

RC190xx

PCIe Gen5/6 Fanout Buffer Family with LOS

The RC190xx (RC19024, RC19020, RC19020A072, RC19016, RC19013, RC19008, RC19004, and RC19002) ultra-high performance fanout buffers support PCIe Gen5 and Gen6. They provide a Loss-Of-Signal (LOS) output for system monitoring and redundancy. The devices also incorporate Power Down Tolerant (PDT) and Flexible Startup Sequencing (FSS) features, easing system design. They can drive both source-terminated and double-terminated loads, operating up to 400MHz.

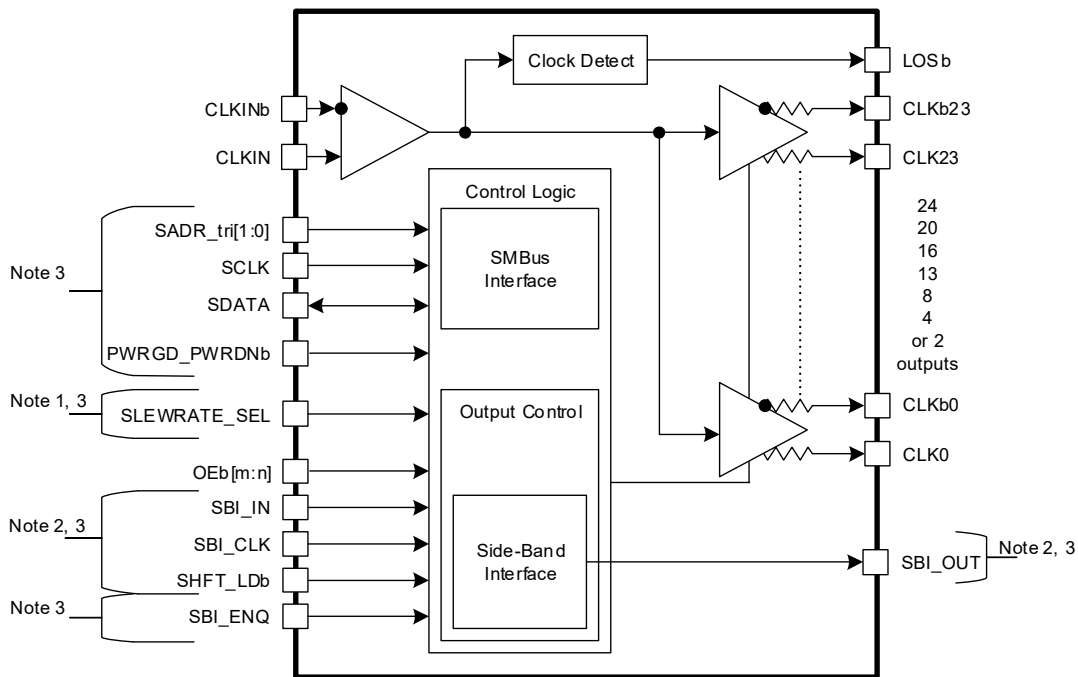

The family offers 2, 4, 8, 13, 16, 20, and 24 Low-Power (LP) HCSL output pairs in 3 × 3 mm to 10 × 10 mm packages. The RC190xx devices offer higher output counts in smaller packages compared to earlier buffer families. The buffers support both Common Clock (CC) and Independent Reference (IR) PCIe clock architectures.

Applications

- Cloud/High-performance computing
- nVME storage
- Networking
- Accelerators

Features

- PCIe Gen5 additive phase jitter: 6fs RMS
- PCIe Gen6 additive phase jitter: 4fs RMS
- DB2000Q additive phase jitter: 10fs RMS
- 12kHz to 20MHz additive phase jitter: 30fs RMS at 156.25MHz
- Power Down Tolerant (PDT) inputs
- Flexible Startup Sequencing (FSS)
- Automatic Clock Parking (ACP) upon loss of CLKIN
- Spread-spectrum tolerant
- CLKIN accepts HCSL or LVDS signal levels
- -40 to +105°C, 3.3V ±10% operation
- All devices except RC19002:
 - Selectable output slew rate via pin/SMBus
 - 4-wire Side-Band Interface supports high-speed serial output enable and device daisy-chaining
 - 9 SMBus addresses plus write protection
 - 85Ω or 100Ω (A100 suffix) output impedance
 - Pin-selectable slew rate
- RC19002: Pin-selectable output impedance

1. RC19016/13/08/04 only. Other devices use SMBus.
 2. Some devices mux SBI with OEb pins. See specific pinouts. Devices with SBI have dedicated SBI_ENQ pin.
 3. Does not apply to the RC19002. On RC19002, the SLEWRATE_SEL pin is ZOUT_SEL.

1. Pin Information

1.1 Signal Types

Term	Description
I	Input
O	Input
OD	Open Drain Output
I/O	Bi-Directional
PD	Pull-down
PU	Pull-up
Z	Tristate
D	Driven
X	Don't care
SE	Single ended
DIF	Differential
PWR	3.3 V power
GND	Ground
PDT	Power Down Tolerant: These signals must tolerate being driven when the device is powered down.

Note that some pins have both internal pull-up and pull-down resistors which bias the pins to VDD/2. Other pins are multi-mode and have an internal pull-up or internal pull-down depending on the mode.

1.2.2 RC19024 Pin Descriptions

Table 1. RC19024 Pin Descriptions

Pin Number	Pin Name	Pin Type	Description
A1	OEb23_SBI_CLK	I, SE, PD, PDT	Active low input for enabling output 23 or the clock pin for the SBI shift register. The function of this pin is controlled by the SBEN or SBI_ENQ pin. For more information, see Side-Band Interface (SBI) . OE mode: 0 = enable output, 1 = disable output. Side-Band mode: Clocks data into the SBI on the rising edge.
A2	CLK23B	O, DIF	Complementary clock output.
A3	CLK23	O, DIF	True clock output.
A4	CLKINb	I, DIF, PDT	Complementary clock input.
A5	CLKIN	I, DIF, PDT	True clock input.
A6	SBI_ENQ	I, SE, PD, PDT	Input that selects function of pins that are multiplexed between OE and SBI functionality. SMBus output enable bits and non-multiplexed OE pins remain functional when SBI is enabled. This pin must be strapped to its desired state. It cannot dynamically change. 0 = SBI is disabled. Multiplexed pins function as output enables. 1 = SBI is enabled. Multiplexed pins function as SBI control pins.
A7	PWRGD_PWRDNb	I, SE, PU, PDT	Input notifies device to sample Latched inputs and start up on first high assertion. Low enters Power Down Mode, subsequent high assertions exit Power Down Mode.
A8	SADR_tri0	I, SE, PD, PU	SMBus address bit. This is a tri-level input that works in conjunction with other SADR pins, if present, to decode SMBus Addresses. See the SMBus Address Decode table and the tri-level input thresholds in the electrical tables.
A9	SCLK	I, SE, PDT	Clock pin of SMBus interface.
A10	SDAT	I/O, OD, PDT	Data pin for SMBus interface.
A11	CLK0b	O, DIF	Complementary clock output.
A12	CLK0	O, DIF	True clock output.

