## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## General Description

The MAX20028 power-management integrated circuit (PMIC) is a 2.1 MHz , multichannel, DC-DC converter designed for automotive applications. The device integrates three supplies in a small footprint. The device includes one high-voltage step-down controller (OUT1), designed to run directly from a car battery, and two lowvoltage step-down converters (OUT2/OUT3), cascaded from OUT1. Under no-load conditions, the MAX20028 consumes only $30 \mu \mathrm{~A}$ of quiescent current, making it ideal for automotive applications.

The high-voltage synchronous step-down DC-DC controller (OUT1) operates from a voltage up to 36 V continuous and is protected from load-dump transients up to 42 V . There is a pin-selectable frequency option of either 2.1 MHz or a factoryset frequency for $1.05 \mathrm{MHz}, 525 \mathrm{kHz}, 420 \mathrm{kHz}$, or 350 kHz . The low-voltage, synchronous step-down DC-DC converters run directly from OUT1 and can supply output currents up to 3A. The device provides a spread-spectrum enable input (SSEN) to provide quick improvement in electromagnetic interference when needed. There is also a SYNC I/O for providing either an input to synchronize to an external clock source or an output of the internally generated clock (see the Selector Guide for the different options available). The device includes overtemperature shutdown and overcurrent limiting. The device also includes individual RESET1 outputs and individual enable inputs. The individual RESET1 outputs provide voltage monitoring for all output channels.
The MAX20028 is available in a 32 -pin ( $5 \mathrm{~mm} \times 5 \mathrm{~mm} \times$ 0.75 mm ) side-wettable TQFN-EP package and is specified for operation over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ automotive temperature range.

## Applications

- Automotive
- Industrial
- ADAS

## Ordering Information and Selector Guide appear at end of data sheet.

## Benefits and Features

- High-Efficiency Voltage DC-DC Controller Saves Power
- 3.5 V to 36 V Operating Supply Voltage
- Output Voltage: Pin Selectable, Fixed, or Resistor-Divider Adjustable
- 350 kHz to 2.1 MHz Operation
- $30 \mu \mathrm{~A}$ Quiescent Current with DC-DC Controller Enabled
- Dual 2.1MHz DC-DC Converters with Integrated FETs Saves Space
- OUT2 and OUT3 are Cascaded from OUT1, Improving Efficiency
- 3A Output Current
- 0.8 V to 3.95 V Output Voltage
- $25 \%$ Lower COUT2 and COUT3 Compared to the MAX16993
- Fixed or Resistor-Divider-Adjustable Output Voltage
- $180^{\circ}$ Out-of-Phase Operation
- High Accuracy to Meet ASIL Specification
- $\pm 1 \%$ FB Accuracy, $\pm 2 \%$ Output-Voltage Accuracy, and $\pm 0.5 \%$ OV/UV Accuracy
- Excellent Load-Transient Performance
- Robust for the Automotive Environment
- Current-Mode Architecture with Forced-PWM and Skip Modes of Operations
- Frequency Synchronization Input/Output Reduces System Noise
- Individual Enable Inputs and RESET1 Outputs
- Overtemperature and Short-Circuit Protection
- AECQ-100 Qualified

## Simplified Schematic

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

| Absolute Maximum Ratings |  |
| :---: | :---: |
| $V_{\text {SUP }}$, EN1 to GND | . 0.3 V to +45 V |
| PV to GND. | -0.3V to +6.0V |
| PV1 to GND. | -0.3V to +6.0V |
| PV2 to GND, PV2 to PGND2. | -0.3V to +6.0V |
| PV3 to GND, PV3 to PGND3. | -0.3V to +6.0V |
| PGND2, PGND3 to GND | . 0.3 V to +0.3 V |
| LX1 to GND | -6.0V to $\mathrm{V}_{\text {SUP }}+6.0 \mathrm{~V}$ |
| BST1 to LX1 | ..-0.3V to +6.0V |
| DH1 to LX1 | -0.3V to BST1 + 0.3V |
| BIAS to GND | ...-0.3V to +6.0V |
| DL1 to GND. | -0.3V to PV1 + 0.3V |
| LX2 to PGND2 | -0.3V to PV2 + 0.3V |
| LX3 to PGND3. | -0.3V to PV3 + 0.3V |
| OUT1-OUT3, CS1 to GND | .......-0.3V to +6.0V |

FB1, EN2, EN3 to GND.......................................-0.3V to +6.0 V
RESET_, ERR to GND..........................................-0.3V to +6.0 V
CS1 to OUT1........................................................ 0.3 V to +0.3 V
CSEL1, SYNC, SSEN to GND .............................-0.3V to +6.0 V
COMP1 to GND............................................-0.3V to PV + 0.3V
LX2, LX3 Output Short-Circuit Duration....................Continuous
Continuous Power Dissipation ( $\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}$ )
TQFN (derate $34.5 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )............... 2758.6 mW
Operating Temperature Range.......................... $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Junction Temperature ..................................................... $+150^{\circ} \mathrm{C}$
Storage Temperature Range ............................. $65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Lead Temperature (soldering, 10s) ................................. $+300^{\circ} \mathrm{C}$
Soldering Temperature (reflow) ....................................... $+260^{\circ} \mathrm{C}$

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Package Thermal Characteristics (Note 1)

TQFN
Junction-to-Ambient Thermal Resistance ( $\theta_{\mathrm{JA}}$ ) ......... $29^{\circ} \mathrm{C} / \mathrm{W}$
Junction-to-Case Thermal Resistance ( $\theta_{\mathrm{JC}}$ )............ $1.7^{\circ} \mathrm{C} / \mathrm{W}$
Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

## Electrical Characteristics

$\left(V_{S U P}=14 \mathrm{~V}, \mathrm{~V}_{\mathrm{PV}}=\mathrm{V}_{\mathrm{PV} 1}=\mathrm{V}_{\mathrm{BIAS}}, \mathrm{V}_{\mathrm{PV} 2}=\mathrm{V}_{\mathrm{PV} 3}=\mathrm{V}_{\mathrm{OUT} 1} ; \mathrm{T}_{\mathrm{A}}=\mathrm{T}_{\mathrm{J}}=-40^{\circ} \mathrm{C}\right.$ to $+125^{\circ} \mathrm{C}$, unless otherwise noted. Typical values are at $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$ under normal conditions, unless otherwise noted.) (Note 2)

| PARAMETER | SYMBOL | CONDITIONS | MIN | TYP | MAX | UNITS |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Pin Configuration

## Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | PV1 | Supply Input for Buck 1 Low-Side Gate Drive. Connect a ceramic bypass capacitor of at least $0.1 \mu \mathrm{~F}$ from PV1 to GND. |
| 2 | DL1 | Low-Side Gate-Drive Output for Buck 1. DL1 output voltage swings from $\mathrm{V}_{\mathrm{GND}}$ to $\mathrm{V}_{\mathrm{PV} 1}$. |
| 3 | GND | Power Ground for Buck 1 |
| 4 | LX1 | Inductor Connection for Buck 1. Connect LX1 to the switched side of the inductor. LX1 serves as the lower supply rail for the DH1 high-side gate drive. |
| 5 | DH1 | High-Side Gate-Drive Output for Buck 1. DH1 output voltage swings from $\mathrm{V}_{\mathrm{LX} 1}$ to $\mathrm{V}_{\mathrm{BST} 1}$ - |
| 6 | BST1 | Bootstrap Capacitor Connection for High-Side Gate Drive of Buck 1. Connect a high-voltage diode between BIAS and BST1. Connect a ceramic capacitor between BST1 and LX1. See the High-Side GateDrive Supply (BST1) section. |
| 7 | $\mathrm{V}_{\text {SUP }}$ | Supply Input. Bypass $\mathrm{V}_{\text {SUP }}$ with a minimum $0.1 \mu \mathrm{~F}$ capacitor as close as possible to the device. |
| 8 | EN1 | High-Voltage Tolerant, Active-High Digital Enable Input for Buck 1. Driving EN1 high enables Buck 1. |
| 9 | BIAS | 5 V Internal Linear Regulator Output. Bypass BIAS to GND with a low-ESR ceramic capacitor of $2.2 \mu \mathrm{~F}$ minimum value. BIAS provides the power to the internal circuitry. See the Linear Regulator (BIAS) section. |
| 10 | PV | Analog Supply. Connect PV to BIAS through a $10 \Omega$ resistor and connect a $1 \mu \mathrm{~F}$ ceramic capacitor from PV to ground. |
| 11 | FB1 | Feedback Input for Buck 1. For the fixed output-voltage option, connect FB1 to BIAS for the factorytrimmed ( 3.0 V to 3.75 V or 4.6 V to 5.35 V ) fixed output. Connect FB1 to GND for the 3.3 V fixed output. For the resistor-divider-adjustable output-voltage option, connect FB1 to a resistive divider between OUT1 and GND to adjust the output voltage between 3.0 V and 5.5 V . In adjustable mode, FB1 regulates to 1.0 V (typ). See the OUT1 Adjustable Output-Voltage Option section. |

## Pin Description (continued)

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 12 | CS1 | Positive Current-Sense Input for Buck 1. Connect CS1 to the positive terminal of the current-sense resistor. See the Current-Limit/Short-Circuit Protection and Current-Sense Measurement sections. |
| 13 | OUT1 | Output Sense and Negative Current-Sense Input for Buck 1. The buck uses OUT1 to sense the output voltage. Connect OUT1 to the negative terminal of the current-sense resistor. See the Current-Limit/ShortCircuit Protection and Current-Sense Measurement sections. |
| 14 | EN2 | Active-High Digital Enable Input for Buck 2. Driving EN2 high enables Buck 2. |
| 15 | EN3 | Active-High Digital Enable Input for Buck 3. Driving EN3 high enables Buck 3. |
| 16 | OUT3 | Buck Converter 3 Voltage-Sense Input. Connect OUT3 to the output of Buck 3. Connect OUT3 to an external feedback divider when setting DC-DC3 voltage externally. See the OUT2/OUT3 Adjustable Output-Voltage Option section. |
| 17 | RESET3 | Open-Drain Buck 3 Reset Output. $\overline{\text { RESET3 }}$ remains low for a fixed time after the output of Buck 3 has reached its regulation level (see the Selector Guide). To obtain a logic signal, pull up RESET3 with an external resistor connected to a positive voltage lower than 5 V . |
| 18 | PV3 | Buck 3 Voltage Input. Connect a $2.2 \mu \mathrm{~F}$ or larger ceramic capacitor from PV3 to PGND3. Connect PV3 to OUT1. |
| 19 | LX3 | Buck 3 Switching Node. LX3 is high impedance when the device is off. |
| 20 | PGND3 | Power Ground for Buck 3 |
| 21 | PGND2 | Power Ground for Buck 2 |
| 22 | LX2 | Buck 2 Switching Node. LX2 is high impedance when the device is off. |
| 23 | PV2 | Buck 2 Voltage Input. Connect a $2.2 \mu \mathrm{~F}$ or larger ceramic capacitor from PV2 to PGND2. Connect PV2 to OUT1. |
| 24 | RESET2 | Open-Drain Buck 2 Reset Output. $\overline{\text { RESET2 }}$ remains low for a fixed time after the output of Buck 2 has reached its regulation level (see the Selector Guide). To obtain a logic signal, pull up $\overline{\text { RESET2 }}$ with an external resistor connected to a positive voltage lower than 5 V . |
| 25 | OUT2 | Buck Converter 2 Voltage-Sense Input. Connect OUT2 to the output of Buck 2. Connect OUT2 to an external feedback divider when setting DC-DC2 voltage externally. See the OUT2/OUT3 Adjustable Output-Voltage Option section. |
| 26 | CSEL1 | Buck 1 Clock Select. Connect CSEL1 to GND for 2.1 MHz operation. Connect CSEL1 to BIAS for an OTPprogrammable divide-down operation. See the Selector Guide for the fSW1 divide ratio. |
| 27 | SSEN | Spread-Spectrum Enable. Connect SSEN to GND for standard oscillator operation. Connect SSEN to BIAS to enable the spread-spectrum oscillator. |
| 28 | RESET1 | Open-Drain Buck 1 Reset Output. $\overline{\text { RESET1 }}$ remains low for a fixed time after the output of Buck 1 has reached its regulation level (see the Selector Guide). To obtain a logic signal, pull up RESET1 with an external resistor connected to an appropriate voltage. |
| 29 | GND | Analog Ground |
| 30 | COMP1 | Compensation for Buck 1. See the Compensation Network section. |
| 31 | ERR | Open-Drain Error-Status Output. $\overline{\mathrm{ERR}}$ signals a thermal-warning/shutdown condition. To obtain a logic signal, pull up $\overline{E R R}$ with an external resistor connected to a positive voltage lower than 5 V . |
| 32 | SYNC | Synchronization Input/Output. SYNC allows the device to synchronize to other supplies. Connect SYNC to GND or leave unconnected to enable skip-mode operation under light loads. Connect SYNC to BIAS or an external clock to enable fixed-frequency forced-PWM-mode operation. When configured as an output, SYNC outputs the internally generated 2.1 MHz clock. |
| - | EP | Exposed Pad. Connect the exposed pad to ground. Connecting the exposed pad to ground does not remove the requirement for proper ground connections to PGND2-PGND3 and GND. The exposed pad is attached with epoxy to the substrate of the die, making it an excellent path to remove heat from the IC. |

## Typical Operating Circuit

## MAX20028

## Detailed Description

The MAX20028 PMIC is a 2.1 MHz , multichannel, DC-DC converter designed for automotive applications. The device includes one high-voltage step-down controller (OUT1) designed to run directly from a car battery, and two low-voltage step-down converters (OUT2/OUT3) cascaded from OUT1.
The 2.1 MHz , high-voltage buck controller operates with a 3.5 V to 36 V input voltage range and is protected from load-dump transients up to 42 V . The high-frequency operation eliminates AM band interference and reduces the solution footprint. It can provide an output voltage between 3.0 V and 5.5 V set at the factory or with external resistors. The device has two pin-selectable frequency options, 2.1 MHz or a lower frequency based on the factory setting. Available factory-set frequencies are $1.05 \mathrm{MHz}, 525 \mathrm{kHz}, 420 \mathrm{kHz}$, or 350 kHz . Under no-load conditions, the device consumes only $30 \mu \mathrm{~A}$ of quiescent current with OUT1 enabled.

