output can also be set into clocked or flow-through mode. An output enable is provided for three-state control of the output port on a bus.

The IDT7381 has three function pins to select 1 of 8 arithmetic or logic operations. The two R and S selection pins determine whether A, B, F or 0 are fed into the ALU. This ALU has carry-out, propagate and generate outputs for cascading using carry look-ahead.

The IDT7383 has five function pins to select 1 of 32 arithmetic or logic operations. This ALU has a carry-out pin for cascading.

The IDT7381 and IDT7383 are available in 68-pin PLCC or PGA packages. Military grade product is manufactured in compliant with the latest revision of MIL-STD-883, Class B, for high reliability systems.

PIN DESCRIPTIONS

IDT7381 AND IDT7383 PIN DESCRIPTION

Pin Name	I/O	Description
A0 - A15	I	Sixteen-bit data input port.
B0 - B15	I	Sixteen-bit data input port.
ENA	I	Register enable for the A input port; active low pin.
$\overline{\text{ENB}}$	I	Register enable for the B input port; active low pin.
FTAB	I	Flow-through control pin. When this pin is high, both register A and B are transparent.
F0 - F15	O	Sixteen-bit data output port.
$\overline{\text{ENF}}$	I	Register enable for the F output port; active low pin.
FTF	I	Flow-through control pin. When this pin is high, the F register is transparent.
CLK	I	Clock input.
OE	I	Output enable control pin. When this pin is high, the output port F is in a high impedance state. When low, the output port F is active.
C0	I	Carry input. This pin receives arithmetic carries from less significant ALU components in a cascade configuration.
C16	O	Carry output. This pin produces arithmetic carries to more significant ALU components in a cascaded configuration.
OVF	O	This pin indicates a two's complement arithmetic overflow, when high.
Z	O	This pin indicates a zero output result, when high.
Vcc		Power supply pin, 5V.
GND		Ground pin, 0V. There are two ground pins on the IDT7383.

2525 tbl 01

IDT7381 PINS

Pin Name	I/O	Description
RS0 - RS1	I	Two control pins used to select input operands for the R and S multiplexers.
I0 - I2	I	Three control pins to select the ALU function performed.
P	O	Indicates the carry propagate output state to the ALU.
$\overline{\text{G}}$	O	Indicates the carry generate output state to the ALU.

2525 tbl 02

IDT7383 PINS

Pin Name	I/O	Description
I0 - I4	I	Five control pins to select the ALU function performed.
N	O	The sign bit of an ALU operation.

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Symbol	Rating	Com'l.	Mil.	Unit
V _{TERM}	Terminal Voltage with Respect to Ground	−0.5 to V _{CC} + 0.5	−0.5 to V _{CC} + 0.5	V
V _{CC}	Power Supply Voltage	−0.5 to +7.0	−0.5 to +7.0	V
T _A	Operating Temperature	0 to +70	−55 to +125	°C
T _{BIAS}	Temperature Under Bias	−55 to +125	−65 to +135	°C
T _{STG}	Storage Temperature	−55 to +125	−65 to +150	°C
P _T	Power Dissipation	1.0	1.0	W
I _{OUT}	DC Output Current	50	50	mA

NOTE:

2525 tbl 07

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Under no circumstances should an input of an I/O Pin be greater than V_{CC} + 0.5V.

CAPACITANCE (T_A = +25°C, f = 1.0MHz)

V_{OL}	Output LOW Voltage	$V_{CC} = \text{Min.}$ $V_{IN} = V_{IH}$ or V_{IL}	$I_{OL} = 4\text{mA MIL.}$	—	—	0.5	V
			$I_{OL} = 8\text{mA COM'L.}$				

NOTES:

2525 tbl 08

1. For conditions shown as Max. or Min., use appropriate value specified under Electrical Characteristics for the applicable device type.
2. Typical values are at $V_{CC} = 5.0\text{V}$, $+25^{\circ}\text{C}$ ambient and maximum loading.
3. Not more than one output should be shorted at one time. Duration of the short circuit test should not exceed one second.

POWER SUPPLY CHARACTERISTICS

Commercial: TA = 0°C to +70°C, VCC = 5.0V ± 5%; Military: TA = -55°C to +125°C, VCC = 5.0V ± 10%

NOTES:

2525 tbl 10

- For conditions shown as Max. or Min., use appropriate value specified under Electrical Characteristics for the applicable device type.
- Typical values are at V_{CC} = 5.0V, +25°C ambient.
- Per TTL driven input (V_{IN} = 3.4V); all other inputs at V_{CC} or GND.
- This parameter is not directly testable, but is derived from I_{CCD1} for use in Total Power Supply calculations.
- Total power supply current is calculated as follows:

$$I_C = I_{QUIESCENT} + I_{INPUTS} + I_{DYNAMIC}$$

$$I_C = I_{CC} + \Delta I_{CC} D_{HNT} + I_{CCD} (f_{CP} + f_i N_i)$$

$$I_{CC} = \text{Quiescent Current}$$

$$\Delta I_{CC} = \text{Power Supply Current for a TTL High Input (V}_{IN} = 3.4V)$$

$$D_{HNT} = \text{Duty Cycle for TTL Inputs High}$$

$$N_T = \text{Number of TTL Inputs at } D_H$$

$$I_{CCD} = \text{Dynamic Current Caused by an Output Transition Pair (HLH or LHL)}$$

$$f_{CP} = \text{Clock Frequency for Register Devices (Zero for Non-Register Devices)}$$

$$f_i = \text{Input Frequency}$$

$$N_i = \text{Number of Inputs at } f_i$$
All currents are in milliamperes and all frequencies are in megahertz.
- This parameter is not production tested but is an indicator of the power dissipated with outputs loaded.
- Values for these conditions are examples of the I_C formula in note 5 above. These are guaranteed but not tested.

CASCADING THE IDT7381/3

Some applications require 32-bit or wider input operands. Cascading is the hardware solution. It provides a high speed alternative in handling more than 16-bit wide operands.

This section is divided in three parts:

1. Cascading the IDT7381
2. Cascading the IDT7383
3. Time delay considerations

1. Cascading the IDT7381

Cascading to 32-bit wide operands takes only two IDT7381s and no external hardware. However, cascading to data widths greater than 32-bit can be done in two ways: without external hardware (slow method) or by using a carry look ahead generator like FCT182 (fast method).

a) Cascading the IDT7381 without a carry-look-ahead generator: (Figures 1 and 2)

1. Connect the C16 output of the least significant device into the Co input of the next most significant device.
2. Common lines to all devices are: RS0–1, I0–2, Clk, FTF, FTAB, $\overline{\text{ENA}}$, $\overline{\text{ENB}}$, $\overline{\text{ENF}}$.
3. Take OVF, C16, $\overline{\text{P}}$, $\overline{\text{G}}$ of the most significant device as valid.
4. The system's zero flag (Z) is obtained by ANDing all zero flag results.

b) Cascading three or more IDT7381s with carry-look-ahead (CLA) generator: (Figure 3)

1. Connect the $\overline{\text{P}}$ and $\overline{\text{G}}$ outputs of each device to the CLA generator's corresponding inputs.
2. Take the CLA generator outputs into the Co inputs of each device (except for the least significant one).
3. Common lines to all devices are: RS0–1, I0–2, Clk, FTF, FTAB, $\overline{\text{ENA}}$, $\overline{\text{ENB}}$, $\overline{\text{ENF}}$.
4. Take OVF, C16, $\overline{\text{P}}$, $\overline{\text{G}}$ of the most significant device as valid.
5. Carry-in to the system should be connected to the Co input of the least significant device and also to the CLA generator.

2. Cascading the IDT7383

(Figures 4 and 5)

1. Connect the C16 output of the least significant device into the Co input of the next most significant device.
2. Common lines to all devices are: I0–4, Clk, FTF, FTAB, $\overline{\text{ENA}}$, $\overline{\text{ENB}}$, $\overline{\text{ENF}}$.
3. Take OVF, C16, N of the most significant device as valid.
4. The system's zero flag (Z) is obtained by ANDing all zero flag results.

3. Time Delay Considerations

Once cascading has taken place, time delays may become critical in high performance systems. Our main interest here is focused on "propagation delays", i.e. calculating the time required for an input signal to propagate through several cascaded devices up to a specific output in another device within the cascaded system.

Propagation Delay

The propagation delay *for two devices* between the input and output of interest (input to output delay) is done as follows:

1. Calculate delay between the input and C16 in the first device.
2. Calculate delay between Co and the output in the second device.
3. Add both results.

The following table is an example on how to build a propagation delay table for all inputs in a 32-bit IDT7381/3 cascaded system.

Propagation delay calculations can be extended to *n-cascaded* devices as the sum of the delays in all devices between the input and output of interest. That is:

$$(\text{Input})_1 \rightarrow (\text{C16})_1 = t_1$$

...

$$(\text{Co})_i \rightarrow (\text{C16})_i = t_i$$

$$(\text{Co})_{i+1} \rightarrow (\text{C16})_{i+1} = t_{i+1}$$

...

$$(\text{Co})_n \rightarrow (\text{Output})_n = t_n$$

Where the subscript *i* denotes the device number and the arrow ($\rightarrow$) represents the delay in between. Notice that *i + 1* is the immediate upper device from device *i*. Adding the delays *t_i* we get:

$$\text{Propagation delay} = t_1 + t_2 + \dots + t_i + t_{i+1} + \dots + t_n$$

Total Delay

As seen from Figure 10, the propagation delay is within the IDT7381/3 devices only. A complete analysis should also include the delay associated with the transmission line *L_i* (which depends on the line length and its impedance). This line delay should then be added to the propagation delay to obtain the total delay for the cascaded system:

$$\text{Total delay} = \text{Propagation delay} + \text{Transmission line delay}$$