1. The Refclk jitter is measured after applying the filter functions found in the *PCI Express Base Specification 6.0, Revision 1.0*. For the exact measurement setup, see [Test Loads](#). The worst case results for each data rate are summarized in this table. Equipment noise is removed from all measurements.
2. Jitter measurements should be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately, jitter measurements can be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200MHz (at 300MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5GT/s data rate, the RMS jitter is converted to peak-to-peak jitter using a multiplication factor of 8.83.
3. SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2MHz taking care to minimize removal of any non-SSC content.
4. Note that 0.7ps RMS is to be used in channel simulations to account for additional noise in a real system.
5. Note that 0.25ps RMS is to be used in channel simulations to account for additional noise in a real system.
6. The rms sum of the source jitter and the additive jitter (arithmetic sum for PCIe Gen1) must be less than the jitter specification listed.
7. The *PCI Express Base Specification 6.0, Revision 1.0* provides the filters necessary to calculate SRIS jitter values; it does not provide specification limits, therefore, the reference to this footnote in the Limit column. SRIS values are informative only. A common practice is to split the common clock budget in half. For 16GT/s data rates and above, the user must choose whether to use the output jitter specification, or the input jitter specification, which includes an allocation for the jitter added by the channel. Using 32GT/s, the Refclk jitter budget is 150fs RMS. One half of the Refclk jitter budget is 106fs RMS. At the clock input, the system must deliver 250fs RMS. One half of this value is 177fs RMS. If the clock is placed next to the PCIe device in an SRIS system, the channel is very short and the user can choose to use this more relaxed value as the jitter limit.
8. Differential input swing $\geq 1600mV$ and input slew rate $\geq 3.5V/ns$

$t_{LOSDeassert}$	LOS De-assert Time	Time from appearance of input clock to LOS de-assert. ^{[3][5]}	-	6	9	clks

1. Measured from when all power supplies have reached > 90% of nominal voltage to the first stable clock edge on the output. PWRGD_PWRDNb tied to VDD in this case.
2. VDD stable, measured from de-assertion of PWRGD_PWRDNb.
3. The clock detect circuit does not qualify the accuracy of the input clock. The first input clock must appear to release the power on reset and enable the LOS circuit at power up.
4. PWRGD_PWRDNb high. The Automatic Clock Parking (ACP) circuit - if enabled - will park the outputs in a low/low state within this time. See Byte4, bit 4 LOSb_ACP_ENABLE.
5. PWRGD_PWRDNb high. The device will drive the outputs to a high/low state within this time and then begin clocking the outputs.

1. Standard high impedance load with $C_L = 2pF$. See [Test Loads](#).
2. The specification limits are taken from either the *PCIe Base Specification Revision 6.0* or from relevant x86 processor specifications, whichever is more stringent.
3. Measured from single-ended waveform.
4. Defined as the maximum instantaneous voltage including overshoot.
5. Defined as the minimum instantaneous voltage including undershoot.

6. Measured at crossing point where the instantaneous voltage value of the rising edge of REFCLK+ equals the falling edge of REFCLK-.
7. Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement.
8. Defined as the total variation of all crossing voltages of Rising REFCLK+ and Falling REFCLK-. This is the maximum allowed variance in VCROSS for any particular system.
9. Measured from differential waveform.
10. Measured from -150 mV to +150 mV on the differential waveform (derived from REFCLK+ minus REFCLK-). The signal must be monotonic through the measurement region for rise and fall time. The 300 mV measurement window is centered on the differential zero crossing.
11. Matching applies to rising edge rate for REFCLK+ and falling edge rate for REFCLK-. It is measured using a ±75 mV window centered on the median cross point where REFCLK+ rising meets REFCLK- falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations. The Rise Edge Rate of REFCLK+ should be compared to the Fall Edge Rate of REFCLK-; the maximum allowed difference should not exceed 20% of the slowest edge rate.

1. Standard high impedance load with $C_L = 2pF$. For more information, see [Test Loads](#).
2. The specification limits are taken from either the *PCIe Base Specification Revision 6.0* or from relevant x86 processor specifications, whichever is more stringent.
3. Measured from single-ended waveform.
4. Defined as the maximum instantaneous voltage including overshoot.

5. Defined as the minimum instantaneous voltage including undershoot.
6. Measured at crossing point where the instantaneous voltage value of the rising edge of REFCLK+ equals the falling edge of REFCLK-.
7. Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement.
8. Defined as the total variation of all crossing voltages of Rising REFCLK+ and Falling REFCLK-. This is the maximum allowed variance in VCROSS for any particular system.
9. Measured from differential waveform.
10. Measured from -150mV to +150mV on the differential waveform (derived from REFCLK+ minus REFCLK-). The signal must be monotonic through the measurement region for rise and fall time. The 300mV measurement window is centered on the differential zero crossing.
11. Matching applies to rising edge rate for REFCLK+ and falling edge rate for REFCLK-. It is measured using a ±75mV window centered on the median cross point where REFCLK+ rising meets REFCLK- falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations. The Rise Edge Rate of REFCLK+ should be compared to the Fall Edge Rate of REFCLK-; the maximum allowed difference should not exceed 20% of the slowest edge rate.