The dual buck converters can deliver 1.5 A or 3.0 A of load current per output. They operate directly from OUT1 and provide 0.8 V to 3.95 V output voltage range. Factorytrimmed output voltages achieve $\pm 1.8 \%$ output voltage over load, line, and temperature without using expensive $\pm 0.1 \%$ resistors. In addition, adjustable output-voltage versions can be set to any desired values between 0.8 V and 3.6V using an external resistive divider. On-board low $R_{D S(O N)}$ switches help minimize efficiency losses at heavy loads and reduce critical/parasitic inductance, making the layout a much simpler task with respect to discrete solutions. Following a simple layout and footprint ensures first-pass success in new designs (see the $\underline{P C B}$ Layout Guidelines section).
The device features either a SYNC input or a SYNC output (see the Synchronization Input/Output (SYNC) section and the Selector Guide). Optional spread-spectrum frequency modulation minimizes radiated electromagnetic emissions due to the switching frequency; factoryprogrammable synchronization I/O (SYNC) allows better noise immunity. Additional features include 4 ms fixed soft-start for OUT1 and 2.5 ms for OUT2/OUT3, individual RESET_outputs, and overcurrent/overtemperature protections. See the Selector Guide for the available options.

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## Enable Inputs (EN1-EN3)

All three regulators have their own enable input. When EN1 exceeds the EN1 high threshold, the internal linear regulator is switched on. When VSUP exceeds the VSUP,STARTUP threshold, Buck 1 is enabled and OUT1 starts to ramp up with a 4 ms soft-start. Once the Buck 1 soft-start is complete, Buck 2 and Buck 3 can be enabled. When either Buck 2 or Buck 3 is enabled, the corresponding output ramps up with a 2.5 ms soft-start. When an enable input is pulled low, the converter is switched off and the corresponding OUT_ and RESET_ are driven low. If EN1 is low, all regulators are disabled.

## Reset Outputs ( $\overline{\text { RESET1 }}-\overline{\text { RESET3 }})$

The device features individual open-drain $\overline{\text { RESET_}_{-}}$ outputs for each buck output that asserts when the buck output voltage drops 6\% below the regulated voltage. RESET_remains asserted for a fixed timeout period after the buck output rises up to its regulated voltage. The fixed timeout period is programmable between 0.1 ms and 7.4 ms (see the Selector Guide). To obtain a logic signal, pull up $\overline{R E S E T}$ _ with an external resistor connected to a positive voltage lower than 5 V .

## Linear Regulator (BIAS)

The device features a 5V internal linear regulator (BIAS). Connect BIAS to PV, which acts as a supply for internal circuitry. Also connect BIAS to PV1, which acts as a supply for the low-side gate driver of Buck 1. Bypass BIAS with a $2.2 \mu \mathrm{~F}$ or larger ceramic capacitor as close as possible to the device. BIAS can provide up to 125 mA (max), but is not designed to supply external loads.
After OUT1 completes soft-start, and depending on the OUT1 voltage setting, BIAS LDO can be turned off with the BIAS pin internally shorted to the OUT1 pin to power up internal circuits and provide gate drive for the Buck 1 low-side FET. This BIAS switchover is allowed for internally set OUT1 voltages above 4.2V (both in FPWM and skip modes of operation), and for internally set OUT1 voltages below 4.2 V when in skip mode of operation. BIAS switchover is not allowed if external divider option is used for OUT1.

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## Internal Oscillator

## Buck 1 Clock Select (CSEL1)

The device offers a Buck 1 clock-select input. Connect CSEL1 to GND for 2.1 MHz operation. Connect CSEL1 to BIAS to divide down the Buck 1 clock frequency by $2,4,5$, or 6 (see the Selector Guide). Buck 2 and Buck 3 switch at 2.1 MHz (typ) and are not controlled by CSEL1.

## Spread-Spectrum Enable (SSEN)

The device features a spread-spectrum enable (SSEN) input that can quickly enable spread-spectrum operation to reduce radiated emissions. Connect SSEN to BIAS to enable the spread-spectrum oscillator. Connect SSEN to GND for standard oscillator operation. When spread spectrum is enabled, the internal oscillator frequency is varied between fSW and (fsw $+6 \%$ ). The change in frequency has a sawtooth shape and a frequency of 4 kHz (see Figure 1). This function does not apply to externally applied oscillation frequency. See the Selector Guide for available options.

## Synchronization Input/Output (SYNC)

SYNC is factory-programmable I/O. See the Selector Guide for available options. When configured as an input, a logic-high on SYNC enables fixed-frequency, forcedPWM mode. Apply an external clock on the SYNC input to synchronize the internal oscillator to an external clock. The SYNC input accepts signal frequencies in the range of $1.7 \mathrm{MHz}<$ fSYNC $<2.4 \mathrm{MHz}$. The external clock should have a duty cycle of $50 \%$. A logic-low at the SYNC input enables the device to enter a low-power skip mode under
light-load conditions. When configured as an output, SYNC outputs the internally generated 2.1 MHz clock that switches from $\mathrm{V}_{\mathrm{PV}}$ to $\mathrm{V}_{\mathrm{GND}}$. All converters operate in forced-PWM mode when SYNC is configured as an output.

## Common Protection Features

## Undervoltage Lockout

The device offers an undervoltage-lockout feature. Undervoltage detection is performed on the PV input. If $V_{\text {SUP }}$ decreases to the point where Buck 1 is in dropout, PV begins to decrease. If PV falls below the UVLO threshold (2.7V, typ), all three converters switch off and the $\overline{R E S E T}$ _ outputs assert low. Once the device has been switched off, $\mathrm{V}_{\text {SUP }}$ must exceed the $\mathrm{V}_{\text {SUP,STARTUP }}$ threshold before Buck 1 turns back on.

## Output Overvoltage Protection

The device features overvoltage protection on the buck converter outputs. If the FB1 input exceeds the output overvoltage threshold, a discharge current is switched on at OUT1 and RESET1 asserts low.

## Soft-Start

The device includes a 4 ms fixed soft-start time on OUT1 and 2.5 ms fixed soft-start time on OUT2/OUT3. Soft-start time limits startup inrush current by forcing the output voltage to ramp up towards its regulation point. If OUT1 is prebiased above 1.25 V , all three buck converters do not start up until the prebias has been removed. Once the prebias has been removed, OUT1 self-discharges to GND and then goes into soft-start.

Figure 1. Effect of Spread Spectrum on Internal Oscillator

## MAX20028

## Thermal Warning and Overtemperature Protection

The device features an open-drain, thermal-warning indicator ( $\overline{\mathrm{ERR}}$ ). $\overline{\mathrm{ERR}}$ asserts low when the junction temperature exceeds $+145^{\circ} \mathrm{C}$ (typ). For a logic signal, connect a pullup resistor from ERR to a supply less than or equal to 5 V . When the junction temperature exceeds $+170^{\circ} \mathrm{C}$ (typ), an internal thermal sensor shuts down the buck converters, allowing the device to cool. The thermal sensor turns the device on again after the junction temperature cools by $30^{\circ} \mathrm{C}$ (typ).

## Buck 1 (OUT1)

Buck controller 1 uses a PWM current-mode-control scheme. An internal transconductance amplifier establishes an integrated error voltage. The heart of the PWM controller is an open-loop comparator that compares the integrated voltage-feedback signal against the amplified current-sense signal plus the slopecompensation ramp, which are summed into the main PWM comparator to preserve inner-loop stability and eliminate inductor staircasing. At each rising edge of the internal clock, the high-side MOSFET turns on until the PWM comparator trips or the maximum duty cycle is reached, or the peak current limit is reached. During this on-time, current ramps up through the inductor, storing energy in a magnetic field and sourcing current to the output. The current-mode feedback system regulates the peak inductor current as a function of the outputvoltage error signal. The circuit acts as a switch-mode transconductance amplifier and pushes the output LC filter pole normally found in a voltage-mode PWM to a higher frequency.
During the second half of the cycle, the high-side MOSFET turns off and the low-side MOSFET turns on. The inductor releases the stored energy as the current ramps down, providing current to the output. The output capacitor stores charge when the inductor current exceeds the required load current and discharges when the inductor current is lower, smoothing the voltage across the load. Under soft-overload conditions, when the peak inductor current exceeds the selected current limit (see the Current-Limit/Short-Circuit Protection section), the high-side MOSFET is turned off immediately and the low-side MOSFET is turned on and remains on to let the inductor current ramp down until the next clock cycle.