- For more information, see [Test Loads](#).
- Output voltage set to 800mV. Slew rate has negligible effect on current consumption, so only fast is listed.
- Total operating current is obtained by adding IDDCLK + IDDDIG, or IDDCLK + IDDR for a particular device and operating mode. Power down current is obtained by adding IDDCLK_PD + IDDDIG_PD, or IDDCLK_PD + IDDR_PD for a particular device.

2.4.8 CLKIN AC/DC Characteristics

Table 26. CLKIN AC/DC Characteristic

Symbol	Parameter	Condition	Minimum [1]	Typical	Maximum	Unit
V _{CROSS}	Input Crossover Voltage	-	100	-	1400	mV
V _{SWING}	Input Swing	Differential value.	200	-	-	mV
dv/dt	Input Slew Rate	Measured differentially. [2]	0.6	-	-	V/ns

- For values required for performance, see the [Phase Jitter](#) tables.
- Measured from -150mV to +150mV on the differential waveform (derived from REFCLK+ minus REFCLK-). The signal must be monotonic through the measurement region for rise and fall time. The 300mV measurement window is centered on the differential zero-crossing.

t _R	Clock/Data Rise Time	[9]	-	1000	-	300	ns
t _{SPIKE}	Noise Spike Suppression Time	[10]	-	-	0	50	ns

- Power must be applied and PWRGD_PWRDNb must be a 1 for the SMBus to be active.

2. A master should not drive the clock at a frequency below the minimum f_{SMB} . Further, the operating clock frequency should not be reduced below the minimum value of f_{SMB} due to periodic clock extending by slave devices as defined in Section 5.3.3 of System Management Bus (SMBus) Specification, Version 3.1, dated 19 Mar 2018. This limit does not apply to the bus idle condition, and this limit is independent from the $t_{LOW:SEXT}$ and $t_{LOW:MEXT}$ limits. For example, if the SMBCLK is high for $t_{HIGH,MAX}$, the clock must not be periodically stretched longer than $1/f_{SMB,MIN} - t_{HIGH,MAX}$. This requirement does not pertain to a device that extends the SMBCLK low for data processing of a received byte, data buffering and so forth for longer than 100 μs in a non-periodic way.
3. A device must internally provide sufficient hold time for the SMBDAT signal (with respect to the $V_{IH,MIN}$ of the SMBCLK signal) to bridge the undefined region of the falling edge of SMBCLK.
4. Slave devices may have caused other slave devices to hold SDA low. This is the maximum time that a device can hold SMBDAT low after the master raises SMBCLK after the last bit of a transaction. A slave device may detect how long SDA is held low and release SDA after the time out period.
5. Devices participating in a transfer can abort the transfer in progress and release the bus when any single clock low interval exceeds the value of $t_{TIMEOUT,MIN}$. After the master in a transaction detects this condition, it must generate a stop condition within or after the current data byte in the transfer process. Devices that have detected this condition must reset their communication and be able to receive a new START condition no later than $t_{TIMEOUT,MAX}$. Typical device examples include the host controller, and embedded controller, and most devices that can master the SMBus. Some simple devices do not contain a clock low drive circuit; this simple kind of device typically may reset its communications port after a start or a stop condition. A timeout condition can only be ensured if the device that is forcing the timeout holds the SMBCLK low for $t_{TIMEOUT,MAX}$ or longer.
6. The device has the option of detecting a timeout if the SMBDATA pin is also low for this time.
7. $t_{HIGH,MAX}$ provides a simple guaranteed method for masters to detect bus idle conditions. A master can assume that the bus is free if it detects that the clock and data signals have been high for greater than $t_{HIGH,MAX}$.
8. $t_{LOW:MEXT}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master will also extend the clock causing the combined clock low time to be greater than $t_{LOW:MEXT}$ on a given byte. This parameter is measured with a full speed slave device as the sole target of the master.
9. The rise and fall time measurement limits are defined as follows:
 - Rise Time Limits: ($V_{IL,MAX} - 0.15 V$) to ($V_{IH,MIN} + 0.15 V$)
 - Fall Time Limits: ($V_{IH,MIN} + 0.15 V$) to ($V_{IL,MAX} - 0.15 V$)
10. Devices must provide a means to reject noise spikes of a duration up to the maximum specified value.

2.4.10 Side-Band Interface

This section applies to all device except the RC19002 because the RC19002 does not have a Side Band Interface.