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## PWM/Skip Modes

The device features a synchronization input that puts all the buck regulators either in skip mode or forced-PWM mode of operation (see the Synchronization Input/Output (SYNC) section). In PWM mode of operation, the regulator switches at a constant frequency with variable on-time. In skip mode of operation, the regulator's switching frequency is load dependent until the output load reaches a certain threshold. At higher load current, the switching frequency does not change and the operating mode is similar to the PWM mode. Skip mode helps improve efficiency in light-load applications by allowing the regulator to turn on the high-side switch only when the output voltage falls below a set threshold. As such, the regulator does not switch MOSFETs on and off as often as is the case in PWM mode. Consequently, the gate charge and switching losses are much lower in skip mode.

## Minimum On-Time and Duty Cycle

The high-side gate driver for Buck 1 has a minimum ontime of 30 ns (typ). This helps ensure no skipped pulses when operating the device in PWM mode at 2.1 MHz with supply voltage up to 36 V and output voltage down to 3.3 V (see the Electrical Characteristics table).

## Current-Limit/Short-Circuit Protection

OUT1 offers a current-limit feature that protects Buck 1 against short-circuit and overload conditions on the buck controller. Buck 1 offers a current-limit sense input (CS1). Place a sense resistor in the path of the channel 1 current flow. Connect CS1 to the high side of the sense resistor and OUT1 to the low side of the sense resistor. Currentlimit protection activates once the voltage across the sense resistor increases above the 120 mV (typ) currentlimit threshold. In the event of a short-circuit or overload condition, the high-side MOSFET remains on until the inductor current reaches the current-limit threshold. The converter then turns on the low-side MOSFET and the inductor current ramps down. The converter allows the high-side MOSFET to turn on only when the voltage across the current-sense resistor ramps down to below 120 mV (typ). This cycle repeats until the short or overload condition is removed.

## Step-Down Controller with Dual 2.1 MHz

 Step-Down DC-DC Converters

Figure 2. Current-Sense Configuration

## Current-Sense Measurement

For the best current-sense accuracy and overcurrent protection, use a $1 \%$ tolerance current-sense resistor between the inductor and output, as shown in Figure 2. This configuration constantly monitors the inductor current, allowing accurate current-limit protection. Use low-inductance current-sense resistors for accurate measurement.

## High-Side Gate-Drive Supply (BST1)

The high-side MOSFET is turned on by closing an internal switch between BST1 and DH1 and transferring the bootstrap capacitor's charge (at BST1) to the gate of the high-side MOSFET. This charge refreshes when the high-side MOSFET turns off and the LX1 voltage drops down to ground potential, taking the negative terminal of the capacitor to the same potential. At this time, the bootstrap diode recharges the positive terminal of the bootstrap capacitor. The selected n-channel high-side MOSFET determines the appropriate boost capacitance values ( $\mathrm{C}_{\mathrm{BST} 1}$ in the Typical Operating Circuit) according to the following equation:

$$
\mathrm{C}_{\mathrm{BST} 1}=\frac{\mathrm{Q}_{\mathrm{G}}}{\Delta \mathrm{~V}_{\mathrm{BST} 1}}
$$

where $Q_{G}$ is the total gate charge of the high-side MOSFET and $\Delta \mathrm{V}_{\mathrm{BST}} 1$ is the voltage variation allowed on the high-side MOSFET driver after turn-on. Choose $\Delta \mathrm{V}_{\mathrm{BST}}$ such that the available gate-drive voltage is
not significantly degraded (e.g., $\Delta \mathrm{V}_{\mathrm{BST}}=100 \mathrm{mV}$ to 300 mV ) when determining $\mathrm{C}_{\text {BST1 }}$. Use a Schottky diode when efficiency is most important, as this maximizes the gate-drive voltage. If the quiescent current at high temperature is important, a low-leakage switching diode should be used.
The boost capacitor should be a low-ESR ceramic capacitor. A minimum value of 100 nF works in most cases. A minimum value of 470 nF is recommended when using a Schottky diode.

## Dropout

When OUT1 input voltage is lower than the desired output voltage, the converter is in dropout mode. Buck 1 continuously draws current from the bootstrap capacitor when the high-side switch is on. Therefore, the bootstrap capacitor needs to be refreshed periodically. When in dropout, the Buck 1 high-side gate drive shuts off every $8 \mu \mathrm{~s}$, at which point the low-side gate drive turns on for 120ns.

## Buck 2 and Buck 3 (OUT2 and OUT3)

Buck converters 2 and 3 are high-efficiency, low-voltage converters with integrated FETs. They use a PWM current-mode-control scheme operated at 2.1 MHz to optimize component size and efficiency, while eliminating AM band intererence. The buck converters can be configured to deliver 1.5A or 3.0A per channel. They operate directly from OUT1 and have either fixed or resistor-programmable output voltages that range from 0.8 V to 3.95 V (see the Selector Guide). Buck 2 and Buck 3 feature low on-resistance internal FETs that contribute to high efficiency and smaller system cost and board space. Integration of the p-channel high-side FET enables both channels to operate with $100 \%$ duty cycle when the input voltage falls to near the output voltage. They feature a programmable active timeout period (see the Selector Guide) that adds a fixed delay before the corresponding $\overline{R E S E T}$ _ can go high.

## FPWM/Skip Modes

The device features a synchronization input (SYNC) that puts the converter either in skip mode or forced-PWM (FPWM) mode of operation. See the Internal Oscillator section. In FPWM mode, the converter switches at a constant frequency with variable on-time. In skip mode, the converter's switching frequency is load-dependent until the output load reaches a certain threshold. At higher load current, the switching frequency does not change and the operating mode is similar to the FPWM mode.

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

Skip mode helps improve efficiency in light-load applications by allowing the converters to turn on the high-side switch only when the output voltage falls below a set threshold. As such, the converter does not switch MOSFETs on and off, as often is the case in FPWM mode. Consequently, the gate charge and switching losses are much lower in skip mode.

## Current-Limit/Short-Circuit Protection

Buck converters 2 and 3 feature current limit that protects the device against short-circuit and overload conditions at their outputs. The current-limit value is dependent on the version selected, 1.5A or 3.0A (max) DC current. See the Selector Guide for the current-limit value of the chosen option and the Electrical Characteristics table for the corresponding current limit. In the event of a shortcircuit or overload condition at an output, the high-side MOSFET remains on until the inductor current reaches the high-side MOSFET's current-limit threshold. The converter then turns on the low-side MOSFET and the inductor current ramps down.
The converter allows the low-side MOSFET to turn off only when the inductor current ramps down to the lowside MOSFET's current threshold. This cycle repeats until the short or overload condition is removed.