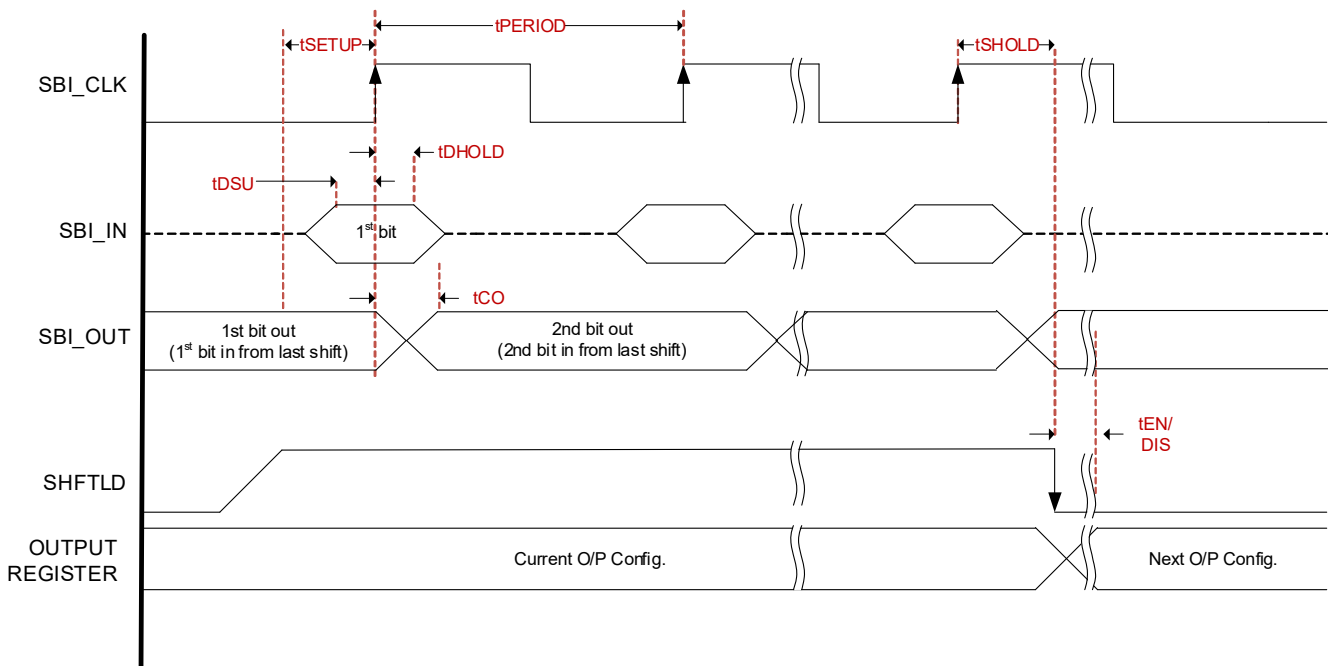

Figure 12. Side-Band Interface Timing

Figure 12 is the timing diagram and Table 29 provides the electrical characteristics for the Side-Band Interface. The SBI supports clock rates up to 25MHz.

Table 29. Electrical Characteristics – Side-Band Interface

Symbol	Parameter	Condition	Minimum	Typical	Maximum	Unit
t_{PERIOD}	Clock Period	Clock period.	40	-	-	ns
t_{SETUP}	SHFT Setup Time to Clock	SHFT_LDB high to SBI_CLK rising edge.	10	-	-	ns
t_{DSU}	SBI_IN Setup Time	SBI_IN setup to SBI_CLK rising edge.	5	-	-	ns
t_{DHOLD}	SBI_IN Hold Time	SBI_IN hold after SBI_CLK rising edge.	2	-	-	ns
t_{CO}	SBI_CLK to SBI_OUT	SBI_CLK rising edge to SBI_OUT valid.	2	-	-	ns
t_{SHOLD}	SHFT Hold Time	SHFT_LDB hold (high) after SBI_CLK rising edge (SBI_CLK to SHFT_LDB falling edge).	10	-	-	ns
$t_{EN/DIS}$	Enable/Disable Time	Delay from SHFT_LDB falling edge to next output configuration taking effect. ^[1]	4	-	12	clocks
t_{SLEW}	Slew Rate	SBI_CLK (between 20% and 80%). ^[2]	0.7	-	6	V/ns

1. Refers to the output clock.
2. Control input must be monotonic from 20% to 80% of input swing.

5. Applications Information

5.1 Inputs, Outputs, and Output Enable Control

5.1.1 Recommendations for Unused Inputs and Outputs

5.1.1.1 Unused Differential CLKIN Inputs

The CLKIN/CLKINb inputs of the RC19xxx devices have internal bias networks that protect the devices from a floating input clock condition.

5.1.1.2 Unused Single-ended Control Inputs

The single-ended control pins have internal pull-up and/or internal pull-down resistors and do not require external resistors. They can be left floating if the default pin state is the desired state. If external resistors are needed to change the pin state or are desired for design robustness, 10kohm is the recommended value.

5.1.1.3 Unused Differential CLK Outputs

All unused CLK outputs can be left floating. Renesas recommends that no trace be attached to unused CLK outputs. While not required (but is highly recommended), the best design practice is to disable unused CLK outputs.

5.1.1.4 Unused SMBus Clock and Data Pins

If the SMBus interface is not used, the clock and data pins must be pulled high with an external resistor. The two pins can share a resistor if there is no possibility of using the SMBus interface for debug purposes. If the interface may be used for debug, separate resistors should be used. 10kohm is the recommended value.

5.1.2 Differential CLKIN Configurations

The RC19xxx clock input buffer supports four configurations:

- Direct connection to HCSL-level inputs
- Direct connection to LVDS-level inputs with *external* termination resistor
- Internal self-bias circuit for applications that *externally* AC-couple the input clock
This feature is enabled by the **AC_IN** bit.
- Internal pull-down resistors (R_p) to terminate the clock input at the receiver.
This feature is enabled by the **Rx_TERM** bit.

Devices with multiple input clocks have individual AC_IN and Rx_TERM configuration bits for each input. The internal input clock terminations prevent reflections and are useful for non-PCIe applications, where the frequency and transmission line length vary from the 100MHz PCIe standard.

Figure 16 through Figure 19 illustrate the above items.

Figure 17. LVDS Input Levels

Figure 18. External AC-Coupling

Figure 19. Receiver Termination

5.1.3 Differential CLK Output Configurations

5.1.3.1 Direct-Coupled HCSL Loads

The RC190 LP-HCSL CLK outputs have internal source terminations and directly drive industry-standard HCSL-level inputs with no external components. They support both 85ohm and 100ohm differential impedances. The CLK outputs can also drive receiver-terminated HCSL loads. The combination of source termination and receiver termination results in a double-terminated load. When double-terminated, the CLK output swing will be half of the source-terminated values.

5.1.3.2 AC-Coupled non-HCSL Loads

The RC190CLK output can directly drive AC-coupling capacitors without any termination components. The clock input side of the AC-coupling capacitor may require an input-dependent bias network (BN). For examples of terminating the RC19xxx CLK outputs to other logic families such as LVDS, LVPECL, or CML, see [AN-891](#).

Figure 20 to Figure 22 show the various CLK output configurations.

5.2 Power Down Tolerant Pins

Pins that are Power Down Tolerant (PDT) can be driven by voltages as high as the normal VDD of the chip, even though VDD is not present (the device is not powered). There will be no ill effects to the device and it will power up normally. This feature supports disaggregation, where the RC19xxx may be on one circuit board and devices that interface with it are on other boards. These boards may power up at different times, driving pins on the RC19xxx before it has received power. [Figure 23](#) provides an example of a PDT call-out in a data sheet.

A4	CLKINb	I, DIF, PDT	Complementary clock input.
A5	CLKIN	I, DIF, PDT	True clock input.

Figure 23. Example: Power Down Tolerant Pin Descriptions

RC19xxx devices support Flexible Startup Sequencing (FSS). FSS allows application of CLKIN at different times in the device/system startup sequence. FSS is an additional feature that helps the system designer manage the impact of disaggregation. [Table 37](#) shows the supported sequences; that is, the RC19xxx devices can have CLKIN running before VDD is applied, and can have VDD applied and sit for extended periods with no input clock.

5.4 Loss of Signal and Automatic Clock Parking

The RC190 buffers and multiplexers have a Loss of Signal (LOS) circuit to detect the presence or absence of an input clock. The LOS circuit drives the open-drain LOSb pin (the “b” suffix indicates “bar”, or active-low) and sets the LOS_EVT bit in the SMBus register space. There are two slightly different LOSb pin behaviors at power up. [Figure 24](#) shows the LOSb de-assertion timing for the 4, 8, 13, 16 and 24-output buffers. CLKIN is represented differentially in [Figure 24](#) and [Figure 25](#).

Figure 24. LOSb De-assert Timing, RC19004, RC19008, RC1901x, RC19024

Note: The LOS circuit on the 4, 8, 13, 16, and 24 output buffers requires a CLKIN edge to release the LOSb pin after power up. So, the LOSb pin will be high until the first clock edge after power up.

Figure 25 shows the LOSb de-assertion timing for the 20-output buffers and all RC192xx clock multiplexers. LOSb on the 20-output buffers and all RC192xx multiplexers defaults to low at power up.

Figure 25. LOSb De-assert Timing RC19002, RC19020, RC192xx Devices

Note: The LOSb pin monitors the *selected input clock* in the RC192xx multiplexers.

The following diagram shows the LOSb assertion sequence when the CLKIN is lost. It also shows the Automatic Clock Parking (ACP) circuit bring the inputs to a Low/Low state after an LOS event. For exact timing, see [Electrical Specifications](#).

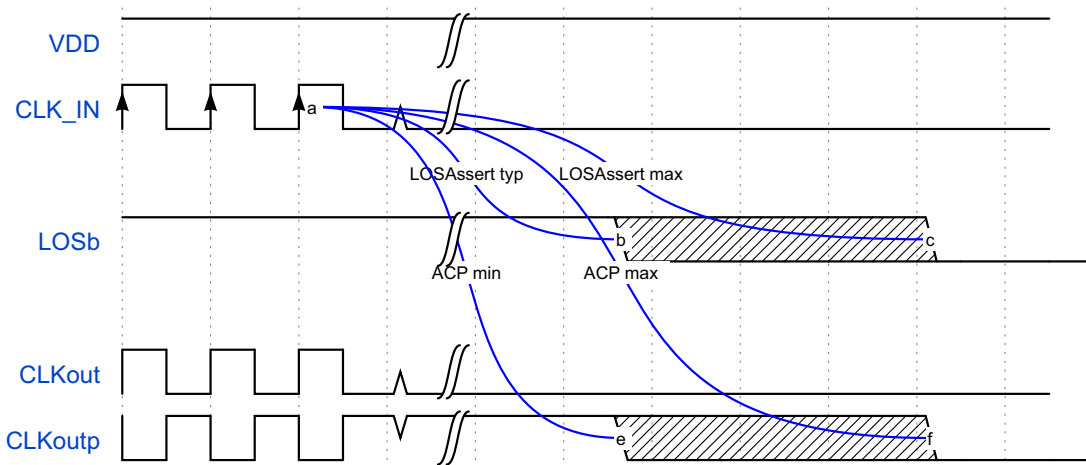

Figure 26. LOSb Assert Timing

5.5 Output Enable Control

The RC190 buffer/mux family provides three mechanisms to enable or disable clock outputs. All three mechanisms start and stop the output clocks in a synchronous, glitch-free manner. A clock output is enabled only when all three mechanisms indicate “enabled.” The following sections describe the three mechanisms.

5.5.1 SMBus Output Enable Bits

This section does not apply to the RC19002 because it does not have an SMBus.

The RC19xxx Clock buffer/multiplexer family has a traditional SMBus output enable bit for each output. The power-up default is 1, or enabled. Changing this bit to a 0 disables the output to a low/low state. The transitions between the enable and disable states are glitch-free in both directions.

Note: The glitch-free synchronization logic requires the CLKIN be running to enable or disable the outputs with this mechanism.

5.5.2 Output Enable (OEb) Pins

The OEb (Note: the “b” suffix indicates “bar”, or active-low) pins on the RC19xxx family provide flexible CLKREQb functionality for PCIe slots and/or banked OE control for ‘motherboard-down’ devices (depending on the device). If the OEb pin is low the controlled output is enabled. If the OEb pin is high, the controlled output is disabled to a low/low state. All OEb pins enable and disable the controlled outputs in a glitch-free, synchronous manner.

Note: The glitch-free synchronization logic requires the CLKIN be running to enable or disable the outputs with this mechanism.

5.5.3 RC19024/020 Clock Buffer OEb Pins

The 24-output RC19024 has three dedicated OEb pins (OE2b, OE22b, and OE23b) that control CLK [2,22,23], respectively. It also has four bank OEb pins, OEb[A:D], that are mappable. Each pin can control up to six clock outputs, and defaults to controlling one output. The RC19024 output enable mapping is described in [Table 38](#).

1. See the OEb_ASSIGNMENT registers in [Table 33](#).

The RC19020 and the RC19020A072 each have 8 OEb pins. Some of the pins are muxed with SBI functions.

The RC19020A072 OEb pins may be configured to control up to 2 outputs. Details are provided in [Table 39](#) and [Table 40](#).

The smaller RC19016, RC19013, and RC19004 devices (16, 13, and 4 outputs respectively) provide a dedicated OEB pin for each output, and therefore do not have OEB_ASSIGNMENT registers. Note that four OEB pins are used for the SBI interface when SBI_ENQ = 1 (for more information, see [Table 41](#)).

The RC19002 has single function dedicated OEB pins. For more information, see [Figure 9](#).

5.5.4 Side-Band Interface (SBI)

This section does not apply to the RC19002 because it does not have a side-band interface.

SMBus output enable bits and OEB pins are the traditional methods for enabling and disabling clocks. The 2-wire SMBus interface can enable or disable all clock outputs in a device. This pin efficiency is its advantage. The SMBus interface's main drawback is that it is a relatively slow physical interface, whose software is one of several routines running on an often overtaxed micro-controller. OEB pins are real-time and are ideally dedicated to an individual clock output. As buffers grow in output count, dedicated OEB pins become problematic for two reasons. First, the clock buffer pin count becomes much larger than it otherwise would be, resulting in a larger package. Second, unless the OEB pins are used for CLKREQ# functionality, the number of pins that need to be controlled outgrows the GPIO pins of an FPGA or micro-controller.