## Applications Information

## OUT1 Adjustable Output-Voltage Option

The device's adjustable output-voltage version (see the Selector Guide for details) allows the customer to set OUT1 voltage between 3.0 V and 5.5 V . Connect a resistive divider from OUT1 to FB1 to GND to set the output voltage (Figure 3). Select R2 (FB1 to GND resistor) less than or equal to $100 \mathrm{k} \Omega$. Calculate R1 (VOUT1 to FB1 resistor) with the following equation:

$$
\mathrm{R}_{1}=\mathrm{R}_{2}\left[\left(\frac{\mathrm{~V}_{\mathrm{OUT} 1}}{\mathrm{~V}_{\mathrm{FB} 1}}\right)-1\right]
$$

where $\mathrm{V}_{\mathrm{FB} 1}=1 \mathrm{~V}$ (see the Electrical Characteristics table).
The external feedback resistive divider must be frequency compensated for proper operation. Place a capacitor across R1 in the resistive divider network. Use the following equation to determine the value of the capacitor:

$$
\text { if } R 2 / R 1>1, C 1=C(R 2 / R 1)
$$

else, C1 = C, where $C=10 \mathrm{pF}$.

For fixed-output options, connect FB1 to BIAS for the factory-programmed, fixed-output voltage. Connect FB1 to GND for a fixed 3.3 V output voltage.

## OUT1 Current-Sense Resistor Selection

Choose the current-sense resistor based on the maximum inductor current ripple factor (KINDMAX) and minimum cur-rent-limit threshold across current-sense resistor (VLIM1MIN $=0.1 \mathrm{~V}$ ).
The formula for calculating the current-sense resistor is:

$$
\operatorname{Rcs}_{\text {MAX }}=\frac{\mathrm{V}_{\text {LIM 1MIN }}}{\mathrm{I}_{\text {OUTMAX }} \times\left(1+\frac{\mathrm{K}_{\text {INDMAX }}}{2}\right)}
$$

where IOUTMAX is the maximum load current for Buck 1 and KINDMAX is the maximum inductor current ripple factor. The maximum inductor current ripple factor is a function of the inductor chosen, as well as the operating conditions, and is typically chosen between 0.3 and 0.4 :

$$
\mathrm{K}_{\text {INDMAX }}=\frac{\left(\mathrm{V}_{\text {SUP }}-\mathrm{V}_{\text {OUT }}\right) \times \mathrm{D}}{I_{\text {OUTMAX }} \times \mathrm{f}_{\text {SW }}[\mathrm{MHZ}] \times \mathrm{L}[\mu \mathrm{H}]}
$$

where $D$ is the duty cycle. Below is a numerical example to calculate the current-sense resistor in Figure 3. The maximum inductor current ripple factor is chosen at the maximum supply voltage $(36 \mathrm{~V})$ to be 0.4 :

$$
\begin{aligned}
\operatorname{Rcs}_{\text {MAX }} & =\frac{0.1}{\text { IOUTMAX } \times\left(1+\frac{\mathrm{K}_{\text {INDMAX }}}{2}\right)} \\
& =\frac{0.1}{5 \times\left(1+\frac{0.4}{2}\right)}=0.0166 \Omega
\end{aligned}
$$

Figure 3. Adjustable OUT1 Voltage Configuration

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## OUT1 Inductor Selection

Three key inductor parameters must be specified for operation with the device: inductance value (L), inductor saturation current (ISAT), and DC resistance (RDCR). Use the following formulas to determine the minimum inductor value:

$$
\mathrm{L}_{\text {MIN } 1}[\mathrm{H}]=1.3 \times\left[\begin{array}{l}
\left(\mathrm{V}_{\text {SUPMAX }}-\mathrm{V}_{\text {OUT } 1}\right) \times\left(\frac{\mathrm{V}_{\text {OUT } 1}}{\mathrm{~V}_{\text {SUPMAX }}}\right) \\
\times\left(\frac{1}{\mathrm{f}_{\text {SW } 1} \times \mathrm{I}_{\text {OUTMAX }} \times \mathrm{K}_{\text {INDMAX }}}\right)
\end{array}\right]
$$

where fSW1 is the operating frequency and 1.3 is a coefficient that accounts for inductance initial precision. or:

$$
\begin{gathered}
\mathrm{L}_{\mathrm{MIN} 2}[\mu \mathrm{H}]=1.3 \times \frac{\mathrm{V}_{\mathrm{OUT} 1}}{0.8} \times \mathrm{R}_{\mathrm{CS}} \\
\times \mathrm{A}_{\mathrm{V}_{-} \mathrm{CS}} \times \frac{2.1 \times 10^{6}}{\mathrm{f}_{\mathrm{SW} 1}}
\end{gathered}
$$

where $A V \_$cs is current-sense amplifier gain ( $8 \mathrm{~V} / \mathrm{V}$, typ). For proper operation, the chosen inductor value must be greater than or equal to $L_{\text {MIN1 }}$ and $L_{\text {MIN2 }}$. The maximum inductor value recommended is twice the chosen value from the above formulas.
Table 1 lists some of the inductor values for 5A output current and several switching frequencies and output voltages.

## Buck 1 Input Capacitor

The device is designed to operate with a single $0.1 \mu \mathrm{~F}$ capacitor on the $\mathrm{V}_{\text {SUP }}$ input and a single $0.1 \mu \mathrm{~F}$ capacitoronthePV1 input. Placethesecapacitors ascloseas possible to their corresponding inputs to ensure the best EMI and jitter performance.

## OUT1 Output Capacitor

The primary purpose of the OUT1 output capacitor is to reduce the change in VOUT1 during load transient conditions. The minimum capacitor depends on the output voltage, maximum current, and load regulation accuracy. Use the following formula to determine the minimum output capacitor for Buck 1:

$$
\mathrm{C}_{\mathrm{OUT}} \geq \frac{\mathrm{I}_{\mathrm{OUT} 1(\mathrm{MAX})}}{2 \pi \times \mathrm{f}_{\mathrm{CO}} \times \Delta \mathrm{V}_{\mathrm{OUT} 1}}
$$

where $f_{C O}$ is the crossover frequency set by $R_{C}$ and $C_{C}$, and $\Delta \mathrm{V}_{\text {OUT1 }}$ is the allowable undershoot/overshoot voltage during a load transient condition in V unit.
For proper functionality, ceramic capacitors must be used. To avoid instability, make sure that the self-resonance of the ceramic capacitors is above 1 MHz .

## Buck 1 MOSFET Selection

Buck 1 drives two external logic-level n-channel MOSFETs as the circuit switch elements. The key selection parameters to choose these MOSFETs are:

- On-resistance ( $\mathrm{RDS}_{\mathrm{D}(\mathrm{ON})}$ )
- Maximum drain-to-source voltage ( $\mathrm{V}_{\mathrm{DS}}(\mathrm{MAX})$ )
- Minimum threshold voltage $\left(\mathrm{V}_{\mathrm{TH}(\mathrm{MIN})}\right)$
- Total gate charge $\left(Q_{G}\right)$
- Reverse transfer capacitance ( $\mathrm{C}_{\mathrm{RSS}}$ )
- Power dissipation

Both n-channel MOSFETs must be logic-level types with guaranteed on-resistance specifications at $\mathrm{V}_{\mathrm{GS}}=4.5 \mathrm{~V}$ when $\mathrm{V}_{\text {OUT1 }}$ is set to 5 V or $\mathrm{V}_{\mathrm{GS}}=3 \mathrm{~V}$ when $\mathrm{V}_{\text {OUT1 }}$ is set to 3.3 V . The conduction losses at minimum input voltage should not exceed MOSFET package thermal limits or violate the overall thermal budget. Also, ensure that the conduction losses plus switching losses at the maximum input voltage do not exceed package ratings or violate the overall thermal budget. In particular, check that the dV/dt caused by DH1 turning on does not pull up the DL1 gate through its drain-to-gate capacitance. This is the most frequent cause of cross-conduction problems.