A third output enable/disable mechanism, the Side-Band Interface (SBI), addresses these issues. The SBI is a simple 3-wire (4-wire if the SBI_OUT pin is used) interface that can control all outputs across multiple devices. The SBI is only slightly less pin efficient than the SMBus, and is much more pin efficient than a dedicated OEB pins per output. It is protocol-free, hardware-oriented and runs at speeds up to 25MHz, much faster than SMBus.

Another SBI advantage is that it is active after power is applied and before PWRGD is asserted. External logic can disable specific outputs before PWRGD is asserted, and can then dynamically adjust the output run state during device operation. The SBI can make the adjustments much more rapidly than SMBus.

The RC19xxxA 4-wire SBI interface consists of the SBI_IN, SBI_CLK, SHFT_LDb, and SBI_OUT pins. The RC19xxxA SBI is enabled by strapping the SBI_ENQ pin to 1. When enabled, various OEB pins become the SBI interface. The exact pins that are multiplexed vary with device (for more information, see [Table 41](#)).

The SBI_ENQ pin strap takes effect as soon as power is applied and is not dependent on the assertion of PWRGD_PWRDNb to 1. Because of this, the SBI_ENQ must be static and cannot change once power is applied. If SBI_ENQ is 0 when power is applied, the SBI is disabled and has no impact on enabling or disabling outputs.

The SBI consists of a shift register, an SMBus readback register (of the shift register contents), and an SMBus MASK register. The SBI shifts a bit stream containing the enable/disable pattern into the shift register. A 1 enables an output and a 0 disables an output. All shift-register bits default to 1 at power up, indicating an enabled state. This means that the SBI can be used to disable outputs at power up because the default is enabled.

The SBI has its own SBI_CLK and does not need a running CLKIN to shift in an enable/disable pattern. This provides utmost flexibility for setting output run state before the SMBus becomes active or before the CLKIN is applied. When the SBI indicates enabled, the standard SMBus output enable bits and OEB pins can control the outputs.

The SBI feeds common output enable/disable synchronization logic ensuring glitch-free enable and disable of outputs. Note: The glitch-free synchronization logic requires the CLKIN be running to enable or disable the outputs with this mechanism.

If the application does not use the SBI, the SBI_ENQ pin can be tied to 0, and the entire SBI has no impact on enabling or disabling clock outputs.

The SBI Mask registers allow the user to block the disable function of the SBI via the SMBus. The SBI Mask registers default to 0 at power-up, allowing the SBI shift register bits to disable their respective output. After asserting the PWRGD_PWRDNb pin high, the SMBus is active and the SBI mask registers can be configured via SMBus to mask off (block) the SBI disable function. In other words, setting an SBI Mask bit to 1 forces the SBI to always indicate “enable” for the respective output. This allows the user to prevent the SBI from accidentally turning off a critical output.

The RC190xx clock buffers provide the ability to read back the SBI shift register contents via the SMBus. The SMBus readback values update on each falling edge of SHFT_LDb. Note: The SBI shift register can only be read using the SMBus; the SMBus *cannot* be used to load it.

Figure 27 shows the high-level functional description of SBI.

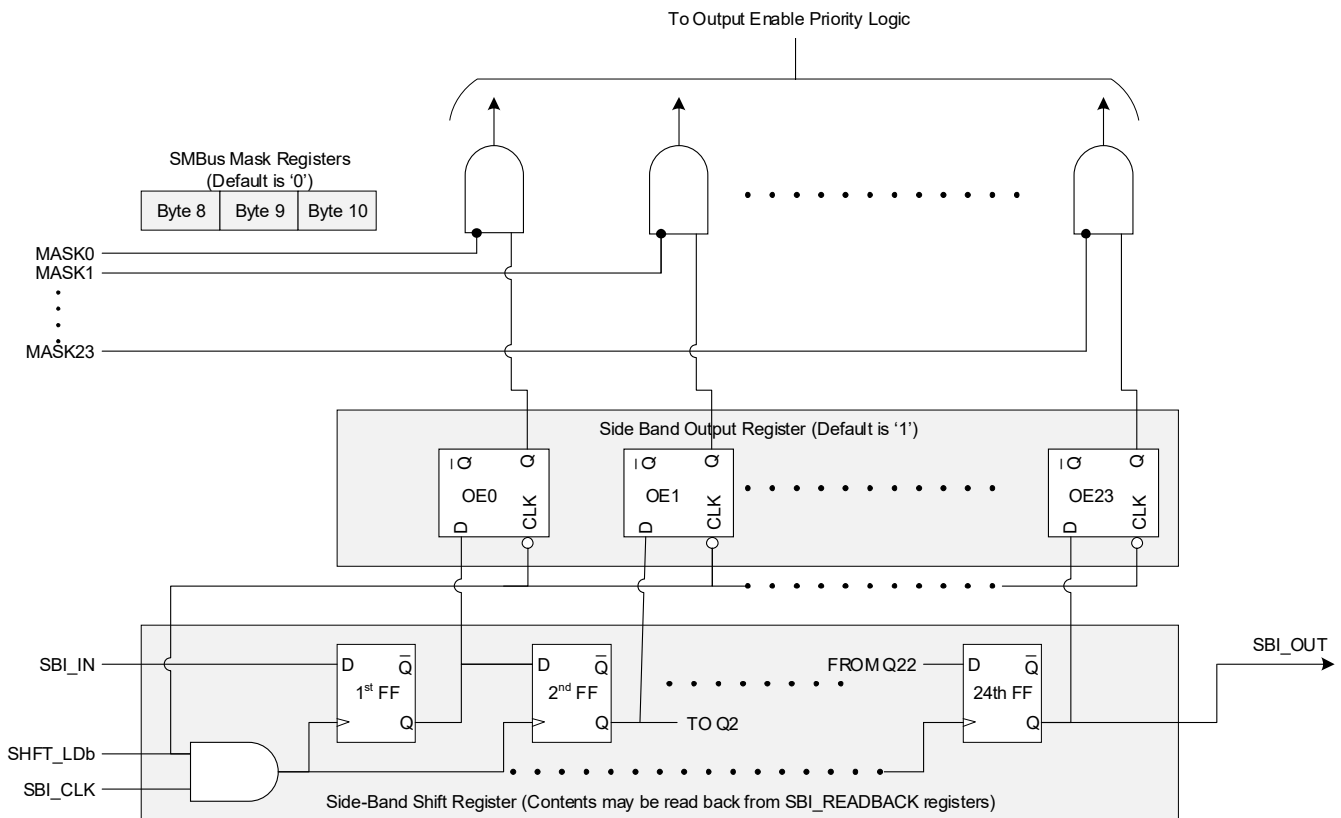

Figure 27. Side-band Interface High-Level Functional Diagram (RC19024 shown)