Table 1. Inductor Values vs. (VSUPMAX, VOUT1)

| $\mathbf{V}_{\text {SUPMAX }}$ to $\mathbf{V}_{\text {OUT1 }}(\mathbf{V})$ | $\mathbf{V}_{\text {SUPMAX }}=\mathbf{3 6 V}, \mathbf{V}_{\text {OUT1 }}=\mathbf{5 V}$ |  |  |  | $\mathbf{V}_{\text {SUPMAX }}=\mathbf{3 6 V}, \mathbf{V}_{\text {OUT1 }}=\mathbf{3 . 3 V}$ |  |  |  |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

Gate-charge losses are dissipated by the driver and do not heat the MOSFET; therefore, the power dissipation in the device due to drive losses must be checked. Both MOSFETs must be selected so that their total gate charge is low enough; therefore, $\mathrm{PV} 1 / \mathrm{V}_{\text {OUT1 }}$ can power both drivers without overheating the device:

$$
\text { PDRIVE }=V_{\text {OUT1 }} \times\left(Q_{G T O T H}+Q_{G T O T L}\right) \times f_{S W 1}
$$

where $Q_{G T O T L}$ is the low-side MOSFET total gate charge and $Q_{G T O T H}$ is the high-side MOSFET total gate charge. Select MOSFETs with a $Q_{G}$ total of less than $10 n C$.
The n-channel MOSFETs must deliver the average current to the load and the peak current during switching. Dual MOSFETs in a single package can be an economical solution. To reduce switching noise for smaller MOSFETs, use a series resistor in the DH1 path and additional gate capacitance. Contact the factory for guidance using gate resistors.

## Compensation Network

The device uses a current-mode-control scheme that regulates the output voltage by forcing the required current through the external inductor, so the controller uses the voltage drop across the DC resistance of the inductor or the alternate series current-sense resistor to measure the inductor current. Current-mode control eliminates the double pole in the feedback loop caused by the inductor and output capacitor, resulting in a smaller phase shift, and requiring less elaborate error-amplifier compensation than voltage-mode control. A single series resistor $\left(\mathrm{R}_{\mathrm{C}}\right)$ and capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ is all that is required to have a stable, high-bandwidth loop in applications where ceramic capacitors are used for output filtering (see Figure 4). For other types of capacitors, due to the higher capacitance and ESR, the frequency of the zero created by the capacitance and ESR is lower than the desired closed-loop crossover frequency. To stabilize a nonceramic output capacitor loop, add another compensation capacitor ( $\mathrm{C}_{\mathrm{F}}$ ) from COMP1 to GND to cancel this ESR zero.
The basic regulator loop is modeled as a power modulator, output feedback divider, and an error amplifier (see Figure 4). The power modulator has a DC gain set by $g_{m c} \times R_{\text {LOAD }}$, with a pole and zero pair set by R ROAD, the output capacitor (COUT), and its ESR. The loop response is set by the following equation:

$$
\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{dc})}=g_{\mathrm{mc}} \times \mathrm{R}_{\mathrm{LOAD}}
$$

where $R_{\text {LOAD }}=V_{\text {OUT }} / l_{O U T}(M A X)$ in $\Omega$ and $g_{m c}=1 /\left(\mathrm{A}_{\mathrm{V}} \mathrm{CS}\right.$ $\left.x R_{D C}\right)$ in $S$. $A_{V}$ _cs is the voltage gain of the current-sense amplifier and is typically $8 \mathrm{~V} / \mathrm{V} . R_{D C}$ is the DC resistance of the inductor or the current-sense resistor in $\Omega$.

In a current-mode step-down converter, the output capacitor and load resistance introduce a pole at the following frequency:

$$
\mathrm{f}_{\mathrm{pMOD}}=\frac{1}{2 \pi \times \mathrm{C}_{\mathrm{OUT}} \times \mathrm{R}_{\mathrm{LOAD}}}
$$

The unity-gain frequency of the power stage is set by Cout and $\mathrm{gmc}_{\mathrm{m}}$ :

$$
\mathrm{f}_{\mathrm{UGAINpMOD}}=\frac{\mathrm{g}_{\mathrm{mc}}}{2 \pi \times \mathrm{C}_{\mathrm{OUT}}}
$$

The output capacitor and its ESR also introduce a zero at:

$$
\mathrm{f}_{\mathrm{zMOD}}=\frac{1}{2 \pi \times \mathrm{ESR} \times \mathrm{C}_{\mathrm{OUT}}}
$$

When CoUt is composed of "n" identical capacitors in parallel, the resulting COUT $=n \times C_{O U T}(E A C H)$, and ESR $=E S R(E A C H) / n$. Note that the capacitor zero for a parallel combination of like-value capacitors is the same as for an individual capacitor.
The feedback voltage-divider has a gain of GAIN $\mathrm{FBB}^{=}$ $\mathrm{V}_{\mathrm{FB}} / \mathrm{V}_{\text {OUT }}$, where $\mathrm{V}_{\mathrm{FB}}$ is 1 V (typ).
The transconductance error amplifier has a DC gain of $\operatorname{GAIN}_{\mathrm{EA}(\mathrm{DC})}=g_{m, E A} \times$ ROUT,EA, where $g_{m, E A}$ is the error-amplifier transconductance, which is $660 \mu \mathrm{~S}$ (typ), and ROUT,EA is the output resistance of the error amplifier, which is $30 \mathrm{M} \Omega$ (typ).

Figure 4. Compensation Network

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

A dominant pole ( $f_{d p E A}$ ) is set by the compensation capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$ and the amplifier output resistance (ROUT,EA). A zero (fZEA) is set by the compensation resistor $\left(R_{C}\right)$ and the compensation capacitor $\left(\mathrm{C}_{\mathrm{C}}\right)$. There is an optional pole (fPEA) set by $\mathrm{C}_{F}$ and $\mathrm{R}_{\mathrm{C}}$ to cancel the output capacitor ESR zero if it occurs near the crossover frequency ( $\mathrm{f}_{\mathrm{C}}$, where the loop gain equals $1(0 \mathrm{~dB})$ ).
Thus:

$$
\begin{aligned}
& \mathrm{f}_{\mathrm{dpEA}}= \frac{1}{2 \pi \times \mathrm{C}_{\mathrm{C}} \times\left(\mathrm{R}_{\mathrm{OUT}, \mathrm{EA}}+\mathrm{R}_{\mathrm{C}}\right)} \\
& \mathrm{f}_{\mathrm{zEA}}=\frac{1}{2 \pi \times \mathrm{C}_{\mathrm{C}} \times \mathrm{R}_{\mathrm{C}}} \\
& \mathrm{f}_{\mathrm{pEA}}=\frac{1}{2 \pi \times \mathrm{C}_{\mathrm{F}} \times \mathrm{R}_{\mathrm{C}}}
\end{aligned}
$$

The loop-gain crossover frequency ( $\mathrm{f}_{\mathrm{C}}$ ) should be set below $1 / 5$ of the switching frequency and much higher than the power-modulator pole ( $\mathrm{f}_{\mathrm{pMOD}}$ ). Select a value for $f_{C}$ in the range:

$$
\mathrm{f}_{\mathrm{pMOD}} \ll \mathrm{f}_{\mathrm{C}} \leq \frac{\mathrm{f}_{\mathrm{SW}}}{10}
$$

At the crossover frequency, the total loop gain must be equal to 1.
Thus:

$$
\begin{gathered}
\operatorname{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)} \times \frac{\mathrm{V}_{\mathrm{FB}}}{\mathrm{~V}_{\mathrm{OUT}}} \times \operatorname{GAIN}_{\mathrm{EA}\left(\mathrm{f}_{\mathrm{C}}\right)}=1 \\
\operatorname{GAIN} \\
\operatorname{GAA}_{\left(\mathrm{f}_{\mathrm{C}}\right)}=\mathrm{g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}} \\
{\operatorname{GAOD}\left(\mathrm{f}_{\mathrm{C}}\right)}=\operatorname{GAIN}_{\mathrm{MOD}(\mathrm{dc})} \times \frac{f_{\mathrm{pMOD}}}{\mathrm{f}_{\mathrm{C}}}
\end{gathered}
$$

Therefore:

$$
\operatorname{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)} \times \frac{\mathrm{V}_{\mathrm{FB}}}{V_{\mathrm{OUT}}} \times g_{\mathrm{m}, \mathrm{EA}} \times \mathrm{R}_{\mathrm{C}}=1
$$

Solving for $\mathrm{R}_{\mathrm{C}}$ :

$$
\mathrm{R}_{\mathrm{C}}=\frac{\mathrm{V}_{\mathrm{OUT}}}{\mathrm{~g}_{\mathrm{m}, \mathrm{EA}} \times \mathrm{V}_{\mathrm{FB}} \times \mathrm{GAIN}_{\mathrm{MOD}\left(\mathrm{f}_{\mathrm{C}}\right)}}
$$

Set the error-amplifier compensation zero formed by $R_{C}$ and $C_{C}$ at the $f_{p M O D}$. Calculate the value of $C_{C}$ as follows:

$$
\mathrm{C}_{\mathrm{C}}=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{pMOD}} \times \mathrm{R}_{\mathrm{C}}}
$$

If $\mathrm{f}_{\mathrm{ZMOD}}$ is less than $5 \times \mathrm{f}_{\mathrm{C}}$, add a second capacitor $\mathrm{C}_{\mathrm{F}}$ from COMP1 to GND. The value of $C_{F}$ is:

$$
C_{F}=\frac{1}{2 \pi \times f_{z M O D} \times R_{C}}
$$

As the load current decreases, the modulator pole also decreases; however, the modulator gain increases accordingly and the crossover frequency remains the same.
Belowisanumericalexampletocalculatethe compensationnetwork component values of Figure 4:

$$
\begin{gathered}
\mathrm{A}_{\mathrm{V} \_\mathrm{CS}}=8 \mathrm{~V} / \mathrm{V} \\
\mathrm{R}_{\mathrm{DCR}}=22 \mathrm{~m} \Omega \\
\mathrm{gmC}_{\mathrm{mc}}=1 /\left(\mathrm{A}_{\mathrm{V} \_\mathrm{CS}} \times \mathrm{R}_{\mathrm{DC}}\right)=1 /(8 \times 0.022)=5.68 \\
\mathrm{~V}_{\mathrm{OUT}}=5 \mathrm{~V} \\
\mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})}=5 \mathrm{~A} \\
\mathrm{R}_{\text {LOAD }}=\mathrm{V}_{\mathrm{OUT} / \mathrm{lOUT}(\mathrm{MAX})}=5 \mathrm{~V} / 6 \mathrm{~A}=0.833 \Omega \\
\mathrm{C}_{\mathrm{OUT}}=4 \times 47 \mu \mathrm{~F}=188 \mu \mathrm{~F} \\
\mathrm{ESR}=9 \mathrm{~m} \Omega / 4=2.25 \mathrm{~m} \Omega \\
\mathrm{fSW}=0.420 \mathrm{MHz} \\
\mathrm{GAIN}_{\mathrm{MOD}(\mathrm{dc})}=5.68 \times 0.833=4.73 \\
\mathrm{f}_{\mathrm{pMOD}}=\frac{1}{2 \pi \times 188 \mu \mathrm{~F} \times 0.833} \approx 1 \mathrm{kHz} \\
\mathrm{f}_{\mathrm{pMOD}} \ll \mathrm{f} \mathrm{C} \leq \frac{\mathrm{f}_{\mathrm{SW}}}{10}
\end{gathered}
$$

$$
1 \mathrm{kHz} \ll \mathrm{f}_{\mathrm{C}} \leq 42 \mathrm{kHz}, \text { Select } \mathrm{f}_{\mathrm{C}}=20 \mathrm{kHz}
$$

$$
\mathrm{f}_{\mathrm{ZMOD}}=\frac{1}{2 \pi \times 2.25 \mathrm{~m} \Omega \times 188 \mu \mathrm{~F}} \approx 376 \mathrm{kHz}
$$

Since $f_{Z M O D}>f_{C}$ :

$$
\begin{aligned}
\mathrm{R}_{\mathrm{C}} & \approx 33 \mathrm{k} \Omega \\
\mathrm{C}_{\mathrm{C}} & \approx 4.7 \mathrm{nF} \\
\mathrm{C}_{\mathrm{F}} & \approx 12 \mathrm{pF}
\end{aligned}
$$

## Step-Down Controller with Dual 2.1 MHz Step-Down DC-DC Converters

## OUT2/OUT3 Adjustable Output-Voltage Option

The device's adjustable output-voltage version (see the Selector Guide for details) allows the customer to set the outputs to any voltage between 0.8 V and 3.95 V . Connect a resistive divider from the buck converter output (VOUT_(BUCK)) to OUT_ to GND to set the output voltage (Figure 5). Select R4 (OUT_ to GND resistor) less than or equal to $100 \mathrm{k} \Omega$. Calculate R3 (VOUT_(BUCK) to OUT_ resistor) with the following equation:

$$
\mathrm{R} 3=\mathrm{R} 4\left[\left(\frac{\left.\mathrm{~V}_{\text {OUT_( }} \text { BUCK }\right)}{\mathrm{V}_{\text {OUT_}}}\right)-1\right]
$$

where $\mathrm{V}_{\text {OUT_ }}=0.802 \mathrm{mV}$ (see the Electrical Characteristics table).
The external feedback resistive divider must be frequency compensated for proper operation. Place a capacitor in parallel to R3 in the resistive-divider network. Use the following equation to determine the value of the capacitor:

$$
\text { if } R 4 / R 3>1, C 2=C(R 4 / R 3)
$$

else, $C 2=C$, where $C=10 \mathrm{pF}$.
For fixed output-voltage options, connect OUT_ to VOUT_ for the factory-programmed, fixed-output voltage between 0.8 V and 3.95 V .

## OUT2/OUT3 Inductor Selection

Three key inductor parameters must be specified for operation with the device: inductance value (L), inductor saturation current (ISAT), and DC resistance (RDCR). To select inductor value, the ratio of inductor peak-to-peak AC current to DC average current (LIR) must be selected first. A good compromise between size and loss is a 30\% peak-to-peak ripple current to average-current ratio (LIR $=0.3$ ). The switching frequency, input voltage, output voltage, and selected LIR then determine the inductor value as follows:

$$
\begin{aligned}
\mathrm{L}_{\mathrm{MIN}}= & \left(\left(\mathrm{V}_{\mathrm{OUT} 1}-\mathrm{V}_{\text {OUT_ }}\right) \times \mathrm{V}_{\text {OUT_ }}\right) /\left(\mathrm{V}_{\text {OUT1 }} \times\right. \\
& 2.1 \mathrm{MHz} \times \text { lout(MAX) } \times \text { LIR })
\end{aligned}
$$

where $\mathrm{V}_{\text {OUT1 }}$, $\mathrm{V}_{\text {OUT_, }}$, and $\mathrm{I}_{\text {OUT(MAX) }}$ are typical values and are the maximum output current capability of the output (3A or 1.5 A ). The inductor value should also not be too large to guarantee there is enough ripple current in the feedback loop:

$$
\mathrm{L}_{\mathrm{MAX}}=2 \times \mathrm{L}_{\mathrm{MIN}}
$$

Select a typical inductor value between and the first standard value greater than is usually the best choice, as it provides the best transient performance and smallest size inductor:

$$
\mathrm{L}_{\mathrm{MIN}} \leq \mathrm{L} \leq \mathrm{L}_{\mathrm{MAX}}
$$

OUT2/OUT3 Input Capacitor
Place a single $4.7 \mu \mathrm{~F}$ ceramic bypass capacitor on the PV2 and PV3 inputs. Phase interleaving of the two low-voltage buck converters contributes to a lower required input capacitance by cancelling input ripple currents. Place the bypass capacitors as close as possible to their corresponding PV_ input to ensure the best EMI and jitter performance.