5.5.4.1 Using the SBI

Using the RC19024 as an example, we see the SBI shift order follows the order of the SMBus enable bits. in Byte [2:0] as shown in Figure 28. The first bit shifted in would be the output enable/disable bit for the CLK23, which is in Byte 2 bit 7. The last bit shifted in would be the output enable/disable for CLK0, which is in Byte 0, bit 0.

Figure 30 through Figure 33 show the Side-Band Shift Order for the RC19016, RC19013, RC19008, and RC19004 buffers. Notice that the Side-Band Shift Count is equal to the number of outputs in each device.

5.5.4.2 Side-Band Interface Timing

Figure 34 shows the basic timing of the side-band interface. The SHFT_LDb pin goes high to enable the SBI_CLK input. Next, the rising edge of SBI_CLK clocks SBI_IN data into the shift register. After the 24th clock (assuming the RC19024), stop the SBI_CLK low and drive the SHFT_LDB pin low. The falling edge of SHFT_LDb latches the shift register contents to the output control register, disabling or enabling the outputs. Always shift the complete set of bits into the shift register to control the outputs. For the Side-Band Interface AC/DC Electrical Characteristics, see Table 29.

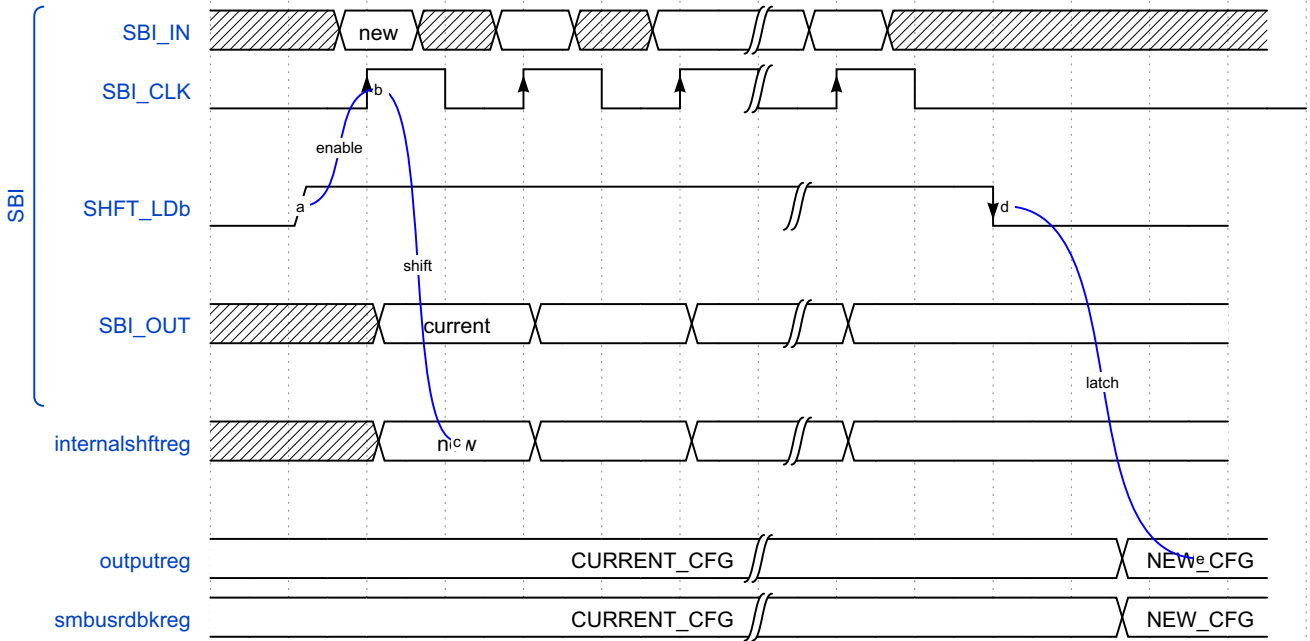

Figure 34. Side-Band Interface Functional Timing

5.5.4.3 Side-Band Interface Connection Topologies

The RC19xxxA buffer/mux devices support two SBI connection topologies: star and daisy chain. In a star topology, multiple devices can share the SBI_CLK and SBI_IN pins. In this topology, each RC190xx has a dedicated SHFT_LDb pin. In a daisy-chain topology, the SBI_OUT of one device connects to the SBI_IN of a downstream device. When using the daisy-chain topology, the user must shift a complete set of bits for the combined devices. Two daisy-chained RC19024 devices require shifting of $2 \times 24 = 48$ bits. An RC19016 followed by an RC19008 would require shifting $8 + 16 = 24$ bits. When the SHFT_LDb pin is low, the SBI interface ignores any activity on the SBI_CLK and SBI_IN pins.

Figure 35 shows a star topology connection for the RC19xxxA SBI interface. The star topology allows independent configuration of each device. For the RC19024, this means shifting 24 bits at a time. A disadvantage is that a separate SHFT_LDb pin is required for each device. The star topology allows additional devices to be controlled at the cost of an additional GPIO per device.

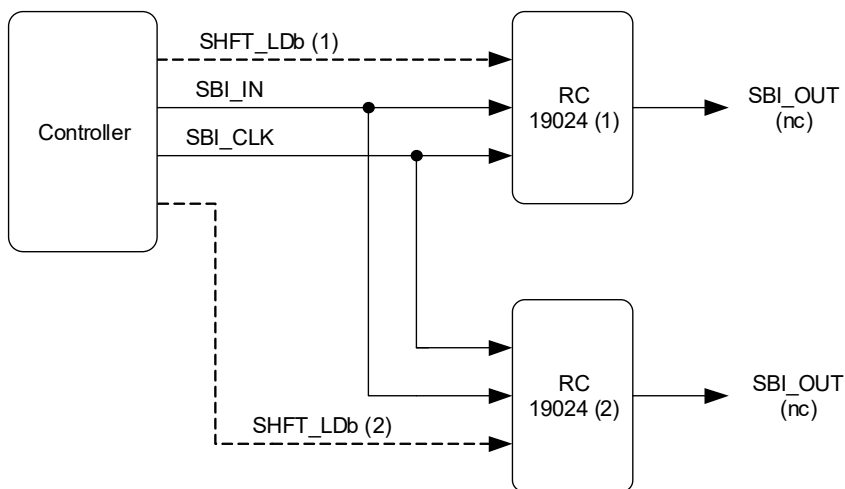

Figure 35. Side-Band Interface Star Topology

The daisy-chain topology allows configuration of any number of devices with only three signals from the SBI controller. It uses the SBI_OUT pin of one device to drive the SBI_IN pin of the next device in the daisy chain. Users must take care to shift the proper number of bits in this configuration. For the example shown in [Figure 36](#), the SBI bit stream consists of 48 bits.

Figure 36. Side-Band Interface Daisy-Chain Topology

5.5.5 Output Enable/Disable Priority

The RC190 output enable/disable priority is an “AND” function of all enable methods. This means that the SMBus output enable bit AND the OEB pin (if present/assigned) AND the SBI must indicate that the output is enabled in order for the output to be enabled. A logical representation of the priority logic is shown in [Figure 37](#).

9. Revision History

Revision	Date	Description
1.14	Jun 29, 2023	<ul style="list-style-type: none"> ▪ Updated RC19002 Pin Information for pins 3, 6, 7, and 8. ▪ Updated various device specifications: <ul style="list-style-type: none"> • V_{MAX}, V_{MIN}, V_{LOW}, and $\Delta T_{R/F}$ in Table 17 • V_{OL} and t_{DC} in Table 18 • V_{OH}, V_{OL}, V_{CROSS}, and ΔV_{CROSS}, t_F in Table 19 • V_{OH}, V_{CROSS}, t_R, and t_{DC} in Table 20 • V_{OL}, V_{CROSS}, ΔV_{CROSS}, ΔV_{CROSS}, and t_R in Table 21 • V_{OH}, V_{OL}, V_{CROSS}, ΔV_{CROSS}, t_R, t_F in Table 22 • Added V_{DDCLK} Operating Current 100Ω impedance values for RC19002 in Table 25 ▪ Completed other minor changes
1.13	Jun 2, 2023	<ul style="list-style-type: none"> ▪ Added missing slew rate control bytes 20 and 21 to Table 36 ▪ Renamed various tables to list the parts they apply to instead of using "x" wildcard. ▪ Removed "A" suffix from generic part number references through out the document; left A100 and A072 suffixes.
1.12	May 10, 2023	<ul style="list-style-type: none"> ▪ Updated the Type information for OEb pins in Pin Information ▪ Updated the Applications Information ▪ Completed other minor changes
1.11	Mar 10, 2023	<ul style="list-style-type: none"> ▪ Added RC19002A to data sheet, moved back to Preliminary pending production release of the RC19002A.
1.10	Dec 1, 2022	<ul style="list-style-type: none"> ▪ Fixed the link for the 40-VFQFPN package in Table 42.
1.09	Nov 17, 2022	<ul style="list-style-type: none"> ▪ Changed t_{SLEW} to 6 from 4 in Table 29.
1.08	Nov 15, 2022	<ul style="list-style-type: none"> ▪ Updated the description of RC19024 pin A7 in Table 1
1.07	Apr 11, 2022	<ul style="list-style-type: none"> ▪ For all devices <i>except</i> RC19020A072: <ul style="list-style-type: none"> • Updated Pin Type of all pins beginning with OEb to properly indicate internal pull-down (PD) resistors. ▪ For all devices <i>except</i> RC19020A072 and RC19024A: <ul style="list-style-type: none"> • Removed Power-Down Tolerant indicator from multiplexed OEb SBI_OUT pins, they are not PDT. ▪ Minor reformatting of Pin Descriptions to reduce required space in Pin Description tables and to provide consistency across devices.
1.06	Apr 4, 2022	<ul style="list-style-type: none"> ▪ Updated Loss of Signal and Automatic Clock Parking to change all CLK_IN to CLKIN for consistency. ▪ Inserted LOSb De-assert Timing RC19002, RC19020, RC192xx Devices figure to distinguish the LOSb start-up behavior of those devices from the other devices.
1.05	Mar 23, 2022	Updated pins B10 and B43 from Do Not Connect (DNC) to GND on RC19024 Pin Assignments to tie off floating pins used for test.
1.04	Mar 15, 2022	Updated the <i>PCI Express Base Specification 6.0</i> revision reference to 1.0 in footnotes 1 and 7 in Table 9 and Table 10 .
1.03	Mar 3, 2022	<ul style="list-style-type: none"> ▪ Corrected pin 10 of RC19008A from NC to VDDCLK (see RC19008 Pin Assignments).
1.02	Feb 24, 2022	<ul style="list-style-type: none"> ▪ Completed minor updates to titles of CLK AC/DC Characteristics Tables for clarity. ▪ Completed other minor changes

Revision	Date	Description
1.01	Feb 01, 2022	<ul style="list-style-type: none">▪ Added RC19020A072 pin out and pin descriptions to data sheet.▪ Updated Figure 10 for RC19020A and RC19020A072.▪ Updated Figure 2 title to reference correct package type (VFQFPN) and updated “100-GQFN” references to “100-VFQFPN” throughout the document.▪ Added RC19020A072 marking diagram to RC1902xA Marking Diagrams and updated marking descriptions of RC19020A and RC19020A072.
1.00	Jan 18, 2022	Initial release.

NOTES:

1. ALL DIMENSIONS AND TOLERANCES ARE PER ASME Y14.5M-1994.
2. ALL DIMENSIONS ARE IN MILLIMETERS.