## OUT2/OUT3 Output Capacitor

The minimum capacitor required depends on output voltage. Use the following formula to determine the required output capacitance value:

$$
\mathrm{C}_{\text {OUT(MIN })}=\left(40 \times \mathrm{I}_{\text {MAX }} \mathrm{V}_{\text {OUT_ }}\right) \mu \mathrm{F}
$$

Figure 5. Adjustable OUT2/OUT3 Voltage Configuration
Table 2. Inductor Values vs. (VPV_, VOUT)

| $\mathrm{V}_{\text {PV_ }}$ TO $\mathrm{V}_{\text {OUT }}(\mathrm{V})$ | $\begin{gathered} \mathrm{V}_{\mathrm{PV} 2 / 3}=5.5 \mathrm{~V}, \\ \mathrm{~V}_{\mathrm{OUT} 2 / 3}=3.3 \mathrm{~V} \end{gathered}$ | $\begin{gathered} \mathrm{V}_{\mathrm{PV} 2 / 3}=5.5 \mathrm{~V}, \\ \mathrm{~V}_{\mathrm{OUT} 2 / 3}=2.5 \mathrm{~V} \end{gathered}$ | $\begin{gathered} \mathrm{V}_{\mathrm{PV} 2 / 3}=5.5 \mathrm{~V}, \\ \mathrm{~V}_{\mathrm{OUT} 2 / 3}=1.5 \mathrm{~V} \end{gathered}$ | $\begin{gathered} \mathrm{V}_{\mathrm{PV} 2 / 3}=3.0 \mathrm{~V}, \\ \mathrm{~V}_{\mathrm{OUT} 2 / 3}=0.8 \mathrm{~V} \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: |

| INDUCTOR ( $\mu \mathrm{H}$ ), ILOAD $=3.0 \mathrm{~A}$ | 1.0 | 0.68 | 0.56 | 0.33 |

## Step-Down Controller with Dual 2.1 MHz

 Step-Down DC-DC Converters initial, life, and temperature. When using $\pm 20 \%$ X7R capacitors with adequate working voltage, the nominal output capacitance should total around 1.4 times the minimum value:$$
\text { Cout(NOM) }=\text { COUT(MIN) } \times 1.4
$$

For proper functionality, ceramic capacitors must be used; make sure that the self-resonance of the ceramic capacitors at the converters' output converter is above 1 MHz to avoid instability.

## Thermal Considerations

How much power the package can dissipate strongly depends on the mounting method of the IC to the PCB and the copper area for cooling. Using the JEDEC test standard, the maximum power dissipation allowed is 2759mW in the TQFN package. More power dissipation can be handled by the package if great attention is given during PCB layout. For example, using the top and bottom copper as a heatsink and connecting the thermal vias to one of the middle layers (GND) transfers the heat from the package into the board more efficiently, resulting in lower junction temperature at high power dissipation in some MAX20028 applications. Furthermore, the solder mask around the IC area on both top and bottom layers can be removed to radiate the heat directly into the air. The maximum allowable power dissipation in the IC is as follows:

$$
\mathrm{P}_{\mathrm{MAX}}=\frac{\left(\mathrm{T}_{\mathrm{J}(\mathrm{MAX})}-\mathrm{T}_{\mathrm{A}}\right)}{\theta_{\mathrm{JC}}+\theta_{\mathrm{CA}}}
$$

where $T_{J(M A X)}$ is the maximum junction temperature $\left(+150^{\circ} \mathrm{C}\right), \mathrm{T}_{\mathrm{A}}$ is the ambient air temperature, $\theta_{\mathrm{JC}}$ is the thermal resistance from the junction to the case, and $\theta_{\mathrm{CA}}$ is the thermal resistance from the case to the surrounding air through the PCB, copper traces, and the package materials. $\theta_{\mathrm{CA}}$ is directly related to system-level variables and can be modified to increase the maximum power dissipation. The TQFN package has an exposed thermal pad on its underside. This pad provides a low thermalresistance path for heat transfer into the PCB. This low
thermally resistive path carries a majority of the heat away from the IC. The PCB is effectively a heatsink for the IC. The exposed pad should be connected to a large ground plane for proper thermal and electrical performance. The minimum size of the ground plane is dependent upon many system variables. To create an efficient path, the exposed pad should be soldered to a thermal landing and connected to the ground plane by thermal vias. The thermal landing should be at least as large as the exposed pad and can be made larger depending on the amount of free space from the exposed pad to the other pin landings. A sample layout is available on the MAX20028 evaluation kit to speed designs.

## PCB Layout Guidelines

Careful PCB layout is critical to achieve low switching losses and clean, stable operation. Use a multilayer board whenever possible for better noise immunity and power dissipation. Follow these guidelines for good PCB layout:

1) Use a large contiguous copper plane under the device package. Ensure that all heat-dissipating components have adequate cooling.
2) Isolate the power components and high-current path from the sensitive analog circuitry. This is essential to prevent any noise coupling into the analog signals.
3) Keep the high-current paths short, especially at the ground terminals. This practice is essential for stable, jitter-free operation. The high-current path comprising input capacitor, high-side FET, inductor, and the output capacitor should be as short as possible.
4) Keep the power traces and load connections short. This practice is essential for high efficiency. Use thick copper PCBs (2oz vs. 10z) to enhance full-load efficiency.
5) The analog signal lines should be routed away from the high-frequency planes. This ensures integrity of sensitive signals feeding back into the device.
6) Use a single ground plane to reduce the chance of ground-potential differences. With a single ground plane, enough isolation between analog return signals and high-power signals must be maintained.

## Typical Application Circuit

## Selector Guide

| OPTION | BUCK 1 |  |  | BUCK 2 |  |  | BUCK 3 |  |  | SYNC |

## Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE |
| :---: | :---: | :---: |
| MAX20028ATJ_NY+ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 32 TQFN-EP** |

Note: Insert the desired option letter (from the Selector Guide) into the blank to indicate buck switching frequency, active timeout period, fixed or adjustable output voltages, maximum output current, and SYNC functionality.
IV denotes an automotive qualified part.
+Denotes a lead(Pb)-free/RoHS-compliant package.
**EP = Exposed pad.
Contact factory for options that are not included.
Factory-selectable features include:

- $f_{S W 1}$ divide ratio with respect to master clock
- DC-DC output voltage
- Number of cycles in active timeout period
- Independent current limit for each channel up to 3A
- SYNC input

## Package Information

For the latest package outline information and land patterns (footprints), go to www.maximintegrated.com/packages. Note that a "+", "\#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

| PACKAGE <br> TYPE | PACKAGE <br> CODE | OUTLINE <br> NO. | LAND <br> PATTERN NO. |
